21. (*a*) A pressure cooker, by definition, increases the pressure on what is inside it. An increased pressure yields a higher boiling point. The water in which the food is usually prepared will boil at a higher temperature than normal, thereby cooking the food faster. (*b*) At high altitudes, the atmospheric pressure is less than it is at sea level. If atmospheric pressure decreases, the boiling point of water will decrease. Boiling occurs at a lower temperature. Food (including pasta and rice) will need to cook longer at this lower temperature to be properly prepared. (*c*) It is actually easier to boil water at higher altitude, because it boils at a lower temperature.

22. Both "vapor" and "gas" refer to a substance in the gaseous state. They differ in that a vapor is below the critical temperature and a gas is above the critical temperature for the substance.

23. (*a*) Yes. As an example, think of ice skating. The pressure from the weight of the skater melts the ice, and the skater glides on a thin layer of water.
(*b*) No. See Figure 18-6. The solid–liquid interface has a positive slope, and so it is not possible to melt carbon dioxide simply by applying pressure.

24. Dry ice is carbon dioxide in the solid state. As shown in Figure 18-6, carbon dioxide at room temperature will be a vapor unless it is at a pressure several times atmospheric pressure. When brought to room temperature, the dry ice sublimates and therefore does not last long.

25. Liquid CO_2 can exist at temperatures between –56.6ºC and 31ºC and pressures between 5.11 atm and 73 atm. (See Figure 18-6.) CO_2 can exist as a liquid at normal room temperature, if the pressure is between 56 and 73 atm.

26. Exhaled air contains a large amount of water vapor and is initially at a temperature equal to body temperature. When the exhaled air comes into contact with the external air on a cold day it cools rapidly and reaches the dew point. At the dew point temperature, the air can no longer hold all the water vapor and water condenses into little droplets, forming a cloud.

27. A sound wave can be described as a pressure wave or a displacement wave. Transmission of the wave depends on the collisions of the gas molecules and their displacements away from an equilibrium position. If the wavelength of a sound wave is less than or equal to the mean free path of the molecules in a gas, then there is no net displacement from the equilibrium position and the sound wave will be "lost" in the movement of the molecules. The forces between the molecules will not be large enough to transmit the sound wave.

28. Ways to reduce the mean free path in a gas include increasing the size of the gas molecules and increasing the density of the gas. Gas density can be increased either by increasing the number of molecules or by decreasing the volume.

Solutions to Problems

In solving these problems, the authors did not always follow the rules of significant figures rigidly. We tended to take quoted temperatures as correct to the number of digits shown, especially where other values might indicate that.

1. (*a*) The average translational kinetic energy of a gas molecule is $\frac{3}{2}kT$.

$$K_{\text{avg}} = \tfrac{3}{2}kT = \tfrac{3}{2}\left(1.38\times10^{-23}\,\text{J/K}\right)\left(273\,\text{K}\right) = \boxed{5.65\times10^{-21}\,\text{J}}$$

(*b*) The total translational kinetic energy is the average kinetic energy per molecule, times the number of molecules.

$$KE_{\text{total}} = N\left(KE_{\text{avg}}\right) = \left(1.0\,\text{mol}\right)\left(\frac{6.02\times10^{23}\,\text{molecules}}{1}\right)\tfrac{3}{2}\left(1.38\times10^{-23}\,\text{J/K}\right)\left(298\,\text{K}\right)$$

$$= \boxed{3700\,\text{J}}$$

2. The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$. Helium has an atomic mass of 4.0.

$$v_{\text{rms}} = \sqrt{3kT/m} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(6000\text{ K}\right)}{4.0\left(1.66\times10^{-27}\,\text{kg}\right)}} = 6116\,\text{m/s} \approx \boxed{6\times10^{3}\,\text{m/s}}$$

3. The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$. The temperature must be in Kelvins.

$$\frac{\left(v_{\text{rms}}\right)_2}{\left(v_{\text{rms}}\right)_1} = \frac{\sqrt{3kT_2/m}}{\sqrt{3kT_1/m}} = \sqrt{\frac{T_2}{T_1}} = \sqrt{\frac{453\text{ K}}{273\text{ K}}} = \boxed{1.29}$$

4. The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$. Since the rms speed is proportional to the square root of the absolute temperature, to triple the rms speed without changing the mass, the absolute temperature must be multiplied by a factor of 9.

$$T_{\text{fast}} = 4T_{\text{slow}} = 9\left(273+20\right)\text{K} = 2637\text{ K} = \boxed{2364°\text{C}}$$

5. The average kinetic molecular energy is $\frac{3}{2}kT$. Set this equal to the kinetic energy of the paper clip.

$$\tfrac{1}{2}mv^2 = \tfrac{3}{2}kT \quad\rightarrow\quad v = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(288\,\text{K}\right)}{1.0\times10^{-3}\,\text{kg}}} = \boxed{3.5\times10^{-9}\,\text{m/s}}$$

6. (*a*) The average molecular kinetic energy is $\frac{3}{2}kT$, so the total kinetic energy for a mole would be Avogadro's number times $\frac{3}{2}kT$.

$$K = N_0\left(\tfrac{3}{2}kT\right) = \tfrac{3}{2}RT = \tfrac{3}{2}\left(8.314\,\text{J/mol•K}\right)\left(273\,\text{K}+15\,\text{K}\right) = \boxed{3740\text{ J}}$$

(*b*) $K = \tfrac{1}{2}mv^2 = 3704\,\text{J} \quad\rightarrow\quad v = \sqrt{\dfrac{2\left(3740\,\text{J}\right)}{65\,\text{kg}}} = \boxed{11\,\text{m/s}}$

7. The mean (average) speed is as follows.

$$v_{\text{avg}} = \frac{6.0 + 2.0 + 4.0 + 6.0 + 0.0 + 4.0 + 1.0 + 8.0 + 5.0 + 3.0 + 7.0 + 8.0}{12} = \frac{54.0}{12} = \boxed{4.5}.$$

The rms speed is the square root of the mean (average) of the squares of the speeds.

$$v_{\text{rms}} = \sqrt{\frac{6.0^2 + 2.0^2 + 4.0^2 + 6.0^2 + 0.0^2 + 4.0^2 + 1.0^2 + 8.0^2 + 5.0^2 + 3.0^2 + 7.0^2 + 8.0^2}{12}}$$

$$= \sqrt{\frac{320}{12}} = \boxed{5.2}$$

8. The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$.

$$\frac{(v_{\text{rms}})_2}{(v_{\text{rms}})_1} = 1.020 = \frac{\sqrt{3kT_2/m}}{\sqrt{3kT_1/m}} = \sqrt{\frac{T_2}{T_1}} \quad \rightarrow$$

$$T_2 = T_1(1.020)^2 = (293.15\,\text{K})(1.020)^2 = 305.0\,\text{K} = \boxed{31.8°\text{C}}$$

9. From the ideal gas law, $PV = nRT$, if the volume and amount of gas are held constant, the temperature is proportional to the pressure, $PV = nRT \rightarrow P = \frac{nR}{V}T = (\text{constant})T$. Thus the temperature will be tripled. Since the rms speed is proportional to the square root of the temperature, $v_{\text{rms}} = \sqrt{3kT/m} = (\text{constant})\sqrt{T}$, v_{rms} will be multiplied by a factor of $\boxed{\sqrt{3}} \approx 1.73$.

10. The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$. The temperature can be found from the ideal gas law, $PV = NkT \rightarrow kT = PV/N$. The mass of the gas is the mass of a molecule times the number of molecules: $M = Nm$, and the density of the gas is the mass per unit volume, $\rho = \frac{M}{V}$. Combining these relationships gives the following.

$$v_{\text{rms}} = \sqrt{3kT/m} = \sqrt{\frac{3PV}{Nm}} = \sqrt{\frac{3PV}{M}} = \sqrt{\frac{3P}{\rho}}$$

11. The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$.

$$\frac{(v_{\text{rms}})_2}{(v_{\text{rms}})_1} = \frac{\sqrt{3kT/m_2}}{\sqrt{3kT/m_1}} \quad \rightarrow \quad \boxed{\frac{(v_{\text{rms}})_2}{(v_{\text{rms}})_1} = \sqrt{\frac{m_1}{m_2}}}$$

12. The temperature of the nitrogen gas is found from the ideal gas law, and then the rms speed is found from the temperature.

$$PV = nRT \rightarrow T = \frac{PV}{nR}$$

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3k}{m}\frac{PV}{nR}} = \sqrt{\frac{3(1.38\times10^{-23}\,\text{J/K})}{28(1.66\times10^{-27}\,\text{kg})}\frac{(3.1\,\text{atm})(1.013\times10^5\,\text{Pa/atm})(8.5\,\text{m}^3)}{(1800\,\text{mol})(8.314\,\text{J/mol•K})}}$$

$$= 398.6\,\text{m/s} \approx \boxed{4.0\times10^2\,\text{m/s}}$$

13. From Eq. 18-5, we have $v_{\text{rms}} = \sqrt{3kT/m}$.

(*a*) $$\frac{dv_{\text{rms}}}{dT} = \frac{d}{dT}\left(\frac{3kT}{m}\right)^{1/2} = \frac{1}{2}\left(\frac{3k}{m}\right)^{1/2}\frac{1}{T^{1/2}} = \frac{1}{2}\left(\frac{3kT}{m}\right)^{1/2}\frac{1}{T} = \boxed{\frac{1}{2}\frac{v_{\text{rms}}}{T}}$$

$$\Delta v_{\text{rms}} \approx \frac{dv_{\text{rms}}}{dT}\Delta T = \frac{1}{2}\frac{v_{\text{rms}}}{T}\Delta T \quad \rightarrow \quad \frac{\Delta v_{\text{rms}}}{v_{\text{rms}}} \approx \boxed{\frac{1}{2}\frac{\Delta T}{T}}$$

(*b*) The temperature must be calculated in Kelvin for the formula to be applicable. We calculate the percent change relative to the winter temperature.

$$\frac{\Delta v_{\text{rms}}}{v_{\text{rms}}} \approx \frac{1}{2}\frac{\Delta T}{T} = \frac{1}{2}\left(\frac{30\,\text{K}}{268\,\text{K}}\right) = 0.056 = \boxed{5.6\%}$$

14. Assume that oxygen is an ideal gas, and that each molecule occupies the same cubical volume of ℓ^3. Find the volume per molecule from the ideal gas law, and then the side length of that cubical molecular volume will be an estimate of the average distance between molecules.

$$PV = NkT \quad \rightarrow \quad \frac{V}{N} = \frac{kT}{P} = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)\left(273\,\text{K}\right)}{1.01\times10^{5}\,\text{Pa}} = 3.73\times10^{-26}\,\text{m}^3/\text{molecule}$$

$$\ell = \left(\frac{kT}{P}\right)^{1/3} = \left(\frac{\left(1.38\times10^{-23}\,\text{J/K}\right)\left(273\,\text{K}\right)}{1.01\times10^{5}\,\text{Pa}}\right)^{1/3} = \boxed{3.34\times10^{-9}\,\text{m}}$$

15. The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$.

$$\frac{\left(v_{\text{rms}}\right)_{^{235}\text{UF}_6}}{\left(v_{\text{rms}}\right)_{^{238}\text{UF}_6}} = \frac{\sqrt{3kT/m_{^{235}\text{UF}_6}}}{\sqrt{3kT/m_{^{238}\text{UF}_6}}} = \sqrt{\frac{m_{^{238}\text{UF}_6}}{m_{^{235}\text{UF}_6}}} = \sqrt{\frac{238+6(19)}{235+6(19)}} = \sqrt{\frac{352}{349}} = \boxed{1.004}$$

16. Gas molecules will rush into the vacuum from all directions. An estimate for the time for air to refill this vacuum region is the radius of the region divided by the rms speed of the molecules.

$$\Delta t = \frac{\Delta d}{v_{\text{rms}}} = \frac{\Delta d}{\sqrt{3kT/m}} = \frac{0.01\,\text{m}}{\sqrt{\dfrac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(293\,\text{K}\right)}{29\left(1.66\times10^{-27}\,\text{kg}\right)}}} = \boxed{2\times10^{-5}\,\text{s}}$$

17. (*a*) The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$.

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(273\,\text{K}\right)}{32\left(1.66\times10^{-27}\,\text{kg}\right)}} = \boxed{461\,\text{m/s}}$$

(*b*) Assuming that the particle has no preferred direction, then we have the following:

$$v_{\text{rms}}^2 = v_x^2 + v_y^2 + v_z^2 = 3v_x^2 \quad \rightarrow \quad v_x = v_{\text{rms}}/\sqrt{3}.$$

The time for one crossing of the room is then given by $t = d/v_x = \sqrt{3}d/v_{\text{rms}}$, and so the time for a round trip is $2\sqrt{3}d/v_{\text{rms}}$. Thus the number of back and forth round trips per second is the reciprocal of this time, $\dfrac{v_{\text{rms}}}{2\sqrt{3}d}$.

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\#\text{ round trips per sec} = \frac{v_{\text{rms}}}{2\sqrt{3}d} = \frac{461\,\text{m/s}}{2\sqrt{3}(5.0\text{ m})} = 26.6 \approx \boxed{26\text{ round trips per sec}}$$

18. (*a*) The average time for a molecule to travel from one side of the box to the other and back again is simply the round-trip distance, say in the *x* direction, divided by the average *x* speed of the molecule. The frequency of collisions for that molecule is the reciprocal of that round-trip time. The overall frequency of collisions is *N* times the frequency for a single particle. Use the ideal gas law to relate the number of particles in the room to the gas parameters of pressure, volume, and temperature.

$$t_{\substack{\text{round}\\\text{trip}}} = \frac{\Delta x}{\overline{v}_x} = \frac{2\ell}{\overline{v}_x} \quad ; \quad PV = NkT \quad \rightarrow \quad N = \frac{PV}{kT} = \frac{P\ell^3}{kT}$$

$$f = N\frac{1}{t_{\substack{\text{round}\\\text{trip}}}} = \frac{N\overline{v}_x}{2\ell} = \frac{\dfrac{P\ell^3}{kT}\overline{v}_x}{2\ell} = \boxed{\frac{\overline{v}_x}{2}\frac{P}{kT}\ell^2}$$

(*b*) We approximate that $\overline{v}_x \approx \sqrt{\overline{v_x^2}}$. From section 18-1, we have that $\overline{v_x^2} = \frac{1}{3}\overline{v^2}$ and Eq. 18-4, $\frac{1}{2}m\overline{v^2} = \frac{3}{2}kT$. Combine these results with the result from part (*a*).

$$f = \frac{\overline{v}_x}{2}\frac{P}{kT}\ell^2 \approx \frac{\sqrt{\overline{v_x^2}}}{2}\frac{P}{kT}\ell^2 = \frac{\sqrt{\frac{1}{3}\overline{v^2}}}{2}\frac{P}{kT}\ell^2 = \frac{\sqrt{\frac{1}{3}3\dfrac{\overline{kT}}{m}}}{2}\frac{P}{kT}\ell^2 = \boxed{\frac{P\ell^2}{\sqrt{4mkT}}}$$

(*c*) We assume the pressure is at one atmosphere, and we take the molecular mass of air to be 29 u, as given in problem 16.

$$f = \frac{P\ell^2}{\sqrt{4mkT}} = \frac{(1.013\times10^5\,\text{Pa})(3\text{m})^2}{\sqrt{4(29)(1.66\times10^{-27}\,\text{kg})(1.38\times10^{-23}\,\text{J/K})(293\,\text{K})}} = 3.27\times10^{28}\,\text{Hz}$$

$$\approx \boxed{3.27\times10^{28}\,\text{Hz}}$$

19. In the Maxwell distribution, Eq. 18-6, we see that the mass and temperature always occur as a ratio. Thus if the mass has been doubled, doubling the temperature will keep the velocity distribution constant.

20. (*a*) We find the average by adding the speed of every particle and then dividing by the number of particles.

$$\overline{v} = \frac{1}{N}\sum_i n_i v_i = \frac{1}{25}\left[\begin{array}{c}2(10\,\text{m/s}) + 7(15\,\text{m/s}) + 4(20\,\text{m/s}) + 3(25\,\text{m/s})\\ +6(30\,\text{m/s}) + 1(35\,\text{m/s}) + 2(40\,\text{m/s})\end{array}\right] = \boxed{23\,\text{m/s}}$$

(*b*) We find the rms speed by taking the square root of the average squared speed.

$$v_{\text{rms}} = \sqrt{\frac{1}{N}\sum_i n_i v_i^2} = \sqrt{\frac{1}{25}\left[\begin{array}{c}2(10\,\text{m/s})^2 + 7(15\,\text{m/s})^2 + 4(20\,\text{m/s})^2 + 3(25\,\text{m/s})^2\\ +6(30\,\text{m/s})^2 + 1(35\,\text{m/s})^2 + 2(40\,\text{m/s})^2\end{array}\right]}$$

$$= 24.56\,\text{m/s} \approx \boxed{25\,\text{m/s}}$$

(*c*) The most probable speed is that one that occurs most frequently, $\boxed{15\,\text{m/s}}$.

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21. (*a*) We find the rms speed by taking the square root of the average squared speed.

$$v_{\text{rms}} = \sqrt{\frac{1}{N}\sum_i n_i v_i^2} = \sqrt{\frac{1}{15,200}\begin{bmatrix}1600(220\,\text{m/s})^2 + 4100(440\,\text{m/s})^2 + 4700(660\,\text{m/s})^2 \\ +3100(880\,\text{m/s})^2 + 1300(1100\,\text{m/s})^2 + 400(1320\,\text{m/s})^2\end{bmatrix}}$$

$$= 706.6\,\text{m/s} \approx \boxed{710\,\text{m/s}}$$

(*b*) The temperature is related to the rms speed by Eq. 18-5.

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} \quad \rightarrow \quad T = \frac{mv_{\text{rms}}^2}{3k} = \frac{(2.00\times10^{-26}\,\text{kg})(706.6\,\text{m/s})^2}{3(1.38\times10^{-23}\,\text{J/K})} = 241.2\,\text{K} \approx \boxed{240\,\text{K}}$$

(*c*) Find the average speed, and then use a result from Example 18-5.

$$\overline{v} = \frac{1}{N}\sum_i n_i v_i = \frac{1}{15,200}\begin{bmatrix}1600(220\,\text{m/s}) + 4100(440\,\text{m/s}) + 4700(660\,\text{m/s}) \\ +3100(880\,\text{m/s}) + 1300(1100\,\text{m/s}) + 400(1320\,\text{m/s})\end{bmatrix}$$

$$= 654.2\,\text{m/s} \approx \boxed{650\,\text{m/s}}$$

$$\overline{v} = \sqrt{\frac{8}{\pi}\frac{kT}{m}} \quad \rightarrow \quad T = \frac{\pi m\overline{v}^2}{8k} = \frac{\pi(2.00\times10^{-26}\,\text{kg})(654.2\,\text{m/s})^2}{8(1.38\times10^{-23}\,\text{J/K})} = 243.6\,\text{K} \approx \boxed{240\,\text{K}}$$

Yes, the temperatures are consistent.

22. (*a*) Show that $\int_0^\infty f(v)\,dv = N$. We use a change of variable, and we make use of an integral from Appendix B-5; specifically, $\int_0^\infty x^2 e^{-ax^2}dx = \sqrt{\frac{\pi}{16a^3}}$.

$$\int_0^\infty f(v)\,dv = \int_0^\infty 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} v^2 e^{-\frac{1}{2}\frac{mv^2}{kT}}dv$$

$$x = \sqrt{\frac{mv^2}{2kT}} \quad \rightarrow \quad x^2 = \frac{mv^2}{2kT} \quad \rightarrow \quad v^2 = \frac{2kT}{m}x^2 \quad \rightarrow \quad v = \sqrt{\frac{2kT}{m}}x \quad \rightarrow \quad dv = \sqrt{\frac{2kT}{m}}dx$$

$$\int_0^\infty 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} v^2 e^{-\frac{1}{2}\frac{mv^2}{kT}}dv = \int_0^\infty 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2}\frac{2kT}{m}x^2 e^{-x^2}\sqrt{\frac{2kT}{m}}dx$$

$$= 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2}\frac{2kT}{m}\sqrt{\frac{2kT}{m}}\int_0^\infty x^2 e^{-x^2}dx = 4\pi N\left(\frac{1}{\pi}\right)^{3/2}\frac{\sqrt{\pi}}{4} = \boxed{N}$$

(*b*) Show that $\int_0^\infty v^2 f(v)\,dv \Big/ N = \frac{3kT}{m}$. We use the same change of variable as above, and we make use of an integral from Appendix B-5; specifically, $\int_0^\infty x^4 e^{-ax^2}dx = \frac{3}{8}\sqrt{\pi}$.

$$\int_0^\infty v^2 f(v)\,dv = \int_0^\infty 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} v^4 e^{-\frac{1}{2}\frac{mv^2}{kT}}dv$$

$$x = \sqrt{\frac{mv^2}{2kT}} \quad \rightarrow \quad x^2 = \frac{mv^2}{2kT} \quad \rightarrow \quad v^2 = \frac{2kT}{m}x^2 \quad \rightarrow \quad v = \sqrt{\frac{2kT}{m}}x \quad \rightarrow \quad dv = \sqrt{\frac{2kT}{m}}dx$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\int_0^\infty 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} v^4 e^{-\frac{1}{2}\frac{mv^2}{kT}}\,dv = \int_0^\infty 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} \frac{4k^2T^2}{m^2} x^4 e^{-x^2}\sqrt{\frac{2kT}{m}}\,dx$$

$$= 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} \frac{4k^2T^2}{m^2}\sqrt{\frac{2kT}{m}}\int_0^\infty x^4 e^{-x^2}\,dx = N\frac{3kT}{m} \quad \rightarrow$$

$$\int_0^\infty v^2 f(v)\,dv = N\frac{3kT}{m} \quad \rightarrow \quad \boxed{\int_0^\infty v^2 f(v)\,dv \Big/ N = \frac{3kT}{m}}$$

23. From Fig. 18-6, we see that CO_2 is a vapor at 30 atm and 30°C.

24. (*a*) From Fig. 18-6, at atmospheric pressure, CO_2 can exist as solid or vapor.
(*b*) From Fig. 18-6, for CO_2 to exist as a liquid, $5.11\text{ atm} \le P \le 73\text{ atm}$ and $-56.6^\circ\text{C} \le T \le 31^\circ\text{C}$.

25. (*a*) From Fig. 18-5, water is vapor when the pressure is 0.01 atm and the temperature is 90°C.
(*b*) From Fig. 18-5, water is solid when the pressure is 0.01 atm and the temperature is –20°C.

26. (*a*) At the initial conditions, the water is a liquid. As the pressure is lowered, it becomes a vapor at some pressure between 1.0 atm and 0.006 atm. It would still be a vapor at 0.004 atm.
(*b*) At the initial conditions, the water is a liquid. As the pressure is lowered, it becomes a solid at a pressure of 1.0 atm, and then becomes a vapor at some pressure lower than 0.006 atm. It would be a vapor at 0.004 atm.

27. From Table 18-2, the saturated vapor pressure at 30°C is 4240 Pa. Since the relative humidity is 85%, the partial pressure of water is as follows.

$$P_{\text{water}} = 0.85P_{\text{saturated}} = 0.85(4240\text{ Pa}) = \boxed{3600\text{ Pa}}$$

28. From Table 18-2, the saturated vapor pressure at 25°C is 3170 Pa. Since the relative humidity is 55%, the partial pressure of water is as follows.

$$P_{\text{water}} = 0.55P_{\text{saturated}} = 0.55(3170\text{ Pa}) = \boxed{1700\text{ Pa}}$$

29. At the boiling temperature, the external air pressure equals the saturated vapor pressure. Thus from Table 18-2, for 80°C the saturated air pressure is 355 torr or 4.73×10^4 Pa or 0.466 atm.

30. From Table 18-2, if the temperature is 25°C, the saturated vapor pressure is 23.8 torr. If the relative humidity is 75%, then the partial pressure of water is 75% of the saturated vapor pressure, or 17.85 torr. The dew point is the temperature at which the saturated vapor pressure is 17.85 torr, and from Table 18-2 that is between 20°C and 25°C. Since there is no entry for 17.85 torr, the temperature can be estimated by a linear interpolation. Between 20°C and 25°C, the temperature change per torr is as follows:

$$\frac{(25-20)^\circ\text{C}}{(23.8-17.5)\text{ torr}} = 0.7937^\circ\text{C}/\text{torr}\,.$$

Thus the temperature corresponding to 17.85 torr is

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$20°\text{C} + \left[(17.85 - 17.5)\,\text{torr}\right](0.7937\,\text{C°/torr}) = 20.28°\text{C} \approx \boxed{20°\text{C}}.$$

31. At the boiling temperature, the air pressure equals the saturated vapor pressure. The pressure of 0.75 atm is equal to 7.60×10^4 Pa. From Table 18-2, the temperature is between 90°C and 100°C. Since there is no entry for 7.60×10^4 Pa, the temperature can be estimated by a linear interpolation. Between 90°C and 100°C, the temperature change per Pa is as follows:

$$\frac{(100-90)\,\text{C}^\circ}{(10.1-7.01)\times10^4\,\text{Pa}} = 3.236\times10^{-4}\,\text{C}^\circ/\text{Pa}.$$

Thus the temperature corresponding to 7.60×10^4 Pa is

$$90°\text{C} + \left[(7.60-7.01)\times10^4\,\text{Pa}\right]\left(3.236\times10^{-4}\,\text{C}^\circ/\text{Pa}\right) = 91.9°\text{C} \approx \boxed{92°\text{C}}.$$

32. The volume, temperature, and pressure of the water vapor are known. We use the ideal gas law to calculate the mass. The pressure must be interpolated from Table 18-2. Between 20°C and 25°C, the pressure change per temperature change per C° is as follows.

$$\frac{(3170-2330)\,\text{Pa}}{(25-20)\,\text{C}^\circ} = 168\,\text{Pa/C}^\circ$$

Thus the saturated vapor pressure at 20°C is $2330\,\text{Pa} + \left(168\,\text{Pa/C}^\circ\right)4\text{C}^\circ = 3000\,\text{Pa}.$

$$PV = nRT \;\rightarrow\; n = \frac{PV}{RT} = \frac{(0.65)(3000\,\text{Pa})(5.0\,\text{m})(6.0\,\text{m})(2.4\,\text{m})}{(8.314\,\text{J/mol•K})(273.15\,\text{K}+24.0\,\text{K})} = 56.8\ \text{mol}$$

$$m_{\text{H}_2\text{O}} = (56.8\ \text{mol})(0.018\,\text{kg/mol}) = \boxed{1.0\,\text{kg}}$$

33. Since the water is boiling at 120°C, the saturated vapor pressure is the same as the pressure inside the pressure cooker. From Table 18-2, the pressure is $\boxed{1.99\times10^5\,\text{Pa} = 1.97\ \text{atm}}$.

34. The total amount of water vapor that can be in the air can be found from the saturated vapor pressure in Table 18-2, using the ideal gas law. At 25°C, that pressure is 3.17×10^3 Pa.

$$PV = nRT \;\rightarrow\; n = \frac{PV}{RT} = \frac{\left(3.17\times10^3\,\text{Pa}\right)\left(440\,\text{m}^3\right)}{(8.314\,\text{J/mol•K})(273+25)\,\text{K}} = 563\,\text{moles}$$

Since the relative humidity is only 65%, only 65% of the total possible water is in the air. Thus 35% of the total possible water can still evaporate into the air.

$$m_{\text{evaporate}} = 0.35(563\,\text{moles})\left(\frac{18\times10^{-3}\,\text{kg}}{1\ \text{mole}}\right) = \boxed{3.5\,\text{kg}}$$

35. For boiling to occur at 120°C, the pressure inside the cooker must be the saturated vapor pressure of water at that temperature. That value can be found in Table 18-2. For the mass to stay in place and contain the steam inside the cooker, the weight of the mass must be greater than the force exerted by the gauge pressure from the gas inside the cooker. The limiting case, to hold the temperature right at 120°C, would be with the mass equal to that force.

$$mg = F_{\substack{\text{gauge}\\\text{pressure}}} = \left(P_{\text{inside}} - P_{\text{atm}}\right)A = \left(P_{\text{inside}} - P_{\text{atm}}\right)\pi r^2 \;\rightarrow$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$m = \frac{(P_{\text{inside}} - P_{\text{atm}})\pi r^2}{g} = \frac{\left(1.99\times10^5\,\text{Pa} - 1.013\times10^5\,\text{Pa}\right)\pi\left(1.5\times10^{-3}\,\text{m}\right)^2}{9.80\,\text{m/s}^2} = 0.0705\,\text{kg}$$

$$\approx \boxed{70\,\text{g}}\ (2\text{ sig. fig.})$$

36. (*a*) The true atmospheric pressure will be greater than the reading from the barometer. In Figure 13-11, if there is a vapor pressure at the top of the tube, then $P_{\text{atm}} - \rho gh = P_{\text{vapor}}$. The reading from the barometer will be $\rho gh = P_{\text{atm}} - P_{\text{vapor}} < P_{\text{atm}}$.

(*b*) The percent error is found from the atmospheric pressure and the vapor pressure.

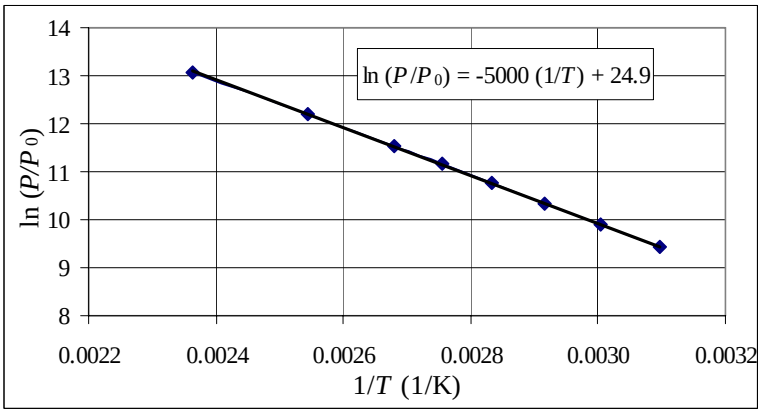
$$\%\text{ diff} = \left(\frac{\rho gh - P_{\text{atm}}}{P_{\text{atm}}}\right)\times100 = \left(-\frac{P_{\text{vapor}}}{P_{\text{atm}}}\right)\times100 = \left(-\frac{0.0015\,\text{mm-Hg}}{760\,\text{mm-Hg}}\right)\times100$$

$$= \boxed{\left(-2.0\times10^{-4}\right)\%}$$

(*c*) From Table 18-2, the saturated water vapor pressure at STP is 611 Pa.

$$\%\text{ diff} = \left(-\frac{P_{\text{vapor}}}{P_{\text{atm}}}\right)\times100 = \left(-\frac{611\,\text{Pa}}{1.013\times10^5\,\text{Pa}}\right)\times100 = \boxed{0.603\%}$$

37. At 30.0°C, the saturated vapor pressure as found in Table 18-2 is 4240 Pa. We can find the partial pressure of the water vapor by using the equation given immediately before Example 18-6.



$$\text{Rel. Hum.} = \frac{P_{\text{partial}}}{P_{\text{saturated}}}\times100 \quad\rightarrow\quad P_{\text{partial}} = P_{\text{saturated}}\frac{\text{Rel. Hum.}}{100} = (4240\,\text{Pa})(0.45) = 1908\,\text{Pa}$$

The dew point is that temperature at which 1908 Pa is the saturated vapor pressure. From Table 18-2, we see that will be between 15°C and 20°C.

$$T_{1920} = T_{1710} + \frac{1908\,\text{Pa} - 1710\,\text{Pa}}{2330\,\text{Pa} - 1710\,\text{Pa}}(5\text{C}^\circ) = \boxed{16.6^\circ\text{C}}$$

38. The outside air is at the dew point, and so its water vapor pressure is the saturated vapor pressure at 5.0°C, which comes from Table 18-2 and is 872 Pa. Consider a fixed number of moles that moves from outside to inside at constant pressure. Because the pressure is constant, the partial pressure of water vapor is 872 Pa inside as well. The saturated pressure at the higher temperature is 2300 Pa. So the relative humidity is $872\,\text{Pa}/2330\,\text{Pa} = 0.374 = \boxed{37.4\%}$.

39. (*a*) The plot is shown, with an accompanying linear fit. The slope of the line is $\boxed{-5000\,\text{K}}$, and the *y*-intercept is $\boxed{24.91}$. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH18.XLS," on tab "Problem 18.39a."

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The straight line results can be expressed as follows.

$$y = mx + b \;\rightarrow\; \ln\left(P/P_0\right) = m\left(\frac{1}{T}\right) + b \;\rightarrow\; P = P_0 e^{\frac{m}{T}+b} = P_0 e^b e^{\frac{m}{T}}$$

We define $B = P_0 e^b = (1\,\text{Pa})\,e^{24.91} = 6.58\times10^{10}\,\text{Pa} \approx 7\times10^{10}\,\text{Pa}$ and $A = -m = 5000\,\text{K}$. Then we have the following.

$$P = P_0 e^b e^{m/T} = \boxed{Be^{-A/T}} = \left(7\times10^{10}\,\text{Pa}\right)e^{-5000/T}$$

40. For one mole of gas, the "lost" volume (the volume occupied by the molecules) is the value of *b*. We assume spherical molecules.

$$b = N_0\,\tfrac{4}{3}\pi\left(\tfrac{1}{2}d\right)^3 \;\rightarrow$$

$$d = 2\left(\frac{3b}{4\pi N_0}\right)^{1/3} = 2\left(\frac{3\left(3.2\times10^{-5}\,\text{m}^3/\text{mol}\right)}{4\pi\left(6.02\times10^{23}\,\text{molecules/mol}\right)}\right)^{1/3} = \boxed{4.7\times10^{-10}\,\text{m}}$$

41. (*a*) Use the van der Waals equation.

$$P = \frac{RT}{(V/n)-b} - \frac{a}{(V/n)^2}$$

$$= \frac{(8.314\,\text{J/mol•K})(273\,\text{K})}{\left(0.70\times10^{-3}\,\text{m}^3/\text{mol}\right)-\left(3.2\times10^{-5}\,\text{m}^3/\text{mol}\right)} - \frac{0.13\,\text{m/s}}{\left(0.70\times10^{-3}\,\text{m}^3/\text{mol}\right)^2} = \boxed{3.1\times10^6\,\text{Pa}}$$

(*b*) Use the ideal gas law.

$$PV = nRT \;\rightarrow\; P = \frac{nRT}{V} = \frac{(1.0\,\text{mol})(8.314\,\text{J/mol•K})(273\,\text{K})}{0.70\times10^{-3}\,\text{m}^3} = \boxed{3.2\times10^6\,\text{Pa}}$$

42. The van der Waals pressure can be either higher or lower than the ideal gas pressure, depending on the volume. Accordingly, we use a parameter "*c*," which is the ratio of the van der Waals pressure to the ideal pressure.

$$P_V = cP_I \;\rightarrow\; \frac{RT}{(V/n)-b} - \frac{a}{(V/n)^2} = c\frac{nRT}{V} \;\rightarrow\; RT(c-1)V^2 + (an - bcnRT)V - ban^2 = 0 \;\rightarrow$$

$$V = \frac{-(an-bcnRT) \pm n\sqrt{(a-bcRT)^2 + 4RT(c-1)ba}}{2RT(c-1)}$$

$$RT(c-1)V^2 + (an-bcnRT)V - ban^2 = 0$$

For $c = 0.95$, the van der Waals pressure being lower than the ideal gas pressure, we get volumes of $\boxed{4.16\times10^{-5}\,\text{m}^3}$ and $\boxed{2.16\times10^{-4}\,\text{m}^3}$. For $c = 1.05$, the van der Waals pressure being higher than the ideal gas pressure, we get a volume of $\boxed{3.46\times10^{-5}\,\text{m}^3}$. Note that the pressures are equal for a volume of $3.72\times10^{-5}\,\text{m}^3$.

43. (*a*) The Van der Waals equation of state is given by Eq. 18-9, $P = \dfrac{RT}{(V/n)-b} - \dfrac{a}{(V/n)^2}$. At the critical point, both the first and second derivatives of P with respect to V are 0. Use those conditions to find the critical volume, and then evaluate the critical temperature and critical pressure.

$$P = \frac{RT}{(V/n)-b} - \frac{a}{(V/n)^2} = \frac{nRT}{V-nb} - \frac{an^2}{V^2}$$

$$\frac{dP}{dV} = -\frac{nRT}{(V-nb)^2} + \frac{2an^2}{V^3} \quad ; \quad \frac{dP}{dV} = 0 \quad \rightarrow \quad T_{\text{crit}} = \frac{2an(V_{\text{crit}}-nb)^2}{RV_{\text{crit}}^3}$$

$$\frac{d^2P}{dV^2} = \frac{2nRT}{(V-nb)^3} - \frac{6an^2}{V^4} \quad ; \quad \frac{d^2P}{dV^2} = 0 \quad \rightarrow \quad T_{\text{crit}} = \frac{3an(V_{\text{crit}}-nb)^3}{RV_{\text{crit}}^4}$$

Set the two expressions for the critical temperature equal to each other, and solve for the critical volume. Then use that expression to find the critical temperature, and finally the critical pressure.

$$\frac{2an(V_{\text{crit}}-nb)^2}{RV_{\text{crit}}^3} = \frac{3an(V_{\text{crit}}-nb)^3}{RV_{\text{crit}}^4} \quad \rightarrow \quad V_{\text{crit}} = 3nb$$

$$T_{\text{crit}} = \frac{2an(V_{\text{crit}}-nb)^2}{RV_{\text{crit}}^3} = \frac{2an(3nb-nb)^2}{R(3nb)^3} = \boxed{\frac{8a}{27bR}}$$

$$P_{\text{crit}} = \frac{nRT_{\text{crit}}}{V_{\text{crit}}-nb} - \frac{an^2}{V_{\text{crit}}^2} = \boxed{\frac{a}{27b^2}}$$

(*b*) To evaluate the constants, use the ratios $\dfrac{T_{\text{crit}}^2}{P_{\text{crit}}}$ and $\dfrac{T_{\text{crit}}}{P_{\text{crit}}}$.

$$\frac{T_{\text{crit}}^2}{P_{\text{crit}}} = \frac{\left(\dfrac{8a}{27bR}\right)^2}{\dfrac{a}{27b^2}} = \frac{64a}{27R^2} \quad \rightarrow$$

$$a = \frac{27R^2T_{\text{crit}}^2}{64P_{\text{crit}}} = \frac{27\left(8.314\dfrac{\text{J}}{\text{mol}\cdot\text{K}}\right)^2(304\,\text{K})^2}{64(72.8)(1.013\times10^5\,\text{Pa})} = \boxed{0.365\frac{\text{N}\cdot\text{m}^4}{\text{mol}^2}}$$

$$\frac{T_{\text{crit}}}{P_{\text{crit}}} = \frac{\dfrac{8a}{27bR}}{\dfrac{a}{27b^2}} = \frac{8b}{R} \quad \rightarrow \quad b = \frac{RT_{\text{crit}}}{8P_{\text{crit}}} = \frac{\left(8.314\dfrac{\text{J}}{\text{mol}\cdot\text{K}}\right)(304\,\text{K})}{8(72.8)(1.013\times10^5\,\text{Pa})} = \boxed{4.28\times10^{-5}\,\text{m}^3/\text{mol}}$$

44. (*a*) We use the ideal gas law as applied to the air before it was put into the tank.

$$PV = nRT \quad \rightarrow \quad n = \frac{(1.013\times10^5\,\text{Pa})(2.3\,\text{m}^3)}{(8.314\,\text{J/mol}\cdot\text{K})(293\,\text{K})} = 95.64\,\text{mol} \approx \boxed{96\,\text{mol}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Use the ideal gas law.

$$PV = nRT \quad \rightarrow$$

$$P = \frac{nRT}{V} = \frac{(96\,\text{mol})(8.314\,\text{J/mol•K})(293\,\text{K})}{(0.012\,\text{m}^3)} = 1.9488\times10^7\,\text{Pa} \approx \boxed{1.9\times10^7\,\text{Pa}} \approx 190\,\text{atm}$$

(*c*) Use the van der Waals equation.

$$P = \frac{RT}{(V/n)-b} - \frac{a}{(V/n)^2} = \frac{nRT}{V-nb} - \frac{an^2}{V^2}$$

$$= \frac{(96\,\text{mol})(8.314\,\text{J/mol•K})(293\,\text{K})}{(0.012\,\text{m}^3)-(96\,\text{mol})(3.72\times10^{-5}\,\text{m}^3/\text{mol})} - \frac{(0.1373\,\text{N•m}^4/\text{mol}^2)(96\,\text{mol})^2}{(0.012\,\text{m}^3)^2}$$

$$= 1.8958\times10^7\,\text{Pa} \approx \boxed{1.9\times10^7\,\text{Pa}}$$

(*d*) $$\%\,\text{error} = \left(\frac{P_{\text{ideal}} - P_{\substack{\text{van der}\\\text{Waals}}}}{P_{\substack{\text{van der}\\\text{Waals}}}}\right)\times100 = \left(\frac{1.9488\times10^7\,\text{Pa} - 1.8958\times10^7\,\text{Pa}}{1.8958\times10^7\,\text{Pa}}\right)\times100 = 2.796\% \approx \boxed{3\%}$$

45. The mean free path is given by Eq. 18-10b. Combine this with the ideal gas law to find the mean free path–pressure relationship.

$$PV = NkT \quad \rightarrow \quad \frac{N}{V} = \frac{P}{kT} \;;\; \ell_{\text{M}} = \frac{1}{4\pi\sqrt{2}r^2(N/V)} = \frac{kT}{4\pi\sqrt{2}r^2P} \quad \rightarrow \quad P = \frac{kT}{4\pi\sqrt{2}r^2\ell_{\text{M}}}$$

(*a*) $$P = \frac{kT}{4\pi\sqrt{2}r^2\ell_{\text{M}}} = \frac{(1.38\times10^{-23}\,\text{J/K})(293\,\text{K})}{4\pi\sqrt{2}(1.5\times10^{-10}\,\text{m})^2(0.10\,\text{m})} = \boxed{0.10\,\text{Pa}}$$

(*b*) $$P = \frac{kT}{4\pi\sqrt{2}r^2\ell_{\text{M}}} = \frac{(1.38\times10^{-23}\,\text{J/K})(293\,\text{K})}{4\pi\sqrt{2}(1.5\times10^{-10}\,\text{m})^2(3\times10^{-10}\,\text{m})} = \boxed{3\times10^7\,\text{Pa}} \approx 300\,\text{atm}$$

46. We want the mean free path to be 1.0 m. Use Eq. 18-10b with the ideal gas law.

$$PV = NkT \quad \rightarrow \quad \frac{N}{V} = \frac{P}{kT} \;;\; \ell_{\text{M}} = \frac{1}{4\pi\sqrt{2}r^2(N/V)} = \frac{kT}{4\pi\sqrt{2}r^2P} \quad \rightarrow$$

$$P = \frac{kT}{4\pi\sqrt{2}r^2\ell_{\text{M}}} = \frac{(1.38\times10^{-23}\,\text{J/K})(293\,\text{K})}{4\pi\sqrt{2}(1.5\times10^{-10}\,\text{m})^2(1.0\,\text{m})} = \boxed{0.010\,\text{Pa}}$$

47. First, we compare the rms speed of the hydrogen to the rms speed of the air, by Eq. 18-5.

$$\frac{(v_{\text{rms}})_{\text{H}_2}}{(v_{\text{rms}})_{\text{air}}} = \frac{\sqrt{3kT/m_{\text{H}_2}}}{\sqrt{kT/m_{\text{air}}}} = \sqrt{\frac{m_{\text{air}}}{m_{\text{H}_2}}} = \sqrt{\frac{29}{2}} = 3.8$$

Since the hydrogen is moving about 4 times faster than the air, we will use a stationary target approximation. We also assume that the inter-molecular distance for a collision would be the sum of the radii of the hydrogen and air molecules. The size of the air molecules are given in problem 45, and based on problem 71, we assume that the radius of the hydrogen molecule is the same as the diameter of the hydrogen atom. We use these assumptions to calculate the mean free path, similar to Eq. 18-10a. Use the ideal gas law.

$$PV = NkT \quad \rightarrow \quad \frac{N}{V} = \frac{P}{kT} \; ;$$

$$\ell_{\text{M}} = \frac{1}{\pi\left(r_{\text{H}_2} + r_{\text{air}}\right)^2 (N/V)} = \frac{kT}{\pi r^2 P} = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)(288\,\text{K})}{\pi\left[(1.0+1.5)\times10^{-10}\,\text{m}\right]^2\left(1.013\times10^{5}\,\text{Pa}\right)}$$

$$= 1.998\times10^{-7}\,\text{m} \approx \boxed{2\times10^{-7}\,\text{m}}$$

48. The mean free path is given by Eq. 18-10b. Combine this with the ideal gas law to find the mean free path–diameter relationship.

$$PV = NkT \quad \rightarrow \quad \frac{N}{V} = \frac{P}{kT} \; ; \; \ell_{\text{M}} = \frac{1}{4\pi\sqrt{2}r^2 (N/V)} = \frac{kT}{4\pi\sqrt{2}\left(\tfrac{1}{2}d\right)^2 P} \quad \rightarrow \quad d = \sqrt{\frac{kT}{\sqrt{2}\pi\ell_{\text{M}}P}}$$

(*a*) $$d = \sqrt{\frac{kT}{\sqrt{2}\pi\ell_{\text{M}}P}} = \sqrt{\frac{\left(1.38\times10^{-23}\,\text{J/K}\right)(273\,\text{K})}{\sqrt{2}\pi\left(5.6\times10^{-8}\,\text{m}\right)\left(1.013\times10^{5}\,\text{Pa}\right)}} = \boxed{3.9\times10^{-10}\,\text{m}}$$

(*b*) $$d = \sqrt{\frac{kT}{\sqrt{2}\pi\ell_{\text{M}}P}} = \sqrt{\frac{\left(1.38\times10^{-23}\,\text{J/K}\right)(273\,\text{K})}{\sqrt{2}\pi\left(25\times10^{-8}\,\text{m}\right)\left(1.013\times10^{5}\,\text{Pa}\right)}} = \boxed{1.8\times10^{-10}\,\text{m}}$$

49. (*a*) If the average speed of a molecule is $\overline{v}$, then the average time between collisions (seconds per collision) is the mean free path divided by the average speed. The reciprocal of that average time (collisions per second) is the frequency of collisions. Use Eq. 18-10b for the mean free path. The typical size of an air molecule is given in problem 45, which can be used for the size of the nitrogen molecule.

$$\Delta t_{\text{avg}} = \frac{\ell_{\text{M}}}{\overline{v}} \quad \rightarrow \quad f = \frac{1}{\Delta t_{\text{avg}}} = \frac{\overline{v}}{\ell_{\text{M}}} = \boxed{4\sqrt{2}\pi r^2 \overline{v}\,\frac{N}{V}}$$

(*b*) From Eq. 18-7b, $\overline{v} = \sqrt{\dfrac{8kT}{\pi m}}$, and from the ideal gas law, $PV = NkT \quad \rightarrow \quad \dfrac{N}{V} = \dfrac{P}{kT}$. Use these relationships to calculate the collision frequency.

$$f = 4\sqrt{2}\pi r^2 \overline{v}\,\frac{N}{V} = 4\sqrt{2}\pi r^2 \sqrt{\frac{8kT}{\pi m}}\,\frac{P}{kT} = 16Pr^2\sqrt{\frac{\pi}{mkT}}$$

$$= 16(0.010)\left(1.013\times10^{5}\,\text{Pa}\right)\left(1.5\times10^{-10}\,\text{m}\right)^2 \times$$

$$\sqrt{\frac{\pi}{28\left(1.66\times10^{-27}\,\text{kg}\right)\left(1.38\times10^{-23}\,\text{J/K}\right)(293\,\text{K})}} = \boxed{4.7\times10^{7}\ \text{collisions/s}}$$

50. The collision frequency is derived in problem 49 as $f = 16Pr^2\sqrt{\dfrac{\pi}{mkT}}$. Only one significant figure was given for the mean free path, so only one significant figure should be in the answer.

$$f = 16Pr^2\sqrt{\frac{\pi}{mkT}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= 16\left(1.013\times10^{5}\,\text{Pa}\right)\left(1.5\times10^{-10}\,\text{m}\right)^{2}\sqrt{\frac{\pi}{29\left(1.66\times10^{-27}\,\text{kg}\right)\left(1.38\times10^{-23}\,\text{J/K}\right)\left(273\,\text{K}\right)}}$$

$$= 4.8\times10^{9}\,\text{Hz} \approx \boxed{5\times10^{9}\,\text{Hz}}$$

51. Use the ideal gas law to evaluate the mean free path. Then compare the mean free path to the dimensions of the box in order to estimate the collision ratio. The size of air molecules is given in problem 45. The number of collisions per second is the reciprocal of the average time between collisions.

$$PV = NkT \quad\rightarrow\quad \frac{N}{V} = \frac{P}{kT}\ ;$$

$$\ell_{\text{M}} = \frac{1}{4\pi\sqrt{2}r^{2}\left(N/V\right)} = \frac{kT}{4\pi\sqrt{2}r^{2}P} = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)\left(273\,\text{K}\right)}{4\pi\sqrt{2}\left(1.5\times10^{-10}\,\text{m}\right)^{2}\left(1\times10^{-6}\,\text{torr}\right)\left(\frac{133\,\text{Pa}}{1\,\text{torr}}\right)} = 70.8\,\text{m}$$

$$\overline{v} = \frac{\ell_{\text{M}}}{t_{\substack{\text{molecular}\\\text{collisions}}}} = \frac{\ell_{\text{box}}}{t_{\substack{\text{wall}\\\text{collisions}}}} \quad\rightarrow\quad \frac{N_{\substack{\text{wall}\\\text{collisions}}}}{N_{\substack{\text{molecular}\\\text{collisions}}}} = \frac{t_{\substack{\text{molecular}\\\text{collisions}}}}{t_{\text{wall}}} = \frac{\ell_{\text{M}}}{\ell_{\text{box}}} = \frac{70.8\,\text{m}}{1.80\,\text{m}} = 39.3$$

The wall collisions are about 40 times more frequent than the inter-molecular collisions. So the particles make about $\boxed{1/40}$ of a collision with each other for each collision with a wall.

52. We estimate that only 2% of the electrons will have a collision in 32 cm or less, and so approximate that 2% of the electrons will have a collision in every 32 cm length. Thus 50% of the electrons should have a collision in a length of 25 times 32 cm, which is 8.00 m. So we want the mean free path to be 8.00 m. We also assume that the electrons are moving much faster than the air molecules, so that we model the air molecules as stationary. Finally, a collision will occur if an electron comes within a distance of r from a gas molecule (the radius of the gas molecule), not $2r$ as in the derivation in section 18-6. Combine this with the ideal gas law. We assume room temperature.

$$PV = NkT \quad\rightarrow\quad \frac{N}{V} = \frac{P}{kT}\ ;\ \ell_{\text{M}} = \frac{1}{\pi r^{2}\left(N/V\right)} = \frac{kT}{\pi r^{2}P} \quad\rightarrow$$

$$P = \frac{kT}{\pi r^{2}\ell_{\text{M}}} = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)\left(300\,\text{K}\right)}{\pi\left(1.5\times10^{-10}\,\text{m}\right)^{2}\left(8.00\,\text{m}\right)} = \boxed{7.3\times10^{-3}\,\text{Pa}} \approx 7\times10^{-6}\,\text{atm}$$

53. We use the equation derived in Eq. 18-9.

$$t = \frac{\overline{C}}{\Delta C}\frac{\left(\Delta x\right)^{2}}{D} = \frac{1}{2}\frac{\left(1.0\,\text{m}\right)^{2}}{\left(4\times10^{-5}\,\text{m}^{2}/\text{s}\right)} = 12{,}500\,\text{s} \approx \boxed{3.5\,\text{h}}$$

Because this time is so long, we see that convection is much more important than diffusion.

54. From Example 18-9, we have an expression for the time to diffuse a given distance. Divide the distance by the time to get the average speed.

$$t = \frac{\overline{C}}{\Delta C}\frac{\left(\Delta x\right)^{2}}{D} = \frac{\frac{1}{2}\left(1.00+0.50\right)\text{mol/m}^{3}}{\left(1.00-0.50\right)\text{mol/m}^{3}}\frac{\left(15\times10^{-6}\,\text{m}\right)^{2}}{\left(95\times10^{-11}\,\text{m}^{2}/\text{s}\right)} = 0.3553\,\text{s} \approx \boxed{0.36\,\text{s}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$v_{\text{diffuse}} = \frac{\Delta x}{t} = \frac{15\times10^{-6}\,\text{m}}{0.3553\,\text{s}} = \boxed{4.2\times10^{-5}\,\text{m/s}}$$

The rms thermal speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$.

$$v_{\text{rms}} = \sqrt{3kT/m} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)(293\,\text{K})}{75\left(1.66\times10^{-27}\,\text{kg}\right)}} = \boxed{3.1\times10^{2}\,\text{m/s}}$$

$$\frac{v_{\text{diffuse}}}{v_{\text{rms}}} = \frac{4.2\times10^{-5}\,\text{m/s}}{3.1\times10^{2}\,\text{m/s}} = 1.4\times10^{-7}$$

The diffusion speed is about seven orders of magnitude smaller than the thermal speed.

55. (*a*) Use the ideal gas law to find the concentration of the oxygen. We assume that the air pressure is 1.00 atm, and so the pressure caused by the oxygen is 0.21 atm.

$$PV = nRT \quad \rightarrow$$

$$\frac{n}{V} = \frac{P}{RT} = \frac{(0.21\,\text{atm})\left(1.013\times10^{5}\,\text{Pa/atm}\right)}{(8.315\,\text{J/mol•K})(293\,\text{K})} = 8.732\,\text{mol/m}^3 \approx \boxed{8.7\,\text{mol/m}^3}$$

(*b*) Use Eq. 18-11 to calculate the diffusion rate.

$$J = DA\frac{dC}{dx} \approx DA\frac{C_1 - C_2}{\Delta x} = \left(1\times10^{-5}\,\text{m}^2/\text{s}\right)\left(2\times10^{-9}\,\text{m}^2\right)\left(\frac{8.732\,\text{mol/m}^3 - 4.366\,\text{mol/m}^3}{2\times10^{-3}\,\text{m}}\right)$$

$$= 4.366\times10^{-11}\,\text{mol/s} \approx \boxed{4\times10^{-11}\,\text{mol/s}}$$

(*c*) From Example 18-9, we have an expression for the time to diffuse a given distance.

$$t = \frac{\bar{C}}{\Delta C}\frac{(\Delta x)^2}{D} = \frac{\frac{1}{2}\left(8.732\,\text{mol/m}^3 + 4.366\,\text{mol/m}^3\right)}{\left(8.732\,\text{mol/m}^3 - 4.366\,\text{mol/m}^3\right)}\frac{\left(2\times10^{-3}\,\text{m}\right)^2}{1\times10^{-5}\,\text{m}^2/\text{s}} = \boxed{0.6\,\text{s}}$$

56. We use the ideal gas law to find the length.

$$PV = P\ell^3 = NkT \quad \rightarrow \quad \ell = \left(\frac{NkT}{P}\right)^{1/3} = \left[\frac{\left(1\times10^{6}\right)\left(1.38\times10^{-23}\,\text{J/K}\right)(273\,\text{K})}{\left(1.013\times10^{5}\,\text{Pa}\right)}\right]^{1/3} = \boxed{3\times10^{-7}\,\text{m}}$$

57. The rms speed is given by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$. Hydrogen atoms have a mass of 1 atomic mass unit.

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)(2.7\,\text{K})}{1\left(1.66\times10^{-27}\,\text{kg}\right)}} = \boxed{260\,\text{m/s}}$$

The pressure is found from the ideal gas law, $PV = NkT$.

$$PV = NkT \quad \rightarrow \quad P = \frac{NkT}{V} = \frac{(1)\left(1.38\times10^{-23}\,\text{J/K}\right)(2.7\,\text{K})}{1\,\text{cm}^3\left(\frac{1\times10^{-6}\,\text{m}^3}{1\,\text{cm}^3}\right)} = 3.726\times10^{-17}\,\text{Pa}\left(\frac{1\,\text{atm}}{1.01\times10^{5}\,\text{Pa}}\right)$$

$$= 3.689\times10^{-22}\,\text{atm} \approx \boxed{3.7\times10^{-22}\,\text{atm}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

58. We assume that each molecule will have an average kinetic energy of $\frac{3}{2}kT$. Find the total number of molecules from the mass of the bacterium.

$$N = N_{\text{H}_2\text{O}} + N_{\text{other}}$$

$$= 0.70\left(2.0\times10^{-15}\,\text{kg}\right)\left(\frac{1\,\text{u}}{1.66\times10^{-27}\,\text{kg}}\right)\left(\frac{1\,\text{molecule}}{18\,\text{u}}\right)$$

$$+ 0.30\left(2.0\times10^{-15}\,\text{kg}\right)\left(\frac{1\,\text{u}}{1.66\times10^{-27}\,\text{kg}}\right)\left(\frac{1\,\text{molecule}}{10^5\,\text{u}}\right)$$

$$= \left(2.0\times10^{-15}\,\text{kg}\right)\left(\frac{1\,\text{u}}{1.66\times10^{-27}\,\text{kg}}\right)\left[0.70\left(\frac{1\,\text{molecule}}{18\,\text{u}}\right) + 0.30\left(\frac{1\,\text{molecule}}{10^5\,\text{u}}\right)\right]$$

$$= 4.69\times10^{10}\,\text{molecules}$$

$$K = N\left(\tfrac{3}{2}kT\right) = \left(4.69\times10^{10}\,\text{molecules}\right)\tfrac{3}{2}\left(1.38\times10^{-23}\,\text{J/K}\right)\left(310\,\text{K}\right) = \boxed{3\times10^{-10}\,\text{J}}$$

59. The rms speed is given by Eq. 18-5.

(*a*) $$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(310\,\text{K}\right)}{\left(89\,\text{u}\right)\left(1.66\times10^{-27}\,\text{kg/u}\right)}} = 294.7\,\text{m/s} \approx \boxed{290\,\text{m/s}}$$

(*b*) $$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(310\,\text{K}\right)}{\left(8.5\times10^{4}\,\text{u}\right)\left(1.66\times10^{-27}\,\text{kg/u}\right)}} = 9.537\,\text{m/s} \approx \boxed{9.5\,\text{m/s}}$$

60. The mean (average) speed is given in E. 18-7b, $\bar{v} = \sqrt{\frac{8}{\pi}\frac{kT}{m}}$. Using the escape velocity as $\bar{v}$, solve for the temperature.

(*a*) For oxygen molecules: $$T = \frac{\pi m\bar{v}^2}{8k} = \frac{\pi\left(32.0\right)\left(1.66\times10^{-27}\,\text{kg}\right)\left(1.12\times10^{4}\,\text{m/s}\right)^2}{8\left(1.38\times10^{-23}\,\text{J/K}\right)} = \boxed{1.90\times10^{5}\,\text{K}}$$

(*b*) For helium atoms: $$T = \frac{\pi m\bar{v}^2}{8k} = \frac{\pi\left(4.00\right)\left(1.66\times10^{-27}\,\text{kg}\right)\left(1.12\times10^{4}\,\text{m/s}\right)^2}{8\left(1.38\times10^{-23}\,\text{J/K}\right)} = \boxed{2.37\times10^{4}\,\text{K}}$$

(*c*) Because the "escape temperature" is so high for oxygen, very few oxygen molecules ever escape the atmosphere. But helium, with one-eighth the mass, can escape at a much lower temperature. While the temperature of the Earth is not close to $2.37\times10^{4}\,\text{K}$ today, during the Earth's formation its temperature was possibly much hotter — presumably hot enough that helium was able to escape the atmosphere.

61. Calculate the volume per molecule from the ideal gas law, and assume the molecular volume is spherical.

$$PV = NkT \quad\rightarrow\quad \frac{V}{N} = \frac{kT}{P} = \tfrac{4}{3}\pi r^3 \quad\rightarrow$$

$$r_{\text{volume}} = \left(\frac{3kT}{4\pi P}\right)^{1/3} = \left(\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(273\,\text{K}\right)}{4\pi\left(1.01\times10^{5}\,\text{Pa}\right)}\right)^{1/3} = 2.07\times10^{-9}\,\text{m}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The intermolecular distance would be twice this "radius," so about $4\times10^{-9}\,\text{m}$. This is about 130 times larger than the molecular diameter: $\dfrac{d_{\text{volume}}}{d_{\text{molecule}}} \approx \dfrac{4\times10^{-9}\,\text{m}}{3\times10^{-10}\,\text{m}} = 13.3$. So if we say the molecular diameter is 4 cm, then the intermolecular distance would be 13.3 times that, or about $\boxed{50\text{ cm}}$.

62. (*a*) The mean speed is given by Eq. 18-7b. The atomic weight of cesium is 133.

$$\overline{v} = \sqrt{\frac{8kT}{\pi m}} = \sqrt{\frac{8\left(1.38\times10^{-23}\,\text{J/K}\right)\left(673\,\text{K}\right)}{\pi\left(133\right)\left(1.66\times10^{-27}\,\text{kg}\right)}} = 327.3\,\text{m/s} \approx \boxed{330\,\text{m/s}}$$

(*b*) The collision frequency is the mean speed divided by the mean free path as given by Eq. 18-10b. We also use the ideal gas law.

$$PV = NkT \quad\rightarrow\quad \frac{N}{V} = \frac{P}{kT}\ ;$$

$$\ell_{\text{M}} = \frac{1}{4\pi\sqrt{2}r^2\left(N/V\right)} = \frac{kT}{4\pi\sqrt{2}r^2P} = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)\left(673\,\text{K}\right)}{4\pi\sqrt{2}\left(1.65\times10^{-10}\,\text{m}\right)^2\left(17\,\text{mm-Hg}\right)\left(\dfrac{133\,\text{Pa}}{1\,\text{mm-Hg}}\right)}$$

$$= 8.49\times10^{-6}\,\text{m}$$

$$f = \frac{\overline{v}}{\ell_{\text{M}}} = \frac{327.3\,\text{m/s}}{8.49\times10^{-6}\,\text{m}} = 3.855\times10^{7}\ \text{collisions/s} \approx \boxed{3.9\times10^{7}\ \text{collisions/s}}$$

(*c*) The total number of collisions per second in the gas is the number of collisions per second for a single atom times half the number of atoms in the gas, because each collision involves 2 of the gas atoms.

$$f_{\text{total}} = \tfrac{1}{2}Nf_{\text{single}} = \frac{PV}{2kT}\,f_{\text{single}}$$

$$= \frac{\left(17\,\text{mm-Hg}\right)\left(\dfrac{133\,\text{Pa}}{1\,\text{mm-Hg}}\right)\left(55\,\text{cm}^3\right)\left(\dfrac{1\,\text{m}^3}{10^6\,\text{cm}^3}\right)}{2\left(1.38\times10^{-23}\,\text{J/K}\right)\left(673\,\text{K}\right)}\left(3.855\times10^{7}\ \text{collisions/s}\right)$$

$$= \boxed{2.6\times10^{26}\ \text{collisions/s}}$$

63. The gravitational potential energy is given by $U = mgh$, and the average kinetic energy is $K = \tfrac{1}{2}mv_{\text{rms}}^2 = \tfrac{3}{2}kT$. We find the ratio of potential energy to kinetic energy. The molecular mass of oxygen molecules is 32 u.

$$\frac{U}{K} = \frac{mgh}{\frac{3}{2}kT} = \frac{\left(32.0\right)\left(1.66\times10^{-27}\,\text{kg}\right)\left(9.80\,\text{m/s}^2\right)\left(1.00\,\text{m}\right)}{\frac{3}{2}\left(1.38\times10^{-23}\,\text{J/K}\right)\left(293\,\text{K}\right)} = \boxed{8.58\times10^{-5}}$$

$\boxed{\text{Yes}}$, it is reasonable to neglect the gravitational potential energy.

64. Assume that the water vapor behaves like an ideal gas. At 20°C, the saturated vapor pressure is $2.33\times10^{3}\,\text{Pa}$. Using the ideal gas law, find the number of moles of water in the air at both 95% and 40%. Subtract those mole amounts to find the amount of water that must be removed.

$$PV = nRT \quad\rightarrow\quad n = \frac{PV}{RT} \quad\rightarrow$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$n_1 - n_2 = \frac{V}{RT}(P_1 - P_2) = \frac{(115\,\text{m}^2)(2.8\,\text{m})}{(8.314\,\text{J/mol•k})(293\,\text{K})}(2.33\times10^3\,\text{Pa})(0.95-0.40) = 169.4\ \text{mol}$$

$$169.4\,\text{mol}\left(\frac{18\times10^{-3}\,\text{kg}}{1\,\text{mol}}\right) = \boxed{3.0\,\text{kg}}$$

65. Find the volume "allotted" per molecule in the ideal gas law for a room at 1 atm and 23°C, and compare this to the volume of an actual molecule, modeled by a cubical volume.

$$PV = NkT \ \rightarrow\ V_{\text{allotted}} = \frac{V}{N} = \frac{kT}{P}\ ;\ V_{\text{molecule}} \approx d^3$$

$$\frac{V_{\text{molecule}}}{V_{\text{allotted}}} = \frac{d^3}{\frac{kT}{P}} = \frac{Pd^3}{kT} = \frac{(1.013\times10^5\,\text{Pa})(0.3\times10^{-9}\,\text{m})^3}{(1.38\times10^{-23}\,\text{J/K})(300\,\text{K})} = 6.6\times10^{-4} = (6.6\times10^{-2})\,\% \approx \boxed{0.07\%}$$

66. (*a*) The volume of each gas is half of the tank volume. Use the ideal gas law, with a pressure of 13 atm, to find the number of molecules.

$$PV = NkT \ \rightarrow\ N = \frac{PV}{kT} = \frac{13(1.013\times10^5\,\text{Pa})\frac{1}{2}(3.1\times10^{-3}\,\text{m}^3)}{(1.38\times10^{-23}\,\text{J/K})(293\,\text{K})} = 5.048\times10^{23}\,\text{molecules}$$

$$\approx \boxed{5.0\times10^{23}\,\text{molecules}}$$

Both gases have the same number of molecules. The identity of the gas does not enter into the ideal gas law.

(*b*) The average kinetic energy of a molecule is $\frac{3}{2}kT$. Since both gases are the same temperature, the ratio of the average kinetic energies is $\boxed{1:1}$.

(*c*) The average kinetic energy of a molecule is also given by $\frac{1}{2}mv_{\text{rms}}^2$. Use this to find the ratio of the rms speeds.

$$\left(\tfrac{1}{2}mv_{\text{rms}}^2\right)_{\text{He}} = \left(\tfrac{1}{2}mv_{\text{rms}}^2\right)_{\text{O}_2} = \tfrac{3}{2}kT \ \rightarrow\ \frac{(v_{\text{rms}})_{\text{He}}}{(v_{\text{rms}})_{\text{O}_2}} = \sqrt{\frac{m_{\text{O}_2}}{m_{\text{He}}}} = \sqrt{\frac{32}{4}} = \sqrt{8} = \boxed{2.8}$$

67. The temperature can be found from the rms speed by Eq. 18-5, $v_{\text{rms}} = \sqrt{3kT/m}$. The molecular mass of nitrogen molecules is 28.

$$v_{\text{rms}} = \sqrt{3kT/m} \ \rightarrow$$

$$T = \frac{mv_{\text{rms}}^2}{3k} = \frac{(28)(1.66\times10^{-27}\,\text{kg})\left[(4.2\times10^4\,\text{km/h})\left(\frac{1\,\text{m/s}}{3.6\,\text{km/h}}\right)\right]^2}{3(1.38\times10^{-23}\,\text{J/K})} = \boxed{1.5\times10^5\,\text{K}}$$

68. We assume that the energy required to evaporate the water is the kinetic energy of the evaporating molecules. The rms speed is given by Eq. 18-5.

$$E_{\text{evap}} = \tfrac{1}{2}m_{\text{evap}}v_{\text{evap}}^2 \ \rightarrow\ v_{\text{evap}} = \sqrt{\frac{2E_{\text{evap}}}{m_{\text{evap}}}} = \sqrt{\frac{2(2450\,\text{J})}{(1.00\times10^{-3}\,\text{kg})}} = \boxed{2210\,\text{m/s}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(293\,\text{K}\right)}{18.0\left(1.66\times10^{-27}\,\text{kg}\right)}} = 637\,\text{m/s} \quad \rightarrow \quad \frac{v_{\text{evap}}}{v_{\text{rms}}} = \frac{2210\,\text{m/s}}{637\,\text{m/s}} = \boxed{3.47}$$

69. (*a*) At a temperature of 30°C, the saturated vapor pressure, from Table 18-2, is 4240 Pa. If the relative humidity is 65%, then the water vapor pressure is 50% of the saturated vapor pressure.

$$0.65\left(4240\,\text{Pa}\right) = 2756\,\text{Pa} \approx \boxed{2800\,\text{Pa}}$$

(*b*) At a temperature of 5°C, the saturated vapor pressure, from Table 18-2, is 872 Pa. If the relative humidity is 75%, then the water vapor pressure is 75% of the saturated vapor pressure.

$$0.75\left(872\,\text{Pa}\right) = 654\,\text{Pa} \approx \boxed{650\,\text{Pa}}$$

70. First we find the pressure from the ideal gas equation.

$$P = \frac{nRT}{V} = \frac{\left(8.50\,\text{mol}\right)\left(8.314\,\text{J/mol•k}\right)\left(300\,\text{K}\right)}{0.220\,\text{m}^3} = 9.6367\times10^4\,\text{Pa} \approx \boxed{9.64\times10^4\,\text{Pa}}$$

Now find the pressure from the van der Waals equation.

$$P = \frac{RT}{(V/n)-b} - \frac{a}{(V/n)^2} = \frac{nRT}{V-nb} - \frac{an^2}{V^2}$$

$$= \frac{\left(8.50\,\text{mol}\right)\left(8.314\,\text{J/mol•k}\right)\left(300\,\text{K}\right)}{\left(0.220\,\text{m}^3\right)-\left(8.50\,\text{mol}\right)\left(4.5\times10^{-5}\,\text{m}^3\text{/mol}\right)} - \frac{\left(0.36\,\text{N•m}^4\text{/mol}^2\right)\left(8.50\,\text{mol}\right)^2}{\left(0.220\,\text{m}^3\right)^2}$$

$$= 9.5997\times10^4\,\text{Pa} \approx \boxed{9.60\times10^4\,\text{Pa}}$$

$$\%\,\text{error} = \left(\frac{P_{\text{ideal}} - P_{\substack{\text{van der}\\\text{Waals}}}}{P_{\substack{\text{van der}\\\text{Waals}}}}\right)\times100 = \left(\frac{9.6367\times10^4\,\text{Pa} - 9.5997\times10^4\,\text{Pa}}{9.5997\times10^4\,\text{Pa}}\right)\times100 \approx \boxed{0.39\%}$$

71. The mean free path is given by Eq. 18-10b.

$$\ell_{\text{M}} = \frac{1}{4\pi\sqrt{2}r^2\left(N/V\right)} = \frac{1}{4\pi\sqrt{2}\left(0.5\times10^{-10}\,\text{m}\right)^2\left(1\text{atom/cm}^3\right)\left(10^6\,\text{cm}^3\text{/m}^3\right)} = \boxed{2\times10^{13}\,\text{m}}$$

72. We combine the ideal gas law with Eq. 18-10b for the mean free path. From problem 45, we se that the diameter of the average air molecule is 3×10^{-10} m. Since air is mostly nitrogen molecules, this is a good approximation for the size of a nitrogen molecule.

$$PV = NkT \quad \rightarrow \quad \frac{N}{V} = \frac{P}{kT};$$

$$\ell_{\text{M}} = \frac{1}{4\pi\sqrt{2}r^2\left(N/V\right)} = \frac{1}{4\pi\sqrt{2}r^2\left(P/kT\right)} = \boxed{\frac{kT}{4\pi\sqrt{2}r^2P}}$$

$$\ell_{\text{M}} = \frac{kT}{4\pi\sqrt{2}r^2P} = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)\left(300\,\text{K}\right)}{4\pi\sqrt{2}\left(1.5\times10^{-10}\,\text{m}\right)^2 7.5\left(1.013\times10^5\,\text{Pa}\right)} = \boxed{1.4\times10^{-8}\,\text{m}}$$

Note that this is about 100 times the radius of the molecules.

73. Assume that the water is an ideal gas, and that the temperature is constant. From Table 18-2, saturated vapor pressure at 90°C is $7.01\times10^4\,\text{Pa}$, and so to have a relative humidity of 10%, the vapor pressure will be $7.01\times10^3\,\text{Pa}$. Use the ideal gas law to calculate the amount of water.

$$PV = nRT \;\rightarrow$$

$$n = \frac{PV}{RT} = \frac{\left(7.01\times10^3\,\text{Pa}\right)\left(8.5\,\text{m}^3\right)}{\left(8.314\,\text{J/mol•K}\right)\left(273+90\right)\text{K}} = 19.74\text{ moles}\left(\frac{18\times10^{-3}\,\text{kg}}{1\text{ mole}}\right) = \boxed{0.36\,\text{kg}}$$

74. Following the development of the kinetic molecular theory in the textbook, the tennis balls hitting the trash can lid are similar to the particles colliding with the walls of a container causing pressure. Quoting from the text, "the average force — averaged over many collisions — will be equal to the momentum change during one collision divided by the time between collisions." That average force must be the weight of the trash can lid in order to suspend it.

$$F_{\text{avg}} = M_{\text{lid}}g \;;\; F_{\text{avg}} = \frac{\Delta p}{\Delta t} = \frac{2m_{\text{ball}}v_{\text{ball}}}{\Delta t} \;\rightarrow\; \Delta t = \frac{2m_{\text{ball}}v_{\text{ball}}}{M_{\text{lid}}g}$$

The above expression is "seconds per ball," so its reciprocal will be "balls per second."

$$\text{balls/s} = \frac{1}{\Delta t} = \frac{M_{\text{lid}}g}{2m_{\text{ball}}v_{\text{ball}}} = \frac{\left(0.50\,\text{kg}\right)\left(9.80\,\text{m/s}^2\right)}{2\left(0.060\,\text{kg}\right)\left(12\,\text{m/s}\right)} = \boxed{3.4\text{ balls/s}}$$

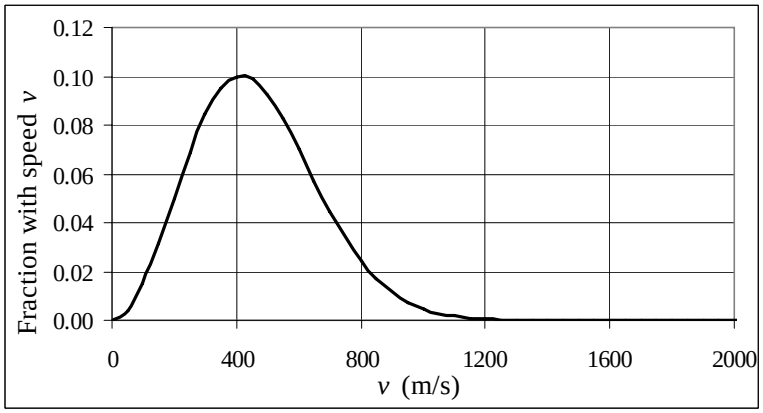
75. (*a*) The average time between collisions can be approximated as the mean free path divided by the mean speed. The highest frequency for a sound wave is the inverse of this average collision time. Combine the ideal gas law with Eq. 18-10b for the mean free path, and Eq. 18-7b for the mean speed.

$$PV = NkT \;\rightarrow\; \frac{N}{V} = \frac{P}{kT} \;;\; \ell_{\text{M}} = \frac{1}{4\pi\sqrt{2}r^2\left(N/V\right)} = \frac{1}{4\pi\sqrt{2}r^2\left(P/kT\right)} = \frac{kT}{4\pi\sqrt{2}r^2P} \;;$$

$$\overline{v} = \sqrt{\frac{8kT}{\pi m}} \;\rightarrow\; f_{\text{max}} = \frac{\overline{v}}{\ell_{\text{M}}} = \frac{\sqrt{\dfrac{8kT}{\pi m}}}{\dfrac{kT}{4\pi\sqrt{2}r^2P}} = \boxed{16Pr^2\sqrt{\frac{\pi}{mkT}}}$$

(*b*) We have estimated the molecular mass of air to be 29 u in problem 16, and the average molecular diameter to be $3\times10^{-10}\,\text{m}$ in problem 48.

$$f_{\text{max}} = 16Pr^2\sqrt{\frac{\pi}{mkT}}$$



$$= 16\left(1.013\times10^5\,\text{Pa}\right)\left(1.5\times10^{-10}\,\text{m}\right)^2\sqrt{\frac{\pi}{29\left(1.66\times10^{-27}\,\text{kg}\right)\left(1.38\times10^{-23}\,\text{J/K}\right)\left(293\,\text{K}\right)}}$$

$$= \boxed{4.6\times10^9\,\text{Hz}}$$

This frequency is about $\dfrac{4.6\times10^9\,\text{Hz}}{2.0\times10^4\,\text{Hz}} = \boxed{2.3\times10^5}$ larger than the highest frequency in the human audio range.

76. From section 18-2, the quantity $f(v)\,dv$ represents the number of molecules that have speeds between v and $v + dv$. So for a finite velocity range Δv, the number of molecules with speeds between v and $v + \Delta v$ is approximately $f(v)\,\Delta v$. If there are N total molecules, then the fraction with speeds between v and $v + \Delta v$ is $\dfrac{f(v)\,\Delta v}{N}$. We assume that we have air molecules with a molecular mass of 29, as given in problem 16.

$$f(v) = 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} v^2 e^{-\frac{1}{2}\frac{mv^2}{kT}} \quad \rightarrow \quad \frac{f(v)\,\Delta v}{N} = 4\pi \Delta v\left(\frac{m}{2\pi kT}\right)^{3/2} v^2 e^{-\frac{1}{2}\frac{mv^2}{kT}}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH18.XLS," on tab "Problem 18.76."

77. From section 18-2, the quantity $f(v)\,dv$ represents the number of molecules that have speeds between v and $v + dv$. The number of molecules with speeds greater than 1.5 times the most probable speed $v_p = \sqrt{\dfrac{2kT}{m}}$ is $\displaystyle\int_{1.5v_p}^{\infty} f(v)\,dv$. If there are N total molecules, then the fraction with speeds greater than $1.5v_p$ is $\dfrac{1}{N}\displaystyle\int_{1.5v_p}^{\infty} f(v)\,dv$. Since $\dfrac{1}{N}\displaystyle\int_0^{\infty} f(v)\,dv = 1$ (see problem 22a), we calculate the desired fraction as follows.

$$\frac{1}{N}\int_0^{\infty} f(v)\,dv = 1 = \frac{1}{N}\int_0^{1.5v_p} f(v)\,dv + \frac{1}{N}\int_{1.5v_p}^{\infty} f(v)\,dv \quad \rightarrow \quad \frac{1}{N}\int_{1.5v_p}^{\infty} f(v)\,dv = 1 - \frac{1}{N}\int_0^{1.5v_p} f(v)\,dv$$

We use a substation of variables to simplify the constants.

$$f(v) = 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} v^2 e^{-\frac{1}{2}\frac{mv^2}{kT}}$$

$$x = \frac{v}{v_p} = \frac{v}{\sqrt{2kT/m}} \quad \rightarrow \quad v^2 = \frac{2kT}{m}x^2 \quad \rightarrow \quad dv = \sqrt{\frac{2kT}{m}}\,dx$$

$$\frac{1}{N}\int_0^{1.5v_p} f(v)\,dv = \frac{1}{N}\int_0^{1.5v_p} 4\pi N\left(\frac{m}{2\pi kT}\right)^{3/2} v^2 e^{-\frac{1}{2}\frac{mv^2}{kT}}\,dv = \int_0^{1.5} 4\pi\left(\frac{m}{2\pi kT}\right)^{3/2} \frac{2kT}{m}x^2 e^{-x^2}\sqrt{\frac{2kT}{m}}\,dx$$

$$= \frac{4}{\sqrt{\pi}}\int_0^{1.5} x^2 e^{-x^2}\,dx$$

To do the integral, we approximate it as this sum: $\dfrac{4}{\sqrt{\pi}}\displaystyle\int_0^{1.5} x^2 e^{-x^2}\,dx \approx \frac{4}{\sqrt{\pi}}\sum_{i=1}^{n} x_i^2 e^{-x_i^2}\Delta x$, where $n = \dfrac{1.5}{\Delta x}$ is the number of intervals used to approximate the integral. We start with $\Delta x = 0.15$ and then try smaller intervals until the answers agree to within 2%. Here are the results of the numeric integration.

Δx	n	$\frac{4}{\sqrt{\pi}}\sum_{i=1}^{n} x_i^2 e^{-x_i^2}\Delta x$	% diff. from previous answer
0.15	10	0.8262	--
0.075	20	0.8074	2.3 %
0.03	50	0.7957	1.4 %

We approximate $\frac{1}{N}\int_0^{1.5v_p} f(v)\,dv = \frac{4}{\sqrt{\pi}}\int_0^{1.5} x^2 e^{-x^2}\,dx \approx 0.7957,$ and so $\frac{1}{N}\int_{1.5v_p}^{\infty} f(v)\,dv = 1 - 0.7975$ $= 0.2025 \approx \boxed{0.20}$. Using more sophisticated software gives an answer of 0.21. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH18.XLS," on tab "Problem 18.77."

78. For each temperature, a graph of pressure vs. volume was plotted, based on Eq. 18-9,

$$P = \frac{RT}{(V/n) - b} - \frac{a}{(V/n)^2}.$$

From the graphs, it would appear that the critical temperature for oxygen is approximately $\boxed{150\text{ K}}$.
The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH18.XLS," on tab "Problem 18.78."

CHAPTER 19: Heat and the First Law of Thermodynamics

Responses to Questions

1. When a jar of orange juice is vigorously shaken, the work done on it goes into heating the juice (increasing the kinetic energy of the molecules), mixing the components of the juice (liquid and pulp), and dissolving air in the juice (froth).

2. No. *Energy* is exchanged between them, not *temperature*. Once the objects have reached thermal equilibrium, they will have the same temperature. However, their temperature *changes* will not necessarily be the same.

3. (*a*) No. Because the internal energies of solids and liquids are complicated and include potential energies associated with the bonds between atoms and molecules, two objects may have different internal energies but the same temperature. Internal energy will also vary with the mass of the object. If two objects that are at different temperatures are placed in contact, there will be a net energy transfer from the hotter object to the colder one, regardless of their internal energies.
   (*b*) Yes. Just as in (*a*), the transfer of energy depends on the temperature difference between the two objects, which may not be directly related to the difference in internal energies.

4. Plants are damaged if the water inside their cells freezes. The latent heat of water is large, so if the cells are plump with water, rather than dry, it will take more time for them to lose enough heat to freeze. Well-hydrated plants are therefore less likely to be damaged if the temperature dips below freezing for a short time.

5. Because the specific heat of water is quite large, water can absorb a large amount of energy with a small increase in temperature. Water can be heated, then easily transported throughout a building, and will give off a large amount of energy as it cools. This makes water particularly useful in radiator systems.

6. The water on the cloth jacket will evaporate. Evaporation is a cooling process since energy is required to change the liquid water to vapor. If, for instance, radiant energy from the sun falls on the canteen, the energy will evaporate the water from the cloth cover instead of heating the water inside the canteen.

7. When water at 100ºC comes in contact with the skin, energy is transferred to the skin and the water begins to cool. When steam at 100ºC comes in contact with the skin, energy is transferred to the skin and the steam begins to condense to water at 100ºC. Steam burns are often more severe than water burns due to the energy given off by the steam as it condenses, before it begins to cool.

8. Energy is needed to convert water in the liquid state to the gaseous state (latent heat). Some of the energy needed to evaporate molecules on the surface comes from the internal energy of the water, thus decreasing the water temperature.

9. No. The water temperature cannot go above 100ºC, no matter how vigorously it is boiling. The rate at which potatoes cook depends on the temperature at which they are cooking.

10. Whether an animal freezes or not depends more on internal energy of the mass of air surrounding it than on the temperature. Temperature is a measure of the average kinetic energy of the molecules in a substance. If a mass of air in the upper atmosphere has a low density of fast moving molecules, it will have a high temperature but a low internal (or thermal) energy. Even though the molecules are moving quickly, there will be few collisions, and little energy transferred to the animal. The animal will also be radiating thermal energy, and so will quickly deplete its internal energy.

11. Energy is transferred from the water vapor to the glass as the water vapor condenses on the glass and then cools from the temperature of the surrounding air to the temperature of the glass. The glass (and the cold water inside) will heat up. No work is done, but heat is exchanged.

12. When a gas is compressed, work must be done on it by some outside force, such as a person pushing a piston. This work becomes the increase in internal energy of the gas, and if no gas is allowed to escape, an increase in internal energy results in faster average molecular speeds and a higher temperature. When a gas expands, it does work on the piston. If the gas is insulated so that no heat enters from the outside, then the energy for this work comes from the internal energy of the gas. A decrease in internal energy with no change in the number of molecules translates into a decrease in average molecular speed and therefore temperature.

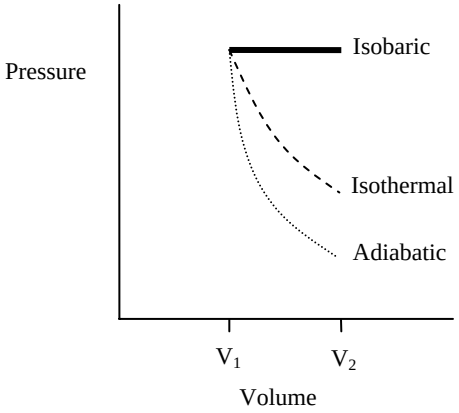
13. In an isothermal process, the temperature, and therefore the internal energy, of the ideal gas is constant. From the first law of thermodynamics, we know that if the change in the internal energy is zero, then the heat added to the system is equal to the work done by the system. Therefore, 3700 J of heat must have been added to the system.

14. Snow consists of crystals with tiny air pockets in between the flakes. Air is a good insulator, so when the Arctic explorers covered themselves with snow they were using its low thermal conductivity to keep heat from leaving their bodies. (In a similar fashion, down comforters keep you warm because of all the air trapped in between the feathers.) Snow would also protect the explorers from the very cold wind and prevent heat loss by convection.

15. Wet sand has been cooled by conduction (ocean water is usually cooler than the beach) and continues to be cooled by evaporation, and so will be cooler than dry sand. Wet sand will also feel cooler because of the thermal conductivity of water. The water in the sand will also cool your feet by evaporation.

16. Hot air furnaces often depend on natural convection. If the return air vent is blocked, convective currents in the room will not occur and the room will not be heated uniformly.

17. Yes. This is the case for any isothermal process or a process in which a substance changes state (melting/freezing, or condensing/evaporating).



18. Metabolism is a biochemical process by which living organisms get energy from food. If a body is doing work and losing heat, then its internal energy would drop drastically if there were no other source of energy. Metabolism (food) supplies this other source of energy. The first law of thermodynamics applies because the energy contributions from metabolism are included in Q.

19. When a gas is heated at constant volume, all of the energy added goes into increasing the internal energy, since no work is done. When a gas is heated at constant pressure, some of the added energy is used for the work needed to expand the gas, and less is available for increasing the internal energy. It takes more energy to raise the temperature of a gas by a given amount at constant pressure than at constant volume.

20. An adiabatic compression is one that takes place with no exchange of heat with the surroundings. During the compression, work is done on the gas. Since no heat leaves the gas, then the work results in an increase in the gas's internal energy by the same amount, and therefore an increase in its temperature. $\Delta E_{\text{int}} = Q - W$, so if $Q = 0$ then $\Delta E_{\text{int}} = -W$.

21. ΔE_{int} is proportional to the change in temperature. The change in the internal energy is zero for the isothermal process, largest for the isobaric process, and least (negative) for the adiabatic process. The work done, W, is the area under the curve and is greatest for the isobaric process and least for the adiabatic process. From the first law of thermodynamics, Q is the sum of ΔE_{int} and W and is zero for the adiabatic process and maximum for the isobaric process.

22. In general, cooler air will be nearer the floor and warmer air nearer the ceiling. The fan operating in either direction redistributes the air by creating convection currents. Set the fan so that it will blow air down in the summer, creating a breeze, which has a cooling effect by increasing evaporation. In the winter, set the fan so that it pulls air up. This will cause convection currents which will help mix warm and cool air without creating a direct breeze.

23. The actual insulating value comes from the air trapped between the down feathers. The more air is trapped, the greater the loft, and the lower the rate of thermal conduction. So loft determines the warmth of the sleeping bag or parka.

24. The use of "fins" increases the surface area of the heat sink. The greater the surface area, the more heat can be given off from the chip to the surroundings.

25. On a sunny day, the land heats faster than the water. The air over the land is also heated and it rises due to a decrease in density. The cooler air over the water is then pulled in to replace the rising air, creating an onshore or sea breeze.

26. At night, the Earth cools primarily through radiation of heat back into space. Clouds reflect energy back to the Earth and so the surface cools less on a cloudy night than on a clear one.

27. In direct sunlight, the solar radiation will heat the thermometer to a temperature greater than the surrounding air.

28. A premature baby will not have a well developed metabolism and will not produce much heat but will radiate heat to its surroundings. The surface of the incubator must be warmed so that the surface radiates sufficient heat back to the baby. In addition, a premature baby's skin is underdeveloped and the baby tends to lose moisture by evaporation. Since evaporation is a cooling process, this may dangerously cool the baby even in a warm incubator. The air in the incubator needs to be humid as well as warm. Finally, premature babies tend to have very little fat under the skin, so they are not well insulated, and have trouble maintaining body temperature without assistance.

29. If a house is built directly on the ground or on a slab, it can only lose energy through the floor by conduction. If air can circulate under the house, then energy loss also can occur due to convection and evaporation, especially if air is moving through the space.

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

30. A thermos bottle is designed to minimize heat transfer between the liquid contents and the outside air, even when the temperature difference is large. Heat transfer by radiation is minimized by the silvered lining. Shiny surfaces have very low emissivity, *e*, and thus the net rate of energy flow by radiation between the contents of the thermos and the outside air will be small. Heat transfer by conduction and convection will be minimized by the vacuum between the inner and outer walls of the thermos, since both these methods require a medium to transport heat.

31. Water has a greater thermal conductivity than air. Water at 22ºC will feel cooler than air at the same temperature because the rate of heat transfer away from the body will be greater.

32. The south-facing windows will allow radiant heat from the sun to enter the room to contribute to the heating, so that less heat will need to be provided internally.

33. (*a*) (1) Ventilation around the edges: convection; (2) through the frame: conduction; (3) through the glass panes: conduction and radiation.
(*b*) Heavy curtains help prevent all three mechanisms for heat loss. They physically block convection currents and they are opaque and insulating and therefore reduce heat loss by radiation and conduction.

34. When the sun reaches the slope of the mountain early in the day, the ground is warmed by radiation. The air above the ground is also warmed and rises by convection. This rising air will move up the slope. When the slope is in shadow, the air cools and the convection currents reverse.

35. Wood has a much lower thermal conductivity than metals and so will feel cooler because the rate of heat transfer away from the hand will be less.

36. Shiny surfaces have low values of *e*, the emissivity. Thus, the net rate of heat flow from the person to the surroundings (outside the blanket) will be low, since most of the heat is reflected by blanket back to the person, and the person will stay warmer. The blanket will also prevent energy loss due to wind (convection).

37. The temperature of the air around cities near oceans is moderated by the presence of large bodies of water which act like a heat reservoir. Water has a high heat capacity. It will absorb energy in the summer with only a small temperature increase, and radiate energy in the winter, with a small temperature decrease.

Solutions to Problems

In solving these problems, the authors did not always follow the rules of significant figures rigidly. We tended to take quoted temperatures as correct to the number of digits shown, especially where other values might indicate that.

1. The kcal is the heat needed to raise 1 kg of water by 1C°. Use this relation to find the change in the temperature.

$$(8700\,\text{J})\left(\frac{1\text{ kcal}}{4186\text{ J}}\right)\frac{(1\text{kg})(1\text{C}^\circ)}{1\text{ kcal}}\left(\frac{1}{3.0\,\text{kg}}\right) = 0.69\,\text{C}^\circ$$

Thus the final temperature is $10.0°\text{C} + 0.69°\text{C} = \boxed{10.7°\text{C}}$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2. Find the mass of warmed water from the volume of water and its density of $1000\,\text{kg}/\text{m}^3$. Then use the fact that 1 kcal of energy raises 1 kg of water by $1\text{C}°$, and that the water warms by $25\text{C}°$.

$$V = At = \frac{m}{\rho} \;\rightarrow\; m = \rho At = \left(1025\,\text{kg}/\text{m}^3\right)\left(1.0\,\text{m}^2\right)\left(0.50\times10^{-3}\,\text{m}\right) = 0.5125\,\text{kg}$$

$$\left(0.5125\,\text{kg}\right)\left(25\text{C}°\right)\frac{\left(1\,\text{kcal}\right)}{\left(1\,\text{kg}\right)\left(1\text{C}°\right)} = 12.8\,\text{kcal}\;;\; 12.8\,\text{kcal}\left(\frac{1\,\text{bar}}{300\,\text{kcal}}\right) = \boxed{0.043\,\text{bars}}$$

3. (*a*) $2500\text{ Cal}\left(\dfrac{4.186\times10^3\,\text{J}}{1\text{ Cal}}\right) = \boxed{1.0\times10^7\,\text{J}}$

(*b*) $2500\text{ Cal}\left(\dfrac{1\text{ kWh}}{860\text{ Cal}}\right) = \boxed{2.9\text{ kWh}}$

(*c*) At 10 cents per day, the food energy costs $\boxed{\$0.29\text{ per day}}$. It would be practically impossible to feed yourself in the United States on this amount of money.

4. Assume that we are at the surface of the Earth so that 1 lb is equivalent to 0.454 kg.

$$1\,\text{Btu} = \left(1\text{ lb}\right)\left(1\text{F}°\right)\left(\frac{0.454\text{ kg}}{1\text{ lb}}\right)\left(\frac{5/9\,\text{C}°}{1\,\text{F}°}\right)\frac{1\text{ kcal}}{\left(1\text{ kg}\right)\left(1\text{C}°\right)} = 0.2522\,\text{kcal} \approx \boxed{0.252\text{ kcal}}$$

$$0.2522\text{ kcal}\left(\frac{4186\text{ J}}{1\text{ kcal}}\right) = \boxed{1056\,\text{J}}$$

5. The energy generated by using the brakes must equal the car's initial kinetic energy, since its final kinetic energy is 0.

$$Q = \tfrac{1}{2}mv_0^2 = \tfrac{1}{2}\left(1.2\times10^3\,\text{kg}\right)\left[\left(95\,\text{km/h}\right)\left(\frac{1\,\text{m/s}}{3.6\,\text{km/h}}\right)\right]^2 = 4.178\times10^5\,\text{J} \approx \boxed{4.2\times10^5\,\text{J}}$$

$$\left(4.178\times10^5\,\text{J}\right)\left(\frac{1\text{ kcal}}{4186\text{ J}}\right) = 99.81\,\text{kcal} \approx \boxed{1.0\times10^2\,\text{kcal}}$$

6. The wattage rating is 350 Joules per second. Note that 1 L of water has a mass of 1 kg.

$$\left[\left(2.5\times10^{-1}\,\text{L}\right)\left(\frac{1\text{ kg}}{1\text{ L}}\right)\left(60\text{C}°\right)\right]\frac{1\text{ kcal}}{\left(1\text{ kg}\right)\left(1\text{C}°\right)}\left(\frac{4186\text{ J}}{\text{kcal}}\right)\left(\frac{1\text{ s}}{350\text{ J}}\right) = \boxed{180\,\text{s} = 3.0\,\text{min}}$$

7. The heat absorbed can be calculated from Eq. 19-2. Note that 1 L of water has a mass of 1 kg.

$$Q = mc\Delta T = \left[\left(18\,\text{L}\right)\left(\frac{1\times10^{-3}\,\text{m}^3}{1\text{ L}}\right)\left(\frac{1.0\times10^3\,\text{kg}}{1\text{ m}^3}\right)\right]\left(4186\,\text{J/kg•C}°\right)\left(95°\text{C} - 15°\text{C}\right) = \boxed{6.0\times10^6\,\text{J}}$$

8. The specific heat can be calculated from Eq. 19-2.

$$Q = mc\Delta T \;\rightarrow\; c = \frac{Q}{m\Delta T} = \frac{1.35\times10^5\,\text{J}}{\left(5.1\text{ kg}\right)\left(37.2°\text{C} - 18.0°\text{C}\right)} = 1379\,\text{J/kg•C}° \approx \boxed{1400\,\text{J/kg•C}°}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9. (*a*) The heat absorbed can be calculated from Eq. 19-2. Note that 1 L of water has a mass of 1 kg.

$$Q = mc\Delta T = \left[(1.0\,\text{L}) \left(\frac{1\times10^{-3}\,\text{m}^3}{1\,\text{L}} \right) \left(\frac{1.0\times10^{3}\,\text{kg}}{1\,\text{m}^3} \right) \right] (4186\,\text{J/kg•C°})(100°\text{C} - 20°\text{C})$$

$$= 3.349\times10^{5}\,\text{J} \approx \boxed{3.3\times10^{5}\,\text{J}}$$

(*b*) Power is the rate of energy usage.

$$P = \frac{\Delta E}{\Delta t} = \frac{Q}{\Delta t} \quad \rightarrow \quad \Delta t = \frac{Q}{P} = \frac{3.349\times10^{5}\,\text{J}}{100\,\text{W}} \approx \boxed{3300\,\text{s}} \approx 56\,\text{min}$$

10. The heat absorbed by all three substances is given by Eq. 19-2, $Q = mc\Delta T$. Thus the amount of mass can be found as $m = \dfrac{Q}{c\Delta T}$. The heat and temperature change are the same for all three substances.

$$m_{\text{Cu}} : m_{\text{Al}} : m_{\text{H}_2\text{O}} = \frac{Q}{c_{\text{Cu}}\Delta T} : \frac{Q}{c_{\text{Al}}\Delta T} : \frac{Q}{c_{\text{H}_2\text{O}}\Delta T} = \frac{1}{c_{\text{Cu}}} : \frac{1}{c_{\text{Al}}} : \frac{1}{c_{\text{H}_2\text{O}}} = \frac{1}{390} : \frac{1}{900} : \frac{1}{4186}$$

$$= \frac{4186}{390} : \frac{4186}{900} : \frac{4186}{4186} = 10.7 : 4.65 : 1 \approx \boxed{11 : 4.7 : 1}$$

11. The heat must warm both the water and the pot to 100°C. The heat is also the power times the time.

$$Q = Pt = \left(m_{\text{Al}}c_{\text{Al}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}} \right) \Delta T_{\text{H}_2\text{O}} \quad \rightarrow$$

$$t = \frac{\left(m_{\text{Al}}c_{\text{Al}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}} \right) \Delta T_{\text{H}_2\text{O}}}{P} = \frac{\left[(0.28\,\text{kg})(900\,\text{J/kg•C°}) + (0.75\,\text{kg})(4186\,\text{J/kg•C°}) \right] (92\,\text{C°})}{750\,\text{W}}$$

$$= 416\,\text{s} \approx \boxed{420\,\text{s or } 6.9\,\text{min}}$$

12. The heat lost by the horseshoe must be equal to the heat gained by the iron pot and the water. Note that 1 L of water has a mass of 1 kg.

$$m_{\text{shoe}}c_{\text{Fe}} \left(T_{\text{shoe}} - T_{\text{eq}} \right) = m_{\text{pot}}c_{\text{Fe}} \left(T_{\text{eq}} - T_{\text{pot}} \right) + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}} \left(T_{\text{eq}} - T_{\text{H}_2\text{O}} \right)$$

$$(0.40\,\text{kg})(450\,\text{J/kg•C°})(T_{\text{shoe}} - 25.0°\text{C}) = (0.30\,\text{kg})(450\,\text{J/kg•C°})(25.0°\text{C} - 20.0°\text{C})$$

$$+ (1.05\,\text{kg})(4186\,\text{J/kg•C°})(25.0°\text{C} - 20.0°\text{C})$$

$$T_{\text{shoe}} = 150.8°\text{C} \approx \boxed{150°\text{C}}$$

13. The heat gained by the glass thermometer must be equal to the heat lost by the water.

$$m_{\text{glass}}c_{\text{glass}} \left(T_{\text{eq}} - T_{\text{glass}} \right) = m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}} \left(T_{\text{H}_2\text{O}} - T_{\text{eq}} \right)$$

$$(31.5\,\text{g})(0.20\,\text{cal/g•C°})(39.2°\text{C} - 23.6°\text{C}) = (135\,\text{g})(1.00\,\text{cal/g•C°})\left(T_{\text{H}_2\text{O}} - 39.2°\text{C} \right)$$

$$T_{\text{H}_2\text{O}} = \boxed{39.9°\text{C}}$$

14. The heat released by the 15 grams of candy in the burning is equal to the heat absorbed by the aluminum and water.

$$Q_{\substack{15\,\text{g} \\ \text{candy}}} = \left(m_{\text{Al}}c_{\text{Al}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}} \right) \Delta T$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \left[(0.325\text{ kg} + 0.624\text{ kg})(0.22\,\text{kcal/kg•C°}) + (2.00\text{ kg})(1.00\,\text{kcal/kg•C°})\right](53.5°\text{C} - 15.0°\text{C})$$
$$= 85.04\,\text{kcal}$$

The heat released by 65 grams of the candy would be 65/15 times that released by the 15 grams.

$$Q_{\substack{65\text{g}\\\text{candy}}} = \tfrac{65}{15} Q_{\substack{15\text{g}\\\text{candy}}} = \tfrac{65}{15}(85.04\text{ kcal}) = 369\,\text{kcal} \approx \boxed{370\,\text{Cal}}$$

15. The heat lost by the iron must be the heat gained by the aluminum and the glycerin.

$$m_{\text{Fe}} c_{\text{Fe}} \left(T_{i\,\text{Fe}} - T_{\text{eq}}\right) = m_{\text{Al}} c_{\text{Al}} \left(T_{\text{eq}} - T_{i\,\text{Al}}\right) + m_{\text{gly}} c_{\text{gly}} \left(T_{\text{eq}} - T_{i\,\text{gly}}\right)$$
$$(0.290\text{ kg})(450\,\text{J/kg•C°})(142\text{C°}) = (0.095\text{ kg})(900\,\text{J/kg•C°})(28\text{C°}) + (0.250\text{ kg})\, c_{\text{gly}}\,(28\text{C°})$$
$$c_{\text{gly}} = 2305\,\text{J/kg•C°} \approx \boxed{2300\,\text{J/kg•C°}}$$

16. (*a*) Since $Q = mc\Delta T$ and $Q = C\Delta T$, equate these two expressions for Q and solve for C.

$$Q = mc\Delta T = C\Delta T \quad \rightarrow \quad \boxed{C = mc}$$

(*b*) For 1.0 kg of water: $C = mc = (1.0\text{ kg})\left(4186\,\text{J/kg•C}^{\text{o}}\right) = \boxed{4200\,\text{J/C}^{\text{o}}}$

(*c*) For 35 kg of water: $C = mc = (35\text{ kg})\left(4186\,\text{J/kg•C}^{\text{o}}\right) = \boxed{1.5\times10^{5}\,\text{J/C}^{\text{o}}}$

17. We assume that all of the kinetic energy of the hammer goes into heating the nail.

$$KE = Q \quad \rightarrow \quad 10\left(\tfrac{1}{2} m_{\text{hammer}} v_{\text{hammer}}^2\right) = m_{\text{nail}} c_{\text{Fe}} \Delta T \quad \rightarrow$$
$$\Delta T = \frac{10\left(\frac{1}{2} m_{\text{hammer}} v_{\text{hammer}}^2\right)}{m_{\text{nail}} c_{\text{Fe}}} = \frac{5(1.20\text{ kg})(7.5\,\text{m/s})^2}{(0.014\text{ kg})(450\,\text{J/kg•C°})} = 53.57\,\text{C°} \approx \boxed{54\,\text{C°}}$$

18. The silver must be heated to the melting temperature and then melted.

$$Q = Q_{\text{heat}} + Q_{\text{melt}} = mc\Delta T + mL_{\text{fusion}}$$
$$= (26.50\text{ kg})(230\,\text{J/kg•C°})(961°\text{C} - 25°\text{C}) + (26.50\text{ kg})\left(0.88\times10^{5}\,\text{J/kg}\right) = \boxed{8.0\times10^{6}\,\text{J}}$$

19. Assume that the heat from the person is only used to evaporate the water. Also, we use the heat of vaporization at room temperature (585 kcal/kg), since the person's temperature is closer to room temperature than 100°C.

$$Q = mL_{\text{vap}} \quad \rightarrow \quad m = \frac{Q}{L_{\text{vap}}} = \frac{180\,\text{kcal}}{585\,\text{kcal/kg}} = 0.308\,\text{kg} \approx \boxed{0.31\,\text{kg}} = 310\,\text{mL}$$

20. Assume that all of the heat lost by the ice cube in cooling to the temperature of the liquid nitrogen is used to boil the nitrogen, and so none is used to raise the temperature of the nitrogen. The boiling point of the nitrogen is $77\,\text{K} = -196^{\text{o}}\,\text{C}$.

$$m_{\text{ice}} c_{\text{ice}} \left(T_{\substack{\text{ice}\\\text{initial}}} - T_{\substack{\text{ice}\\\text{final}}}\right) = m_{\text{nitrogen}} L_{\text{vap}} \quad \rightarrow$$
$$m_{\text{nitrogen}} = \frac{m_{\text{ice}} c_{\text{ice}} \left(T_{\substack{\text{ice}\\\text{initial}}} - T_{\substack{\text{ice}\\\text{final}}}\right)}{L_{\text{vap}}} = \frac{\left(3.5\times10^{-2}\,\text{kg}\right)(2100\,\text{J/kg•C°})(0°\text{C} - -196°\text{C})}{200\times10^{3}\,\text{J/kg}} = \boxed{7.2\times10^{-2}\,\text{kg}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21. (*a*) The energy absorbed from the body must warm the snow to the melting temperature, melt the snow, and then warm the melted snow to the final temperature.

$$Q_a = \underset{\text{snow}}{Q_{\text{warm}}} + Q_{\text{melt}} + \underset{\text{liquid}}{Q_{\text{warm}}} = mc_{\text{snow}}\Delta T_1 + mL_{\text{fusion}} + mc_{\text{liquid}}\Delta T_2 = m\left[c_{\text{snow}}\Delta T_1 + L_{\text{fusion}} + c_{\text{liquid}}\Delta T_2\right]$$

$$= (1.0\text{ kg})\left[(2100\text{ J/kg•C°})(10\text{ C°}) + (3.33\times10^5\text{ J/kg}) + (4186\text{ J/kg•C°})(37\text{ C°})\right]$$

$$= \boxed{5.1\times10^5\text{ J}}$$

(*b*) The energy absorbed from the body only has to warm the melted snow to the final temperature.

$$Q_b = \underset{\text{liquid}}{Q_{\text{heat}}} = mc_{\text{liquid}}\Delta T_2 = (1.0\text{ kg})(4186\text{ J/kg•C°})(35\text{ C°}) = \boxed{1.5\times10^5\text{ J}}$$

22. (*a*) The heater must heat both the boiler and the water at the same time.

$$Q_1 = Pt_1 = \left(m_{\text{Fe}}c_{\text{Fe}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\right)\Delta T \quad \rightarrow$$

$$t_1 = \frac{\left(m_{\text{Fe}}c_{\text{Fe}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\right)\Delta T}{P} = \frac{\left[(180\text{ kg})\left(450\text{ J/kg•C}^\text{o}\right) + (730\text{ kg})\left(4186\text{ J/kg•C}^\text{o}\right)\right]\left(82\text{ C}^\text{o}\right)}{5.2\times10^7\text{ J/h}}$$

$$= 4.946\text{ h} \approx \boxed{4.9\text{ h}}$$

(*b*) Assume that after the water starts to boil, all the heat energy goes into boiling the water, and none goes to raising the temperature of the iron or the steam.

$$Q_2 = Pt_2 = m_{\text{H}_2\text{O}}L_{\text{vap}} \quad \rightarrow \quad t_2 = \frac{m_{\text{H}_2\text{O}}L_{\text{vap}}}{P} = \frac{(730\text{ kg})\left(22.6\times10^5\text{ J/kg}\right)}{5.2\times10^7\text{ J/h}} = 31.727\text{ h}$$

Thus the total time is $t_1 + t_2 = 4.946\text{ h} + 31.727\text{ h} = 36.673\text{ h} \approx \boxed{37\text{ h}}$

23. We assume that the cyclist's energy is only going to evaporation, not any heating. Then the energy needed is equal to the mass of the water times the latent heat of vaporization for water. Note that 1 L of water has a mass of 1 kg. Also, we use the heat of vaporization at room temperature (585 kcal/kg), since the cyclist's temperature is closer to room temperature than 100°C.

$$Q = m_{\text{H}_2\text{O}}L_{\text{vap}} = (8.0\text{ kg})(585\text{ kcal/kg}) = \boxed{4700\text{ kcal}}$$

24. The heat lost by the aluminum and the water must equal the heat needed to melt the mercury and to warm the mercury to the equilibrium temperature.

$$m_{\text{Al}}c_{\text{Al}}\left(T_{\text{Al}} - T_{\text{eq}}\right) + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\left(T_{\text{H}_2\text{O}} - T_{\text{eq}}\right) = m_{\text{Hg}}\left[L_{\text{fusion}} + c_{\text{Hg}}\left(T_{\text{eq}} - T_{\text{melt}}\right)\right]$$

$$L_{\text{fusion}} = \frac{m_{\text{Al}}c_{\text{Al}}\left(T_{\text{Al}} - T_{\text{eq}}\right) + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\left(T_{\text{H}_2\text{O}} - T_{\text{eq}}\right)}{m_{\text{Hg}}} - c_{\text{Hg}}\left(T_{\text{eq}} - T_{\text{melt}}\right)$$

$$= \frac{\left[(0.620\text{ kg})(900\text{ J/kg•C°}) + (0.400\text{ kg})(4186\text{ J/kg•C°})\right](12.80\text{°C} - 5.06\text{°C})}{1.00\text{ kg}}$$

$$-(138\text{ J/kg•C°})\left[5.06\text{°C} - (-39.0\text{°C})\right]$$

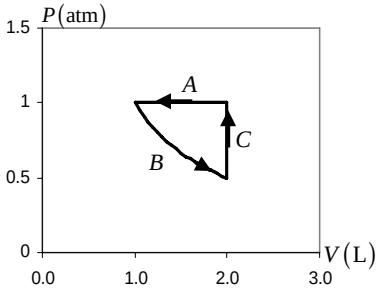
$$= \boxed{1.12\times10^4\text{ J/kg}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25. The kinetic energy of the bullet is assumed to warm the bullet and melt it.

$$\tfrac{1}{2}mv^2 = Q = mc_{\text{Pb}}\left(T_{\text{melt}} - T_{\text{initial}}\right) + mL_{\text{fusion}} \quad \rightarrow$$

$$v = \sqrt{2\left[c_{\text{Pb}}\left(T_{\text{melt}} - T_{\text{initial}}\right) + L_{\text{fusion}}\right]} = \sqrt{2\left[\left(130\,\text{J/kg•C°}\right)\left(327°\text{C} - 20°\text{C}\right) + \left(0.25\times10^5\,\text{J/kg}\right)\right]}$$



$$= \boxed{360\,\text{m/s}}$$

26. Assume that all of the melted ice stays at 0°C, so that all the heat is used in melting ice, and none in warming water. The available heat is half of the original kinetic energy

$$\tfrac{1}{2}\left(\tfrac{1}{2}m_{\text{skater}}v^2\right) = Q = m_{\text{ice}}L_{\text{fusion}} \quad \rightarrow$$

$$m_{\text{ice}} = \frac{\frac{1}{4}m_{\text{skater}}v^2}{L_{\text{fusion}}} = \frac{\frac{1}{4}\left(58\,\text{kg}\right)\left(7.5\,\text{m/s}\right)^2}{3.33\times10^5\,\text{J/kg}} = \boxed{2.4\times10^{-3}\,\text{kg}} = 2.4\,\text{g}$$

27. Segment *A* is the compression at constant pressure. Since the process is at a constant pressure, the path on the diagram is horizontal from 2.0 L to 1.0 L.

Segment *B* is the isothermal expansion. Since the temperature is constant, the ideal gas law says that the product *PV* is constant. Since the volume is doubled, the pressure must be halved, and so the final point on this segment is at a pressure of 0.5 atm. The path is a piece of a hyperbola.

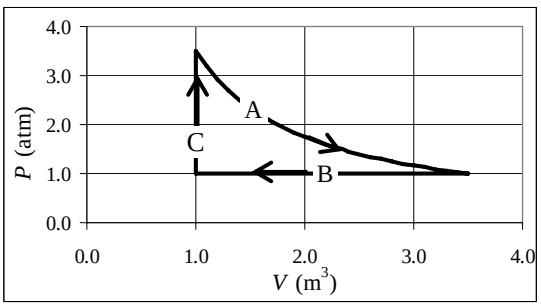
Segment *C* is the pressure increase at constant volume. Since the process is at a constant volume, the path on the diagram is vertical from 0.5 atm to 1.0 atm.

28. (*a*) The work done by a gas at constant pressure is found from Eq. 19-9a.

$$W = P\Delta V = \left(1\,\text{atm}\right)\left(\frac{1.01\times10^5\,\text{Pa}}{1\,\text{atm}}\right)\left(18.2\,\text{m}^3 - 12.0\,\text{m}^3\right) = 6.262\times10^5\,\text{J} \approx \boxed{6.3\times10^5\,\text{J}}$$

(*b*) The change in internal energy is calculated from the first law of thermodynamics

$$\Delta E_{\text{int}} = Q - W = \left(1250\,\text{kcal}\right)\left(\frac{4186\,\text{J}}{1\,\text{kcal}}\right) - 6.262\times10^5\,\text{J} = \boxed{4.60\times10^6\,\text{J}}$$



29. (*a*) Since the container has rigid walls, there is no change in volume.

$$W = P\Delta V = \boxed{0\,\text{J}}$$

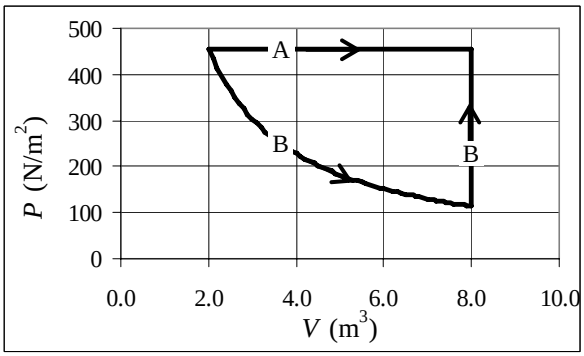
(*b*) Use the first law of thermodynamics to find the change in internal energy.

$$\Delta E_{\text{int}} = Q - W = \left(-365\,\text{kJ}\right) - 0 = \boxed{-365\,\text{kJ}}$$

30. Segment *A* is the isothermal expansion. The temperature and the amount of gas are constant, so $PV = nRT$ is constant. Since the pressure is reduced by a factor of 3.5, the volume increases by a factor of 3.5, to a final volume of 3.5 L. Segment *B* is the compression at constant pressure, and segment *C* is the pressure increase at constant volume. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH19.XLS," on tab "Problem 19.30."

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31. (*a*) No work is done during the first step, since the volume is constant. The work in the second step is given by $W = P\Delta V$.



$$W = P\Delta V = (1.4\text{ atm})\left(\frac{1.01\times10^5\text{ Pa}}{1\text{ atm}}\right)(9.3\text{ L} - 5.9\text{ L})\left(\frac{1\times10^{-3}\text{ m}^3}{1\text{ L}}\right) = \boxed{480\text{ J}}$$

(*b*) Since there is no overall change in temperature, $\Delta E_{\text{int}} = \boxed{0\text{ J}}$

(*c*) The heat flow can be found from the first law of thermodynamics.

$$\Delta E_{\text{int}} = Q - W \;\rightarrow\; Q = \Delta E_{\text{int}} + W = 0 + 480\text{ J} = \boxed{480\text{ J (into the gas)}}$$

32. (*a*) See the diagram. The isobaric expansion is just a horizontal line on the graph.

(*b*) The work done is found from Eq. 19-9a.

$$W = P\Delta V$$
$$= (455\text{ N/m}^2)(8.00\text{ m}^3 - 2.00\text{ m}^3)$$
$$= \boxed{2730\text{ J}}$$

The change in internal energy depends on the temperature change, which can be related to the ideal gas law, $PV = nRT$.

$$\Delta E_{\text{int}} = \tfrac{3}{2}nR\Delta T = \tfrac{3}{2}(nRT_2 - nRT_1)$$
$$= \tfrac{3}{2}\left[(PV)_2 - (PV)_1\right] = \tfrac{3}{2}P\Delta V = \tfrac{3}{2}W = \tfrac{3}{2}(2730\text{ J}) = \boxed{4.10\times10^3\text{ J}}$$

(*c*) For the isothermal expansion, since the volume expands by a factor of 4, the pressure drops by a factor of 4 to 114 N/m^2. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH19.XLS," on tab "Problem 19.32."

(*d*) The change in internal energy only depends on the initial and final temperatures. Since those temperatures are the same for process (B) as they are for process (A), the internal energy change is the same for process (B) as for process (A), $\boxed{4.10\times10^3\text{ J}}$.

33. (*a*) The work done by an ideal gas during an isothermal volume change is given by Eq. 19-8.

$$W = nRT\ln\frac{V_2}{V_1} = (2.60\text{ mol})(8.314\text{ J/mol•K})(290\text{ K})\ln\frac{7.00\text{ m}^3}{3.50\text{ m}^3} = 4345.2\text{ J} \approx \boxed{4350\text{ J}}$$

(*b*) Since the process is isothermal, there is no internal energy change. Apply the first law of thermodynamics.

$$\Delta E_{\text{int}} = Q - W = 0 \;\rightarrow\; Q = W = \boxed{4350\text{ J}}$$

(*c*) Since the process is isothermal, there is no internal energy change, and so $\boxed{\Delta E_{\text{int}} = 0}$.

34. (*a*) Since the process is adiabatic, $Q = \boxed{0\text{ J}}$

(*b*) Use the first law of thermodynamics to find the change in internal energy. The work is done on the gas, and so is negative.

$$\Delta E_{\text{int}} = Q - W = 0 - (-2850\text{ J}) = \boxed{2850\text{ J}}$$

(*c*) Since the internal energy is proportional to the temperature, a rise in internal energy means a rise in temperature.

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35. Since the expansion is adiabatic, there is no heat flow into or out of the gas. Use the first law of thermodynamics to calculate the temperature change.

$$\Delta E_{\text{int}} = Q - W \;\rightarrow\; \tfrac{3}{2} nR\Delta T = 0 - W \;\rightarrow$$

$$\Delta T = -\tfrac{2}{3}\frac{W}{nR} = -\frac{2(7500\text{ J})}{3(1.5\text{ mol})(8.315\text{J/mol•K})} = -401\text{K} = \boxed{-4.0\times10^{2}\text{K}}$$

36. (*a*) The initial volume of the water is found from its mass and density. The final volume is found from the ideal gas law. The work done at constant pressure is given by Eq. 19-9a.

$$V_1 = \frac{m}{\rho} = \frac{(1.00\text{kg})}{(1.00\times10^{3}\text{ kg/m}^3)} = 1.00\times10^{-3}\text{m}^3$$

$$V_2 = \frac{nRT}{P_2} = \frac{(1.00\text{kg})\left(\frac{1\text{mol}}{0.018\text{kg}}\right)(8.315\text{J/mol•K})(373\text{K})}{1.013\times10^{5}\text{Pa}} = 1.70\text{m}^3$$

Note that the initial volume is negligible. We might have assumed that since the original state was liquid, that the gas volume was 0 to begin with, without significant error.

$$W = P\Delta V = (1.013\times10^{5}\text{Pa})(1.70\text{m}^3) = 1.722\times10^{5}\text{J} \approx \boxed{1.72\times10^{5}\text{J}}$$

(b) The heat added to the system is calculated from the latent heat of vaporization. Then the first law of thermodynamics will give the internal energy change.

$$Q = mL_{\text{V}} = (1.00\text{kg})(2260\text{kJ/kg}) = 2260\text{kJ} = 2.26\times10^{6}\text{J}$$

$$\Delta E_{\text{int}} = Q - W = 2.26\times10^{6}\text{J} - 1.72\times10^{5}\text{J} = \boxed{2.09\times10^{6}\text{J}}$$

37. The work done by an ideal gas during an isothermal volume change is given by Eq. 19-8.

$$W = nRT\ln\frac{V_{\text{B}}}{V_{\text{A}}} = P_{\text{A}}V_{\text{A}}\ln\frac{V_{\text{B}}}{V_{\text{A}}} = (1.013\times10^{5}\text{Pa})(3.50\times10^{-3}\text{m}^3)\left(\ln\frac{1.80\text{L}}{3.50\text{L}}\right) = -236\text{J}$$

The work done by an external agent is the opposite of the work done by the gas, $\boxed{236\text{J}}$.

38. For the path ac, use the first law of thermodynamics to find the change in internal energy.

$$\Delta E_{\underset{\text{ac}}{\text{int}}} = Q_{\text{ac}} - W_{\text{ac}} = -63\text{ J} - (-35\text{ J}) = -28\text{ J}$$

Since internal energy only depends on the initial and final temperatures, this ΔE_{int} applies to any path that starts at a and ends at c. And for any path that starts at c and ends at a,

$\Delta E_{\underset{\text{ca}}{\text{int}}} = -\Delta E_{\underset{\text{ac}}{\text{int}}} = 28$ J.

(*a*) Use the first law of thermodynamics to find Q_{abc}.

$$\Delta E_{\underset{\text{abc}}{\text{int}}} = Q_{\text{abc}} - W_{\text{abc}} \;\rightarrow\; Q_{\text{abc}} = \Delta E_{\underset{\text{abc}}{\text{int}}} + W_{\text{abc}} = -28\text{J} + (-54\text{J}) = \boxed{-82\text{J}}$$

(*b*) Since the work along path bc is 0, $W_{\text{abc}} = W_{\text{ab}} = P_{\text{b}}\Delta V_{\text{ab}} = P_{\text{b}}(V_{\text{b}} - V_{\text{a}})$. Also note that the work along path da is 0.

$$W_{\text{cda}} = W_{\text{cd}} = P_{\text{c}}\Delta V_{\text{cd}} = P_{\text{c}}(V_{\text{d}} - V_{\text{c}}) = \tfrac{1}{2}P_{\text{b}}(V_{\text{a}} - V_{\text{b}}) = -\tfrac{1}{2}W_{\text{abc}} = -\tfrac{1}{2}(-54\text{J}) = \boxed{27\text{J}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) Use the first law of thermodynamics to find Q_{abc}.

$$\Delta E_{\substack{\text{int}\\\text{cda}}} = Q_{\text{cda}} - W_{\text{cda}} \rightarrow Q_{\text{cda}} = \Delta E_{\substack{\text{int}\\\text{cda}}} + W_{\text{cda}} = 28\,\text{J} + 27\,\text{J} = \boxed{55\,\text{J}}$$

(*d*) As found above, $E_{\text{int,a}} - E_{\text{int,c}} = \Delta E_{\substack{\text{int}\\\text{ca}}} = -\Delta E_{\substack{\text{int}\\\text{ac}}} = \boxed{28\,\text{J}}$

(*e*) Since $E_{\text{int,d}} - E_{\text{int,c}} = 12\,\text{J}$, $E_{\text{int,d}} = E_{\text{int,c}} + 12\,\text{J}$ and so $\Delta E_{\substack{\text{int}\\\text{da}}} = E_{\text{int,a}} - E_{\text{int,d}} = E_{\text{int,a}} - \left(E_{\text{int,c}} + 12\ \text{J}\right)$ which then gives $\Delta E_{\substack{\text{int}\\\text{da}}} = \Delta E_{\substack{\text{int}\\\text{ca}}} - 12\,\text{J} = 28\,\text{J} - 12\,\text{J} = 16\,\text{J}$. Use the first law of thermodynamics to find Q_{da}.

$$\Delta E_{\substack{\text{int}\\\text{da}}} = Q_{\text{da}} - W_{\text{da}} \rightarrow Q_{\text{da}} = \Delta E_{\substack{\text{int}\\\text{da}}} + W_{\text{da}} = 16\,\text{J} + 0 = \boxed{16\,\text{J}}$$

39. We are given that $Q_{\text{ac}} = -85\,\text{J}$, $W_{\text{ac}} = -55\ \text{J}$, $W_{\text{cda}} = 38\ \text{J}$, $E_{\text{int,a}} - E_{\text{int,b}} = \Delta E_{\substack{\text{int}\\\text{ba}}} = 15\,\text{J}$, and $P_{\text{a}} = 2.2P_{\text{d}}$.

(*a*) Use the first law of thermodynamics to find $E_{\text{int,a}} - E_{\text{int,c}} = \Delta E_{\text{ca}}$.

$$\Delta E_{\substack{\text{int}\\\text{ca}}} = -\Delta E_{\substack{\text{int}\\\text{ac}}} = -\left(Q_{\text{ac}} - W_{\text{ac}}\right) = -\left(-85\,\text{J} - -55\,\text{J}\right) = \boxed{30\,\text{J}}$$

(*b*) Use the first law of thermodynamics to find Q_{cda}.

$$\Delta E_{\substack{\text{int}\\\text{cda}}} = Q_{\text{cda}} - W_{\text{cda}} \rightarrow Q_{\text{cda}} = \Delta E_{\substack{\text{int}\\\text{cda}}} + W_{\text{cda}} = \Delta E_{\substack{\text{int}\\\text{ca}}} + W_{\text{cda}} = 30\ \text{J} + 38\ \text{J} = \boxed{68\,\text{J}}$$

(*c*) Since the work along path bc is 0, $W_{\text{abc}} = W_{\text{ab}} = P_{\text{a}}\Delta V_{\text{ab}} = P_{\text{a}}\left(V_{\text{b}} - V_{\text{a}}\right)$.

$$W_{\text{abc}} = W_{\text{ab}} = P_{\text{a}}\Delta V_{\text{ab}} = P_{\text{a}}\left(V_{\text{b}} - V_{\text{a}}\right) = 2.2P_{\text{d}}\left(V_{\text{c}} - V_{\text{d}}\right) = -2.2W_{\text{cda}} = -2.2\left(38\ \text{J}\right) = \boxed{-84\ \text{J}}$$

(*d*) Use the first law of thermodynamics to find Q_{abc}.

$$\Delta E_{\substack{\text{int}\\\text{abc}}} = Q_{\text{abc}} - W_{\text{abc}} \rightarrow Q_{\text{abc}} = \Delta E_{\substack{\text{int}\\\text{abc}}} + W_{\text{abc}} = \Delta E_{\substack{\text{int}\\\text{ac}}} + W_{\text{abc}} = -30\ \text{J} - 84\,\text{J} = \boxed{-114\ \text{J}}$$

(*e*) Since $E_{\text{int,a}} - E_{\text{int,b}} = 15\ \text{J} \rightarrow E_{\text{int,b}} = E_{\text{int,a}} - 15\ \text{J}$, we have the following.

$$\Delta E_{\substack{\text{int}\\\text{bc}}} = E_{\text{int,c}} - E_{\text{int,b}} = E_{\text{int,c}} - \left(E_{\text{int,a}} - 15\ \text{J}\right) = \Delta E_{\substack{\text{int}\\\text{ac}}} + 15\ \text{J} = -30\ \text{J} + 15\ \text{J} = -15\ \text{J}.$$

Use the first law of thermodynamics to find Q_{bc}.

$$\Delta E_{\substack{\text{int}\\\text{bc}}} = Q_{\text{bc}} - W_{\text{bc}} \rightarrow Q_{\text{bc}} = \Delta E_{\substack{\text{int}\\\text{bc}}} + W_{\text{bc}} = -15\ \text{J} + 0 = \boxed{-15\ \text{J}}$$

40. (*a*) Leg ba is an isobaric expansion, and so the work done is positive.
Leg ad is an isovolumetric reduction in pressure, and so the work done on that leg is 0.
Leg dc is an isobaric compression, and so the work done is negative.
Leg cb is an isovolumetric expansion in pressure, and so the work done on that leg is 0.

(*b*) From problem 38, $W_{\text{cda}} = W_{\text{cd}} + W_{\text{da}} = 38\,\text{J}$, so $W_{\text{adc}} = W_{\text{ad}} + W_{\text{dc}} = -38\,\text{J}$. Also from problem 38, $W_{\text{abc}} = -84\,\text{J}$, and so $W_{\text{cba}} = W_{\text{cb}} + W_{\text{ba}} = 84\,\text{J}$. So the net work done during the cycle is as follows.

$$W_{\text{net}} = W_{\text{ba}} + W_{\text{ad}} + W_{\text{dc}} + W_{\text{cb}} = 84\,\text{J} - 38\,\text{J} = \boxed{46\,\text{J}}$$

(*c*) Since the process is a cycle, the initial and final states are the same, and so the internal energy does not change.

$$\Delta E_{\text{int}} = \boxed{0}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*d*) Use the first law of thermodynamics, applied to the entire cycle.

$$\Delta E_{\substack{\text{int}\\\text{tot}}} = Q_{\text{net}} - W_{\text{net}} \quad \rightarrow \quad Q_{\text{net}} = \Delta E_{\text{int}} + W_{\text{net}} = 0 + 46\,\text{J} = \boxed{46\,\text{J}}$$

(*e*) From problem 39(*b*), we have $Q_{\text{adc}} = -68\,\text{J}$. This is the exhaust heat. So the input heat is found as follows.

$$Q_{\text{net}} = Q_{\text{acd}} + Q_{\text{dca}} = -68\,\text{J} + Q_{\text{dca}} = 46\,\text{J} \quad \rightarrow \quad Q_{\text{dca}} = 114\,\text{J} = Q_{\text{input}}$$

$$\text{efficiency} = \frac{W_{\text{net}}}{Q_{\text{input}}} \times 100 = \frac{46\,\text{J}}{114\,\text{J}} \times 100 = \boxed{40\%} \quad (2 \text{ sig. fig.})$$

41. The work is given by $W = \int_{V_1}^{V_2} P\,dV$. The pressure is given by the van der Waals expression, Eq. 18-9, with *n* = 1.00. The temperature is held constant. We will keep the moles as *n* until the last step.

$$W = \int_{V_1}^{V_2} P\,dV = \int_{V_1}^{V_2} \left(\frac{RT}{\frac{V}{n} - b} - \frac{a}{\left(\frac{V}{n}\right)^2} \right) dV = \int_{V_1}^{V_2} \left(\frac{nRT}{V - bn} - \frac{an^2}{V^2} \right) dV = \left[nRT \ln\left(V - bn\right) + \frac{an^2}{V} \right]_{V_1}^{V_2}$$

$$= \left[nRT \ln\left(V_2 - bn\right) + \frac{an^2}{V_2} \right] - \left[nRT \ln\left(V_1 - bn\right) + \frac{an^2}{V_1} \right] = nRT \ln \frac{\left(V_2 - bn\right)}{\left(V_1 - bn\right)} + an^2 \left(\frac{1}{V_2} - \frac{1}{V_1} \right)$$

We evaluate for *n* = 1.00 mol, to get $W = \boxed{RT \ln \frac{\left(V_2 - b\right)}{\left(V_1 - b\right)} + a\left(\frac{1}{V_2} - \frac{1}{V_1} \right)}$.

42. For a diatomic gas with all degrees of freedom active, the internal energy is given by $E_{\text{int}} = \frac{7}{2} nRT$.

$$E_{\text{int}} = \tfrac{7}{2} nRT = \tfrac{7}{2}\left(4.50\,\text{mol}\right)\left(8.314\,\text{J/mol•K}\right)\left(645\,\text{K}\right) = \boxed{8.45 \times 10^4\,\text{J}}$$

43. If there are no heat losses or mass losses, then the heating occurs at constant volume, and so Eq. 19-10a applies, $Q = nC_{\text{V}}\Delta T$. Air is primarily made of diatomic molecules, and for an ideal diatomic gas, $C_{\text{V}} = \frac{5}{2} R$.

$$Q = nC_{\text{V}}\Delta T = \tfrac{5}{2} nR\Delta T = \tfrac{5}{2} \frac{P_0 V_0}{T_0} \Delta T \quad \rightarrow$$

$$\Delta T = \frac{2QT}{5PV} = \frac{2\left(1.8 \times 10^6\,\text{J}\right)\left(293\,\text{K}\right)}{5\left(1.013 \times 10^5\,\text{Pa}\right)\left(3.5\,\text{m}\right)\left(4.6\,\text{m}\right)\left(3.0\,\text{m}\right)} = 43.12\,\text{K} \approx \boxed{43\text{C}^\circ}$$

44. For one mole of gas, each degree of freedom has an average energy of $\frac{1}{2} RT$, so the internal energy of a mole of the gas is as follows.

$$E_{\text{int}} = n\left(\tfrac{1}{2} RT\right) = C_V T \quad \rightarrow \quad C_V = \boxed{\tfrac{1}{2} nR}$$

$$C_P = C_V + R = \frac{n}{2} R + R = \frac{n}{2} R + \frac{2}{2} R = \boxed{\tfrac{1}{2}\left(n + 2\right) R}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

45. Since the gas is monatomic, the molar specific heat is given by $C_V = \frac{3}{2}R$. The molar specific heat is also given by $C_V = Mc_V$, where *M* is the molecular mass. Equate these two expressions to find the molecular mass and the identity of the gas.

$$C_V = \tfrac{3}{2}R = Mc_V \quad \rightarrow \quad M = \frac{3R}{2c_V} = \frac{3(8.314\,\text{J/mol•K})}{2(0.0356\,\text{kcal/kg•C°})}\frac{1\,\text{kcal}}{4186\,\text{J}}\frac{1000\,\text{g}}{1\,\text{kg}} = \boxed{83.7\,\text{g/mol}}$$

From the periodic table, we see that the gas is krypton, which has a molecular mass of 83.6 g/mol.

46. The process is adiabatic, and so the heat transfer is 0. Apply the first law of thermodynamics.

$$\Delta E_{\text{int}} = Q - W = 0 - W \quad \rightarrow \quad W = -\Delta E_{\text{int}} = -nC_V\Delta T = nC_V(T_1 - T_2)$$

47. If there are no heat losses, and no work being done, then the heat due to the people will increase the internal energy of the air, as given in Eq. 19-12. Note that air is basically diatomic. Use the ideal gas equation to estimate the number of moles of air, assuming the room is initially at 293 K.

$$Q = \Delta E_{\text{int}} = nC_V\Delta T \;\; ; \;\; n = \frac{PV}{RT} \quad \rightarrow$$

$$\Delta T = \frac{Q}{nC_V} = \frac{Q}{\frac{P_0V_0}{RT_0}C_V} = \frac{RT_0Q}{P_0V_0C_V} = \frac{RT_0Q}{P_0V_0\frac{5}{2}R} = \frac{2T_0Q}{5P_0V_0}$$

$$= \frac{2(293\,\text{K})\left[(1800\,\text{people})\left(\frac{70\,\text{W}}{\text{person}}\right)(7200\,\text{s})\right]}{5(1.013\times10^5\,\text{Pa})(2.2\times10^4\,\text{m}^3)} = 47.7\,\text{K} \approx \boxed{48\,\text{C°}}$$

48. (*a*) First find the molar specific heat at constant volume, then the molar specific heat at constant pressure, and then finally the specific heat at constant pressure.

$$C_V = Mc_V = (0.034\,\text{kg/mol})(0.182\,\text{kcal/kg•K})\left(\frac{10^3\,\text{cal}}{1\,\text{kcal}}\right) = 6.188\,\text{cal/mol•K}$$

$$c_P = \frac{C_P}{M} = \frac{C_V + R}{M} = \frac{(6.188\,\text{cal/mol•K}) + (1.99\,\text{cal/mol•K})}{(0.034\,\text{kg/mol})}\left(\frac{1\,\text{kcal}}{10^3\,\text{cal}}\right) = \boxed{0.241\,\text{kcal/kg•K}}$$

(*b*) From the value for $C_V = 6.188\,\text{cal/mol•K}$, we see from Table 19-4 that this gas is probably triatomic.

49. (*a*) The change in internal energy is given by Eq. 19-12. The nitrogen is diatomic.

$$\Delta E_{\text{int}} = nC_V\Delta T = n\left(\tfrac{5}{2}R\right)\Delta T = \tfrac{5}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol•K}}\right)(150\,\text{K}) = 6236\,\text{J} \approx \boxed{6240\,\text{J}} \text{ or}$$

$$\Delta E_{\text{int}} = nC_V\Delta T = (2.00\,\text{mol})\left(4.96\frac{\text{cal}}{\text{mol•K}}\right)\left(4.186\frac{\text{J}}{\text{cal}}\right)(150\,\text{K}) = 6229\,\text{J} \approx \boxed{6230\,\text{J}}$$

(*b*) The work is done at constant pressure.

$$W = P\Delta V = nR\Delta T = (2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol•K}}\right)(150\,\text{K}) = 2494\,\text{J} \approx \boxed{2490\,\text{J}}$$

(*c*) The heat is added at constant pressure, and so Eq. 19-10b applies.

$$Q = nC_p\Delta T = n\left(\tfrac{7}{2}R\right)\Delta T = \tfrac{7}{2}(2.00\,\text{mol})\left(8.314\frac{\text{J}}{\text{mol•K}}\right)(150\,\text{K}) = \boxed{8730\,\text{J}} \text{ or}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\Delta E_{\text{int}} = Q - W \;\rightarrow\; Q = \Delta E_{\text{int}} + W = 6229\,\text{J} + 2494\,\text{J} = \boxed{8720\,\text{J}}$$

50. (*a*) The change in internal energy is given by Eq. 19-12.

$$\Delta E_{\text{int}} = nC_V\Delta T = n\left(\tfrac{5}{2}R\right)\Delta T = \tfrac{5}{2}(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(300\,\text{K}) = \boxed{6240\,\text{J}}$$

(*b*) The work is given by $W = \int PdV$. The pressure is a linear function of temperature, so $P = P_0 + aT$. Use the given data to find the constants P_0 and a. Use the ideal gas equation to express the integral in terms of pressure.

$$1.60\,\text{atm} = P_0 + a(720\,\text{K})\;;\; 1.00\,\text{atm} = P_0 + a(420\,\text{K}) \;\rightarrow$$

$$(1.60\,\text{atm} - 1.00\,\text{atm}) = [P_0 + a(720\,\text{K})] - P_0 + a(420\,\text{K}) = a(300\,\text{K}) \;\rightarrow$$

$$a = \frac{0.60\,\text{atm}}{300\,\text{K}} = 2.0\times10^{-3}\,\text{atm/K}\;\;;\;\; P_0 = 1.60\,\text{atm} - \left(2.0\times10^{-3}\,\text{atm/K}\right)(720\text{K}) = -0.16\,\text{atm}$$

$$PV = nRT \;\rightarrow\; V = \frac{nRT}{P} = \frac{nR}{P}\frac{(P-P_0)}{a} = \frac{nR}{a}\left(1 - \frac{P_0}{P}\right) \;\rightarrow\; dV = \frac{nR}{a}\frac{P_0}{P^2}dP$$

$$W = \int_{V_1}^{V_2} PdV = \int_{P_1}^{P_2} P\frac{nR}{a}\frac{P_0}{P^2}dP = \frac{nRP_0}{a}\int_{P_1}^{P_2}\frac{1}{P}dP = \frac{nRP_0}{a}\ln\left(\frac{P_2}{P_1}\right)$$

$$= \frac{(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(-0.16\,\text{atm})}{2.0\times10^{-3}\,\text{atm/K}}\ln\left(\frac{1.60\,\text{atm}}{1.00\,\text{atm}}\right) = \boxed{-310\,\text{J}}$$

(*c*) Use the first law of thermodynamics.

$$\Delta E_{\text{int}} = Q - W \;\rightarrow\; Q = \Delta E_{\text{int}} + W = 6240\,\text{J} - 310\,\text{J} = \boxed{5930\,\text{J}}$$

51. For a diatomic gas with no vibrational modes excited, we find the γ parameter.

$$\gamma = \frac{C_P}{C_V} = \frac{C_V + R}{C_V} = \frac{\frac{5}{2}R + R}{\frac{5}{2}R} = \tfrac{7}{5}$$

For an adiabatic process, we have $PV^\gamma = \text{constant}$. Use this to find the final pressure.

$$P_1V_1^\gamma = P_2V_2^\gamma \;\rightarrow\; P_2 = P_1\left(\frac{V_1}{V_2}\right)^\gamma = (1.00\,\text{atm})\left(\frac{1}{1.75}\right)^{1.4} = 0.4568\,\text{atm} \approx \boxed{0.457\,\text{atm}}$$

Use the ideal gas law to find the final temperature.

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \;\rightarrow\; T_2 = T_1\left(\frac{P_2}{P_1}\right)\left(\frac{V_2}{V_1}\right) = (293\,\text{K})(0.4568)(1.75) = 234\,\text{K} = \boxed{-39°\text{C}}$$

52. The work is given by $W = \int_{V_1}^{V_2} PdV$. The pressure is given by the adiabatic condition, $PV^\gamma = c$, where c is a constant. Note that for the two states given, $c = P_1V_1^\gamma = P_2V_2^\gamma$

$$W = \int_{V_1}^{V_2} PdV = \int_{V_1}^{V_2}\frac{c}{V^\gamma}dV = \frac{cV^{1-\gamma}}{1-\gamma}\bigg|_{V_1}^{V_2} = \frac{\left(cV_2^{1-\gamma} - cV_1^{1-\gamma}\right)}{1-\gamma} = \frac{\left(P_2V_2^\gamma V_2^{1-\gamma} - P_1V_1^\gamma V_1^{1-\gamma}\right)}{1-\gamma} = \boxed{\frac{(P_1V_1 - P_2V_2)}{\gamma - 1}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

53. (*a*) We first find the final pressure from the adiabatic relationship, and then use the ideal gas law to find the temperatures. For a diatomic gas, $\gamma = 1.4$.

$$P_1V_1^{\gamma} = P_2V_2^{\gamma} \quad \rightarrow \quad P_2 = P_1\left(\frac{V_1}{V_2}\right)^{\gamma} = (1.00\,\text{atm})\left(\frac{0.1210\,\text{m}^3}{0.750\,\text{m}^3}\right)^{1.4} = 7.772\times10^{-2}\,\text{atm}$$

$$PV = nRT \quad \rightarrow \quad T = \frac{PV}{nR} \qquad T_1 = \frac{P_1V_1}{nR} = \frac{(1.013\times10^5\,\text{Pa})(0.1210\,\text{m}^3)}{(3.65\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)} = 403.9\,\text{K} \approx \boxed{404\,\text{K}}$$

$$T_2 = \frac{P_2V_2}{nR} = \frac{(7.772\times10^{-2})(1.013\times10^5\,\text{Pa})(0.750\,\text{m}^3)}{(3.65\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)} = 194.6\,\text{K} \approx \boxed{195\,\text{K}}$$

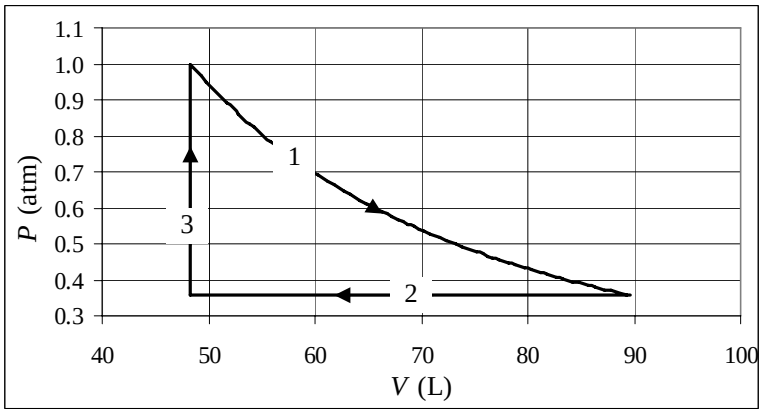
(*b*) $\Delta E_{\text{int}} = nC_C\Delta T = n\left(\frac{5}{2}R\right)\Delta T = (3.65\,\text{mol})\frac{5}{2}\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(194.6\,\text{K} - 403.9\,\text{K}) = \boxed{-1.59\times10^4\,\text{J}}$

(*c*) Since the process is adiabatic, no heat is transferred. $\boxed{Q = 0}$

(*d*) Use the first law of thermodynamics to find the work done by the gas. The work done ON the gas is the opposite of the work done BY the gas.

$$\Delta E_{\text{int}} = Q - W \quad \rightarrow \quad W = Q - \Delta E_{\text{int}} = 0 - (-1.59\times10^4\,\text{J}) = 1.59\times10^4\,\text{J}$$

$$W_{\substack{\text{on}\\\text{gas}}} = \boxed{-1.59\times10^4\,\text{J}}$$



54. Combine the ideal gas equation with Eq. 19-15 for adiabatic processes.

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \quad \rightarrow \quad \frac{P_1}{P_2} = \frac{V_2}{V_1}\frac{T_1}{T_2} \quad ; \quad P_1V_1^{\gamma} = P_2V_2^{\gamma} \quad \rightarrow \quad \frac{P_1}{P_2} = \frac{V_2^{\gamma}}{V_1^{\gamma}}$$

$$\gamma = \frac{C_P}{C_V} = \frac{C_V + R}{C_V} = \frac{\frac{3}{2}R + R}{\frac{3}{2}R} = \frac{5}{3}$$

$$\frac{V_2}{V_1}\frac{T_1}{T_2} = \frac{V_2^{\gamma}}{V_1^{\gamma}} \quad \rightarrow \quad V_2^{\gamma-1} = V_1^{\gamma-1}\left(\frac{T_1}{T_2}\right) \quad \rightarrow \quad V_2 = V_1\left(\frac{T_1}{T_2}\right)^{\frac{1}{\gamma-1}} = (0.086\,\text{m}^3)\left(\frac{273\,\text{K} + 25\,\text{K}}{273\,\text{K} - 68\,\text{K}}\right)^{3/2} = \boxed{0.15\,\text{m}^3}$$

55. (*a*) To plot the graph accurately, data points must be calculated. V_1 is found from the ideal gas equation, and P_2 and V_2 are found from the fact that the first expansion is adiabatic. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH19.XLS," on tab "Problem 19.55a."

$$P_1V_1 = nRT_1 \;\rightarrow\; V_1 = \frac{nRT_1}{P_1} = \frac{(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(588\,\text{K})}{1.013\times10^5\,\text{Pa}} = 48.26\times10^{-3}\,\text{m}^3 = 48.26\,\text{L}$$

$$P_2V_2 = nRT_2\ ,\ P_2V_2^{\gamma} = P_1V_1^{\gamma} \;\rightarrow\; V_2^{\gamma-1} = \frac{P_1V_1^{\gamma}}{nRT_2} \;\rightarrow$$

$$V_2 = \left(\frac{P_1V_1^{5/3}}{nRT_2}\right)^{3/2} = \left(\frac{\left(1.013\times10^5\,\text{Pa}\right)\left(48.26\times10^{-3}\,\text{m}^3\right)^{5/3}}{(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(389\,\text{K})}\right)^{3/2} = 89.68\times10^{-3}\,\text{m}^3 = 89.68\,\text{L}$$

$$P_2 = \frac{nRT_2}{V_2} = \frac{(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(389\,\text{K})}{89.68\times10^{-3}\,\text{m}^3} = 3.606\times10^4\,\text{Pa}\left(\frac{1\,\text{atm}}{1.013\times10^5\,\text{Pa}}\right) = 0.356\,\text{atm}$$

(*b*) Both the pressure and the volume are known at the lower left corner of the graph.

$$P_3 = P_2\ ,\ V_3 = V_1 \;\rightarrow\; P_3V_3 = nRT_3 \;\rightarrow$$

$$T_3 = \frac{P_3V_3}{nR} = \frac{P_2V_1}{nR} = \frac{\left(3.606\times10^4\,\text{Pa}\right)\left(48.26\times10^{-3}\,\text{m}^3\right)}{(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)} = \boxed{209\,\text{K}}$$

(*c*) For the adiabatic process, state 1 to state 2:

$$\Delta E_{\text{int}} = \tfrac{3}{2}nR\Delta T = \tfrac{3}{2}(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(389\,\text{K} - 588\,\text{K}) = -2482\,\text{J} \approx \boxed{-2480\,\text{J}}$$

$$Q = \boxed{0}\ \text{(adiabatic)}\ ;\ W = Q - \Delta E_{\text{int}} = \boxed{2480\,\text{J}}$$

For the constant pressure process, state 2 to state 3:

$$\Delta E_{\text{int}} = \tfrac{3}{2}nR\Delta T = \tfrac{3}{2}(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(209\,\text{K} - 389\,\text{K}) = -2244.7\,\text{J} \approx \boxed{-2240\,\text{J}}$$

$$W = P\Delta V = \left(3.606\times10^4\,\text{Pa}\right)\left(48.26\times10^{-3}\,\text{m}^3 - 89.68\times10^{-3}\,\text{m}^3\right) = -1494\,\text{J} \approx \boxed{-1490\,\text{J}}$$

$$Q = W + \Delta E_{\text{int}} = -1494\,\text{J} - 2244.7\,\text{J} = -3739\,\text{J} \approx \boxed{-3740\,\text{J}}$$

For the constant volume process, state 3 to state 1:

$$\Delta E_{\text{int}} = \tfrac{3}{2}nR\Delta T = \tfrac{3}{2}(1.00\,\text{mol})\left(8.314\,\frac{\text{J}}{\text{mol}\bullet\text{K}}\right)(588\,\text{K} - 209\,\text{K}) = 4727\,\text{J} \approx \boxed{4730\,\text{J}}$$

$$W = P\Delta V = 0\ ;\ Q = W + \Delta E_{\text{int}} = \boxed{4730\,\text{J}}$$

(*d*) For the complete cycle, by definition $\Delta E_{\text{int}} = \boxed{0}$. If the values from above are added, we get $\Delta E_{\text{int}} = 4727\,\text{J} - 2482\,\text{J} - 2245\text{J} = 0$. Add the separate values for the work done and the heat added.

$$W = 2482\,\text{J} - 1494\,\text{J} = 998\,\text{J} \approx \boxed{990\,\text{J}}\ ;\ Q = -3739\,\text{J} + 4727\,\text{J} = 998\,\text{J} \approx \boxed{990\,\text{J}}$$

Notice that the first law of thermodynamics is satisfied.

56. (*a*) Combine the ideal gas law with Eq. 19-15 for adiabatic processes.

$$PV = nRT \;\rightarrow\; V = \frac{nRT}{P} \;;\; PV^\gamma = \text{constant} = P\left(\frac{nRT}{P}\right)^\gamma = P^{1-\gamma}T^\gamma (nR)^\gamma \;\rightarrow$$

$$P^{1-\gamma}T^\gamma = \frac{\text{constant}}{(nR)^\gamma}$$

But since *n* and *R* are constant for a fixed amount of gas, we have $\boxed{P^{1-\gamma}T^\gamma = \text{constant}}$.

Take the derivative of the above expression with respect to *y*, using the product rule and chain rule.

$$P^{1-\gamma}T^\gamma = \text{constant} \;\rightarrow\; \frac{d}{dy}\left(P^{1-\gamma}T^\gamma\right) = \frac{d}{dy}(\text{constant}) = 0 \;\rightarrow$$

$$T^\gamma (1-\gamma) P^{-\gamma}\frac{dP}{dy} + P^{1-\gamma}\gamma T^{\gamma-1}\frac{dT}{dy} = 0$$

Multiply this equation by P^γ / T^γ.

$$\frac{P^\gamma}{T^\gamma}\left[T^\gamma (1-\gamma) P^{-\gamma}\frac{dP}{dy} + P^{1-\gamma}\gamma T^{\gamma-1}\frac{dT}{dy}\right] = \boxed{(1-\gamma)\frac{dP}{dy} + \gamma\frac{P}{T}\frac{dT}{dy} = 0}$$

We also assume that $\frac{dP}{dy} = -\rho g,$ and so get the following.

$$\boxed{(1-\gamma)(-\rho g) + \gamma\frac{P}{T}\frac{dT}{dy} = 0}, \text{ or } \frac{dT}{dy} = \frac{(1-\gamma)}{\gamma}\frac{T}{P}\rho g$$

(*b*) Use the ideal gas law. We let *M* represent the total mass of the gas and *m* represent the mass of one molecule, so $N = \frac{M}{m}$. The density of the gas is $\rho = \frac{M}{V}$.

$$PV = NkT \;\rightarrow\; \frac{T}{P} = \frac{V}{Nk} = \frac{Vm}{Mk} = \frac{m}{\rho k} \;\rightarrow$$

$$\frac{dT}{dy} = \frac{(1-\gamma)}{\gamma}\frac{T}{P}\rho g = \frac{(1-\gamma)}{\gamma}\left(\frac{m}{\rho k}\right)\rho g = \boxed{\frac{(1-\gamma)}{\gamma}\frac{mg}{k}}$$

(*c*) For a diatomic ideal gas, $\gamma = \frac{7}{5}$.

$$\frac{dT}{dy} = \frac{(1-\gamma)}{\gamma}\frac{mg}{k} = \frac{(1-\frac{7}{5})}{\frac{7}{5}}\frac{29\left(1.66\times10^{-27}\,\text{kg}\right)\left(9.80\,\text{m/s}^2\right)}{1.38\times10^{-23}\,\text{J/K}} = -9.77\times10^{-3}\,\text{K/m}$$

$$= \left(-9.77\times10^{-3}\,\text{K/m}\right)\left(\frac{10^3\,\text{m}}{1\,\text{km}}\right)\left(\frac{1\,\text{C°}}{1\,\text{K}}\right) = -9.77\,\text{C°/km} \approx \boxed{-9.8\,\text{C°/km}}$$

(*d*) $\Delta T = \frac{dT}{dy}\Delta y = \left(-9.77\,\text{C°/km}\right)\left(-0.1\,\text{km} - 4.0\,\text{km}\right) = 40\,\text{C°} = T_f - (-5°\text{C}) \;\rightarrow\; T_f = \boxed{35°\text{C}} \approx 95°\text{F}$

57. (*a*) The power radiated is given by Eq. 19-17. The temperature of the tungsten is $273\,\text{K} + 25\,\text{K} = 298\,\text{K}$.

$$\frac{\Delta Q}{\Delta t} = e\sigma AT^4 = (0.35)\left(5.67\times10^{-8}\,\text{W/m}^2\text{•K}^4\right)4\pi(0.16\,\text{m})^2(298\,\text{K})^4 = \boxed{50\,\text{W}} \;(2\text{ sig. fig.})$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The net power is given by Eq. 19-18. The temperature of the surroundings is 268 K.

$$\frac{\Delta Q}{\Delta t} = e\sigma A\left(T_1^4 - T_1^4\right) = (0.35)\left(5.67\times10^{-8}\ \text{W/m}^2\text{•K}^4\right)4\pi(0.16\,\text{m})^2\left[(298\,\text{K})^4 - (268\,\text{K})^4\right]$$

$$= \boxed{17\,\text{W}}$$

58. The heat conduction rate is given by Eq. 19-16a.

$$\frac{Q}{t} = kA\frac{T_1 - T_2}{\ell} = (380\,\text{J/s•m•C°})\pi(0.010\,\text{m})^2\frac{(460°\text{C} - 22°\text{C})}{0.45\,\text{m}} = 116\,\text{W} \approx \boxed{120\,\text{W}}$$

59. Eq. 19-19 gives the heat absorption rate for an object facing the Sun. The heat required to melt the ice is the mass of the ice times the latent heat of fusion for the ice. The mass is found by multiplying the volume of ice times its density.

$$\Delta Q = mL_f = \rho V L_f = \rho A(\Delta x)L_f \qquad \frac{\Delta Q}{\Delta t} = \left(1000\,\text{W/m}^2\right)eA\cos\theta \ \rightarrow$$

$$\Delta t = \frac{\rho A(\Delta x)L_f}{\left(1000\,\text{W/m}^2\right)eA\cos\theta} = \frac{\rho(\Delta x)L_f}{\left(1000\,\text{W/m}^2\right)e\cos\theta}$$

$$= \frac{\left(9.17\times10^2\ \text{kg/m}^3\right)\left(1.0\times10^{-2}\,\text{m}\right)\left(3.33\times10^5\ \text{J/kg}\right)}{\left(1000\,\text{W/m}^2\right)(0.050)\cos35°} = \boxed{7.5\times10^4\,\text{s}} \approx 21\,\text{h}$$

60. The distance can be calculated from the heat conduction rate, given by Eq. 19-16a. The rate is given as a power (150 W = 150 J/s).

$$\frac{Q}{t} = P = kA\frac{T_1 - T_2}{\ell} \ \rightarrow \ \ell = kA\frac{T_1 - T_2}{P} = (0.2\,\text{J/s•m•C°})\left(1.5\ \text{m}^2\right)\frac{0.50\,\text{C°}}{150\,\text{W}} = \boxed{1.0\times10^{-3}\,\text{m}}$$

61. (*a*) The rate of heat transfer due to radiation is given by Eq. 19-17. We assume that each teapot is a sphere that holds 0.55 L. The radius and then the surface area can be found from that.

$$V = \tfrac{4}{3}\pi r^3 \ \rightarrow \ r = \left(\frac{3V}{4\pi}\right)^{1/3} \ \rightarrow \ S.A. = 4\pi r^2 = 4\pi\left(\frac{3V}{4\pi}\right)^{2/3}$$

$$\frac{\Delta Q}{\Delta t} = \varepsilon\sigma A\left(T_1^4 - T_2^4\right) = 4\pi\varepsilon\sigma\left(\frac{3V}{4\pi}\right)^{2/3}\left(T_1^4 - T_2^4\right)$$

$$\left(\frac{\Delta Q}{\Delta t}\right)_{\text{ceramic}} = 4\pi(0.70)\left(5.67\times10^{-8}\,\frac{\text{W}}{\text{m}^2\text{•K}^4}\right)\left(\frac{3\left(0.55\times10^{-3}\,\text{m}^2\right)}{4\pi}\right)^{2/3}\left[(368\,\text{K})^4 - (293\,\text{K})^4\right]$$

$$= 14.13\text{W} \approx \boxed{14\,\text{W}}$$

$$\left(\frac{\Delta Q}{\Delta t}\right)_{\text{shiny}} = \left(\frac{\Delta Q}{\Delta t}\right)_{\text{ceramic}}\left(\frac{0.10}{0.70}\right) = 2.019\,\text{W} \approx \boxed{2.0\,\text{W}}$$

(*b*) We assume that the heat capacity comes primarily from the water in the teapots, and ignore the heat capacity of the teapots themselves. We apply Eq. 19-2, along with the results from part (*a*). The mass is that of 0.55 L of water, which would be 0.55 kg.

$$\Delta Q = mc\Delta T \ \rightarrow \ \Delta T = \frac{1}{mc}\left(\frac{\Delta Q}{\Delta t}\right)_{\text{radiation}}\Delta t_{\text{elapsed}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$(\Delta T)_{\text{ceramic}} = \frac{14.13\,\text{W}}{(0.55\,\text{kg})\left(4186\dfrac{\text{J}}{\text{kg}\bullet\text{C}^\circ}\right)}(1800\,\text{s}) = \boxed{11\text{C}^\circ}$$

$$(\Delta T)_{\text{shiny}} = \frac{1}{7}(\Delta T)_{\text{ceramic}} = \boxed{1.6\text{C}^\circ}$$

62. For the temperature at the joint to remain constant, the heat flow in both rods must be the same. Note that the cross-sectional areas and lengths are the same. Use Eq. 19-16a for heat conduction.

$$\left(\frac{Q}{t}\right)_{\text{Cu}} = \left(\frac{Q}{t}\right)_{\text{Al}} \quad \rightarrow \quad k_{\text{Cu}}A\frac{T_{\text{hot}} - T_{\text{middle}}}{\ell} = k_{\text{Al}}A\frac{T_{\text{middle}} - T_{\text{cool}}}{\ell} \quad \rightarrow$$

$$T_{\text{middle}} = \frac{k_{\text{Cu}}T_{\text{hot}} + k_{\text{Al}}T_{\text{cool}}}{k_{\text{Cu}} + k_{\text{Al}}} = \frac{(380\,\text{J/s}\bullet\text{m}\bullet\text{C}^\circ)(225^\circ\text{C}) + (200\,\text{J/s}\bullet\text{m}\bullet\text{C}^\circ)(0.0^\circ\text{C})}{380\,\text{J/s}\bullet\text{m}\bullet\text{C}^\circ + 200\,\text{J/s}\bullet\text{m}\bullet\text{C}^\circ} = \boxed{147^\circ\text{C}}$$

63. (*a*) The cross-sectional area of the Earth, perpendicular to the Sun, is a circle of radius R_{Earth}, and so has an area of πR_{Earth}^2. Multiply this area times the solar constant to get the rate at which the Earth is receiving solar energy.

$$\frac{Q}{t} = \pi R_{\text{Earth}}^2\,(\text{solar constant}) = \pi\left(6.38\times10^6\,\text{m}\right)^2\left(1350\,\text{W/m}^2\right) = \boxed{1.73\times10^{17}\,\text{W}}$$

(*b*) Use Eq. 19-18 to calculate the rate of heat output by radiation, and assume that the temperature of space is 0 K. The whole sphere is radiating heat back into space, and so we use the full surface area of the Earth, $4\pi R_{\text{Earth}}^2$.

$$\frac{Q}{t} = e\sigma AT^4 \quad \rightarrow \quad T = \left(\frac{Q}{t}\frac{1}{\varepsilon\sigma A}\right)^{1/4}$$

$$= \left[\left(1.73\times10^{17}\,\text{J/s}\right)\frac{1}{(1.0)\left(5.67\times10^{-8}\,\text{W/m}^2\bullet\text{K}^4\right)4\pi\left(6.38\times10^6\,\text{m}\right)^2}\right]^{1/4} = \boxed{278\,\text{K} = 5^\circ\text{C}}$$

64. This is an example of heat conduction. The temperature difference can be calculated by Eq. 19-16a.

$$\frac{Q}{t} = P = kA\frac{T_1 - T_2}{\ell} \quad \rightarrow \quad \Delta T = \frac{P\ell}{kA} = \frac{(95\,\text{W})\left(5.0\times10^{-4}\,\text{m}\right)}{\left(0.84\,\text{J/s}\bullet\text{m}\bullet\text{C}^\circ\right)4\pi\left(3.0\times10^{-2}\,\text{m}\right)^2} = \boxed{5.0\text{C}^\circ}$$

65. We model the heat loss as conductive, so that, using Eq. 19-16a, $\frac{Q}{t} = \frac{kA}{\ell}\Delta T \quad \rightarrow \quad Q = \alpha t\Delta T$, where α describes the average heat conductivity properties of the house, such as insulation materials and surface area of the conducting surfaces. It could have units of $\text{J/h}\bullet^\circ\text{C}$. We see that the heat loss is proportional to the product of elapsed time and the temperature difference. We assume that the proportionality constant α does not vary during the day, so that, for example, heating by direct sunlight through windows is not considered. We also assume that α is independent of temperature, and so is the same during both the day and the night.

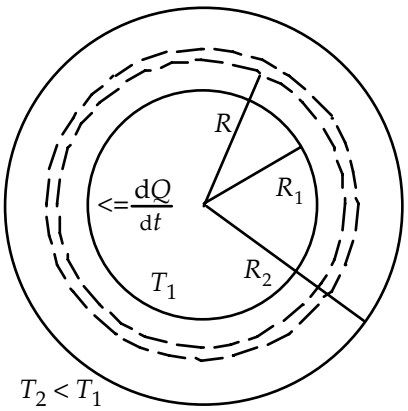
$$Q_{\substack{\text{turning}\\\text{down}}} = (\alpha\,\text{J/h}\bullet\text{C}^\circ)(15\,\text{h})(22^\circ\text{C} - 8^\circ\text{C}) + (\alpha\,\text{J/h}\bullet\text{C}^\circ)(9\,\text{h})(12^\circ\text{C} - 0^\circ\text{C}) = 318\alpha\,\text{J}$$

$$Q_{\substack{\text{not turning}\\\text{down}}} = (\alpha\,\text{J/h}\bullet\text{C}^\circ)(15\,\text{h})(22^\circ\text{C} - 8^\circ\text{C}) + (\alpha\,\text{J/h}\bullet\text{C}^\circ)(9\,\text{h})(22^\circ\text{C} - 0^\circ\text{C}) = 408\alpha\,\text{J}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{\Delta Q}{Q_{\substack{\text{turning}\\ \text{down}}}} = \frac{408\alpha\,\text{J} - 318\alpha\,\text{J}}{318\alpha\,\text{J}} = 0.28 = \boxed{28\%}$$

To keep the thermostat "up" requires about 28% more heat in this model than turning it down.



66. This is an example of heat conduction. The heat conducted is the heat released by the melting ice, $Q = m_{\text{ice}} L_{\text{fusion}}$. The area through which the heat is conducted is the total area of the six surfaces of the box, and the length of the conducting material is the thickness of the Styrofoam. We assume that all of the heat conducted into the box goes into melting the ice, and none into raising the temperature inside the box. The time can then be calculated by Eq. 19-16a.

$$\frac{Q}{t} = kA\frac{T_1 - T_2}{\ell} \quad \rightarrow \quad t = \frac{Q\ell}{kA\Delta T} = \frac{m_{\text{ice}} L_{\text{fusion}} \ell}{kA\Delta T}$$

$$= \frac{(9.5\text{ kg})\left(3.33\times10^5\text{ J/kg}\right)(0.015\text{m})}{2\left(0.023\text{J/s•m•C°}\right)\left[2(0.25\text{m})(0.35\text{m}) + 2(0.25\text{m})(0.55\text{m}) + 2(0.35\text{m})(0.55\text{m})\right](34\text{C°})}$$

$$= \boxed{3.6\times10^4\text{s}} \approx 10\text{h}$$

67. (*a*) Choose a cylindrical shell of length ℓ, radius R, and thickness dR. Apply Eq. 19-16b, modified for the radial geometry. See the figure. Note that $\frac{dQ}{dt}$ must be a constant, so that all of the heat energy that enters a shell also exits that shell.

$$\frac{dQ}{dt} = -kA\frac{dT}{dR} = -k2\pi R\ell\frac{dT}{dR} \quad \rightarrow$$

$$\frac{dR}{R} = -\frac{2\pi k\ell}{dQ/dt}dT \quad \rightarrow \quad \int_{R_1}^{R_2}\frac{dR}{R} = -\frac{2\pi k\ell}{dQ/dt}\int_{T_1}^{T_2}dT \quad \rightarrow$$

$$\ln\frac{R_2}{R_1} = \frac{2\pi k\ell}{dQ/dt}(T_1 - T_2) \quad \rightarrow \quad \boxed{\frac{dQ}{dt} = \frac{2\pi k(T_1 - T_2)\ell}{\ln(R_2/R_1)}}$$

(*b*) For still water, the initial heat flow outward from the water is described by Eq. 19-2.

$$\Delta Q = mc\Delta T \quad \rightarrow \quad \frac{\Delta Q}{\Delta t} = mc\frac{\Delta T}{\Delta t} = \frac{2\pi k(T_1 - T_2)\ell}{\ln(R_2/R_1)} \quad \rightarrow$$

$$\frac{\Delta T}{\Delta t} = \frac{2\pi k(T_1 - T_2)\ell}{mc\ln(R_2/R_1)} = \frac{2\pi k(T_1 - T_2)\ell}{\rho_{\text{H}_2\text{O}}\pi R_1^2\ell c\ln(R_2/R_1)} = \frac{2k(T_1 - T_2)}{\rho_{\text{H}_2\text{O}}R_1^2 c\ln(R_2/R_1)}$$

$$= \frac{2\left(40\dfrac{\text{J}}{\text{s•m•C°}}\right)(71°\text{C} - 18°\text{C})}{\left(1.0\times10^3\text{ kg/m}^3\right)(0.033\text{m})^2\left(4186\dfrac{\text{J}}{\text{kg•C°}}\right)\ln\left(\dfrac{4.0}{3.3}\right)} = 4.835\text{C°/s} \approx \boxed{4.8\text{C°/s}}$$

Note that this will lower the value of T_1, which would lower the rate of temperature change as time elapses.

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) The water at the entrance is losing temperature at a rate of $4.835\,\text{C}^\circ/\text{s}$. In one second, it will have traveled 8 cm, and so the temperature drop per cm is $\left(4.835\dfrac{\text{C}^\circ}{\text{s}}\right)\left(\dfrac{1\text{s}}{8\,\text{cm}}\right) = \boxed{0.60\,\text{C}^\circ/\text{cm}}$.

68. The conduction rates through the two materials must be equal. If they were not, the temperatures in the materials would be changing. Call the temperature at the boundary between the materials T_x.

$$\frac{Q}{t} = k_1 A\frac{T_1 - T_x}{\ell_1} = k_2 A\frac{T_x - T_2}{\ell_2} \quad \rightarrow \quad \frac{Q}{t}\frac{\ell_1}{k_1 A} = T_1 - T_x \;;\; \frac{Q}{t}\frac{\ell_2}{k_2 A} = T_x - T_2$$

Add these two equations together, and solve for the heat conduction rate.

$$\frac{Q}{t}\frac{\ell_1}{k_1 A} + \frac{Q}{t}\frac{\ell_2}{k_2 A} = T_1 - T_x + T_x - T_2 \quad \rightarrow \quad \frac{Q}{t}\left(\frac{\ell_1}{k_1} + \frac{\ell_2}{k_2}\right)\frac{1}{A} = T_1 - T_2 \quad \rightarrow$$

$$\frac{Q}{t} = A\frac{(T_1 - T_2)}{\left(\dfrac{\ell_1}{k_1} + \dfrac{\ell_2}{k_2}\right)} = A\frac{(T_1 - T_2)}{(R_1 + R_2)}$$

The *R*-value for the brick needs to be calculated, using the definition of *R* given on page 517.

$$R = \frac{\ell}{k} = \frac{4\,\text{in}}{0.84\dfrac{\text{J}}{\text{s}\bullet\text{m}\bullet\text{C}^\circ}}\frac{\left(\dfrac{1\,\text{ft}}{12\,\text{in}}\right)}{\left(\dfrac{1\,\text{Btu}}{1055\,\text{J}}\right)\left(\dfrac{1\,\text{m}}{3.281\,\text{ft}}\right)\left(\dfrac{5\,\text{C}^\circ}{9\,\text{F}^\circ}\right)\left(\dfrac{3600\,\text{s}}{1\,\text{h}}\right)} = 0.69\,\text{ft}^2\bullet\text{h}\bullet\text{F}^\circ/\text{Btu}$$

$$\frac{Q}{t} = A\frac{(T_1 - T_2)}{(R_1 + R_2)} = (195\,\text{ft}^2)\frac{(12\,\text{F}^\circ)}{(0.69 + 19)\,\text{ft}^2\bullet\text{h}\bullet\text{F}^\circ/\text{Btu}} = 119\,\text{Btu/h} \approx \boxed{120\,\text{Btu/h}}$$

This is about 35 Watts.

69. The heat needed to warm the liquid can be calculated by Eq. 19-2.

$$Q = mc\Delta T = (0.20\text{ kg})(1.00\,\text{kcal/kg}\bullet\text{C}^\circ)(37^\circ\text{C} - 5^\circ\text{C}) = 6.4\text{ kcal} = \boxed{6.4\text{ Cal}}$$

70. (*a*) Use Eq. 19-17 for total power radiated.

$$\frac{Q}{t} = e\sigma AT^4 = e\sigma 4\pi R_{\text{Sun}}^2 T^4 = (1.0)\left(5.67\times10^{-8}\,\text{W/m}^2\bullet\text{K}^4\right)4\pi\left(7.0\times10^8\,\text{m}\right)^2(5500\text{ K})^4$$

$$= 3.195\times10^{26}\,\text{W} \approx \boxed{3.2\times10^{26}\,\text{W}}$$

(*b*) Assume that the energy from the Sun is distributed symmetrically over a spherical surface with the Sun at the center.

$$\frac{P}{A} = \frac{Q/t}{4\pi R_{\text{Sun-Earth}}^2} = \frac{3.195\times10^{26}\,\text{W}}{4\pi\left(1.5\times10^{11}\,\text{m}\right)^2} = 1.130\times10^3\,\text{W/m}^2 \approx \boxed{1.1\times10^3\,\text{W/m}^2}$$

71. The heat released can be calculated by Eq. 19-2. To find the mass of the water, use the density (of pure water).

$$Q = mc\Delta T = \rho Vc\Delta T = \left(1.0\times10^3\,\text{kg/m}^3\right)\left(1.0\times10^3\,\text{m}\right)^3(4186\,\text{J/kg}\bullet\text{C}^\circ)(1\text{C}^\circ) = \boxed{4\times10^{15}\,\text{J}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

72. Use the heat conduction rate equation, Eq. 19-16a.

(*a*) $$\frac{Q}{t} = kA\frac{T_1 - T_2}{\ell} = \left(0.025\,\text{J/s•m•C°}\right)\left(0.95\,\text{m}^2\right)\frac{\left[34°\text{C} - \left(-18°\text{C}\right)\right]}{3.5\times10^{-2}\,\text{m}} = 35.3\,\text{W} \approx \boxed{35\,\text{W}}$$

(*b*) $$\frac{Q}{t} = kA\frac{T_1 - T_2}{\ell} = \left(0.56\,\text{J/s•m•C°}\right)\left(0.95\,\text{m}^2\right)\frac{\left[34°\text{C} - \left(-18°\text{C}\right)\right]}{5.0\times10^{-3}\,\text{m}} = 5533\,\text{W} \approx \boxed{5500\,\text{W}}$$

73. The temperature rise can be calculated from Eq. 19-2.

$$Q = mc\Delta T \quad \rightarrow \quad \Delta T = \frac{Q}{mc} = \frac{\left(0.80\right)\left(200\,\text{kcal/h}\right)\left(0.5\,\text{h}\right)}{\left(70\,\text{kg}\right)\left(0.83\,\text{kcal/kg•C°}\right)} = 1.38\,\text{C°} \approx \boxed{1\text{C°}}$$

74. For an estimate of the heat conduction rate, use Eq. 19-16a.

$$\frac{Q}{t} = kA\frac{T_1 - T_2}{\ell} = \left(0.2\,\text{J/s•m•C°}\right)\left(1.5\,\text{m}^2\right)\frac{\left(37°\text{C} - 34°\text{C}\right)}{4.0\times10^{-2}\,\text{m}} = 22.5\,\text{W} \approx \boxed{20\,\text{W}}$$

This is only about 10% of the cooling capacity that is needed for the body. Thus convection cooling is clearly necessary.

75. We assume that all of the heat provided by metabolism goes into evaporating the water. For the energy required for the evaporation of water, we use the heat of vaporization at room temperature (585 kcal/kg), since the runner's temperature is closer to room temperature than 100°C.

$$2.2\,\text{h}\left(\frac{950\,\text{kcal}}{1\,\text{h}}\right)\left(\frac{\text{kg}\,\text{H}_2\text{O}}{585\,\text{kcal}}\right) = \boxed{3.6\,\text{kg}}$$

76. (*a*) To calculate heat transfer by conduction, use Eq. 19-16a for all three areas – walls, roof, and windows. Each area has the same temperature difference.

$$\frac{Q_{\text{conduction}}}{t} = \left[\left(\frac{kA}{\ell}\right)_{\text{walls}} + \left(\frac{kA}{\ell}\right)_{\text{roof}} + \left(\frac{kA}{\ell}\right)_{\text{windows}}\right]\left(T_1 - T_2\right)$$

$$= \left[\begin{array}{l}\dfrac{\left(0.023\,\text{J/s•m•C°}\right)\left(410\,\text{m}^2\right)}{0.195\,\text{m}} + \dfrac{\left(0.1\,\text{J/s•m•C°}\right)\left(280\,\text{m}^2\right)}{0.055\,\text{m}} \\ \quad + \dfrac{\left(0.84\,\text{J/s•m•C°}\right)\left(33\,\text{m}^2\right)}{6.5\times10^{-3}\,\text{m}}\end{array}\right]\left(38\,\text{C°}\right)$$

$$= 1.832\times10^5\,\text{W} \approx \boxed{1.8\times10^5\,\text{W}}$$

(*b*) The energy being added must both heat the air and replace the energy lost by conduction, as considered above. The heat required to raise the temperature is given by Eq. 19-2, $Q_{\substack{\text{raise}\\\text{temp}}} = m_{\text{air}}c_{\text{air}}\left(\Delta T\right)_{\text{warming}}$. The mass of the air can be found from the density of the air times its volume. The conduction heat loss is proportional to the temperature difference between the inside and outside, which varies from 27C° to 38C°. We will estimate the average temperature difference as 32.5°C and scale the answer from part (a) accordingly.

$$Q_{\text{added}} = Q_{\substack{\text{raise}\\\text{temp}}} + Q_{\text{conduction}} = \rho_{\text{air}}Vc_{\text{air}}\left(\Delta T\right)_{\text{warming}} + \left(\frac{Q_{\text{conduction}}}{t}\right)\left(1800\,\text{s}\right)$$

$$= \left(1.29\,\frac{\text{kg}}{\text{m}^3}\right)\left(750\text{m}^3\right)\left(0.24\,\frac{\text{kcal}}{\text{kg•C°}}\right)\left(\frac{4186\,\text{J}}{\text{kcal}}\right)\left(11°\text{C}\right)$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$+\left(1.832\times10^5\,\frac{\text{J}}{\text{s}}\right)\left(\frac{32.5^\circ\text{C}}{38^\circ\text{C}}\right)(1800\,\text{s}) = \boxed{2.5\times10^8\,\text{J}}$$

(*c*) We assume a month is 30 days.

$$0.9Q_{\text{gas}} = \left(\frac{Q}{t}\right)_{\text{conduction}} t_{\text{month}} \;\rightarrow$$

$$Q_{\text{gas}} = \frac{1}{0.9}\left(\frac{Q}{t}\right)_{\text{conduction}} t_{\text{month}} = \frac{1}{0.9}\left(1.832\times10^5\,\text{J/s}\right)(30\,\text{d})\left(\frac{24\,\text{h}}{1\,\text{d}}\right)\left(\frac{3600\,\text{s}}{1\,\text{h}}\right) = 5.276\times10^{11}\,\text{J}$$

$$5.276\times10^{11}\,\text{J}\left(\frac{1\,\text{kg}}{5.4\times10^7\,\text{J}}\right)\left(\frac{\$0.080}{\text{kg}}\right) = \$781.65 \approx \boxed{\$780}$$

77. Assume that the loss of kinetic energy is all turned into heat which changes the temperature of the squash ball.

$$KE_{\text{lost}} = Q \;\rightarrow\; \tfrac{1}{2}m\left(v_i^2 - v_f^2\right) = mc\Delta T \;\rightarrow\; \Delta T = \frac{v_i^2 - v_f^2}{2c} = \frac{(22\,\text{m/s})^2 - (12\,\text{m/s})^2}{2(1200\,\text{J/kg•C°})} = \boxed{0.14\,\text{C°}}$$

78. Since the handle is pushed in very quickly, we approximate the process as adiabatic, since there will be little time for heat transfer to or from the air in the pump. We combine the ideal gas law and Eq. 19-15 for adiabatic processes.

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \;\rightarrow\; \frac{T_2}{T_1} = \frac{P_2}{P_1}\frac{V_2}{V_1} \;;\; P_1V_1^\gamma = P_2V_2^\gamma \;\rightarrow\; \frac{P_2}{P_1} = \frac{V_1^\gamma}{V_2^\gamma}$$

$$\gamma = \frac{C_P}{C_V} = \frac{C_V + R}{C_V} = \frac{\frac{5}{2}R + R}{\frac{5}{2}R} = \frac{7}{5}$$

$$\frac{T_2}{T_1} = \frac{P_2}{P_1}\frac{V_2}{V_1} = \frac{V_1^\gamma}{V_2^\gamma}\frac{V_2}{V_1} = \left(\frac{V_1}{V_2}\right)^{\gamma-1} \;\rightarrow\; T_2 = T_1\left(\frac{V_1}{V_2}\right)^{\gamma-1} = (293\,\text{K})\left(2^{0.4}\right) = 386.6\,\text{K} = \boxed{114^\circ\text{C}}$$

79. (*a*) The energy required to raise the temperature of the water is given by Eq. 19-2.

$$Q = mc\Delta T \;\rightarrow$$

$$\frac{Q}{\Delta t} = mc\frac{\Delta T}{\Delta t} = (0.250\,\text{kg})\left(4186\,\frac{\text{J}}{\text{kg•C°}}\right)\left(\frac{80\,\text{C°}}{105\,\text{s}}\right) = 797\,\text{W} \approx \boxed{800\,\text{W}\,(2\text{ sig. fig.})}$$

(*b*) After 105 s, the water is at 100°C. So for the remaining 15 s the energy input will boil the water. Use the heat of vaporization.

$$Q = mL_{\text{V}} \;\rightarrow\; m = \frac{Q}{L_{\text{V}}} = \frac{(\text{Power})\,\Delta t}{L_{\text{V}}} = \frac{(797\,\text{W})(15\,\text{s})}{2260\,\text{J/g}} = \boxed{5.3\,\text{g}}$$

80. (*a*) We consider just the 30 m of crust immediately below the surface of the Earth, assuming that all the heat from the interior gets transferred to the surface, and so it all passes through this 30 m layer. This is a heat conduction problem, and so Eq. 19-16a is appropriate. The radius of the Earth is about $6.38\times10^6\,\text{m}$.

$$\frac{Q}{t} = kA\frac{T_1 - T_2}{l} \;\rightarrow\; Q_{\text{interior}} = kA\frac{T_1 - T_2}{l}t = (0.80\,\text{J/s•m•C°})\,4\pi R_{\text{Earth}}^2\,\frac{1.0\,\text{C°}}{30\,\text{m}}\left[1\,\text{hour}\left(\frac{3600\,\text{s}}{\text{hour}}\right)\right]$$

$$= 4.910\times10^{16}\,\text{J} \approx \boxed{4.9\times10^{16}\,\text{J}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The cross-sectional area of the Earth, perpendicular to the Sun, is a circle of radius R_{Earth}, and so has an area of πR_{Earth}^2. Multiply this area times the solar constant of $1350\,\text{W}/\text{m}^2$ to get the amount of energy incident on the Earth from the Sun per second, and then convert to energy per day.

$$Q_{\text{Sun}} = \pi R_{\text{Earth}}^2 \left(1350\,\text{W}/\text{m}^2\right)\left[1\,\text{hour}\left(\frac{3600\,\text{s}}{\text{day}}\right)\right]$$

$$\frac{Q_{\text{Sun}}}{Q_{\text{interior}}} = \frac{\pi R_{\text{Earth}}^2 \left(1350\,\text{W}/\text{m}^2\right)\left[1\,\text{hour}\left(\frac{3600\,\text{s}}{\text{day}}\right)\right]}{\left(0.80\,\text{J}/\text{s}\bullet\text{m}\bullet\text{C}^\circ\right)4\pi R_{\text{Earth}}^2 \frac{1.0\,\text{C}^\circ}{30\text{ m}}\left[1\,\text{hour}\left(\frac{3600\,\text{s}}{\text{hour}}\right)\right]} = \frac{\left(1350\,\text{W}/\text{m}^2\right)}{\left(0.80\,\text{J}/\text{s}\bullet\text{m}\bullet\text{C}^\circ\right)4\frac{1.0\,\text{C}^\circ}{30\text{ m}}}$$

$$= 1.3\times 10^4$$

And so $\boxed{Q_{\text{Sun}} = 1.3\times 10^4 Q_{\text{interior}}}$.

81. Consider a rectangular block of ice. The surface area of the top of the block is A, and this surface is exposed to the air. The surface area of the bottom of the block is A, and this surface is exposed to the water. The thickness of this block is *x*. The heat of fusion from the ice forming at the bottom surface must be conducted through the ice to the air. For the conduction, from Eq. 19-16a, we have $\frac{dQ}{dt} = \frac{k_{\text{ice}} A\left(T_{\text{bottom}} - T_{\text{top}}\right)}{x}$. This is the rate of heat energy leaving the bottom surface and escaping to the air, through the ice block. For the freezing process, if a layer of ice of thickness *dx*, with mass *dm*, is formed at the bottom surface, the energy released is $dQ = L_{\text{f}}\,dm = L_{\text{f}}\rho_{\text{ice}} A\,dx$. The rate of release of this energy is $\frac{dQ}{dt} = L_{\text{f}}\rho_{\text{ice}} A\frac{dx}{dt}$. The rate of energy release must be equal to the rate of energy conduction, if the temperature at the bottom surface is to remain constant.

$$\frac{dQ}{dt} = \frac{k_{\text{ice}} A\left(T_{\text{bottom}} - T_{\text{top}}\right)}{x} = L_{\text{f}}\rho_{\text{ice}} A\frac{dx}{dt} \quad\rightarrow\quad \frac{k_{\text{ice}}\left(T_{\text{bottom}} - T_{\text{top}}\right)}{L_{\text{f}}\rho_{\text{ice}}}dt = x\,dx \quad\rightarrow$$

$$\int_0^{t_{15}} \frac{k_{\text{ice}}\left(T_{\text{bottom}} - T_{\text{top}}\right)}{L_{\text{f}}\rho_{\text{ice}}}dt = \int_0^{0.15\text{m}} x\,dx \quad\rightarrow\quad \frac{k_{\text{ice}}\left(T_{\text{bottom}} - T_{\text{top}}\right)}{L_{\text{f}}\rho_{\text{ice}}}t_{15} = \tfrac{1}{2}\left(0.15\,\text{m}\right)^2 \quad\rightarrow$$

$$t_{15} = \frac{\frac{1}{2}\left(0.15\,\text{m}\right)^2 L_{\text{f}}\rho_{\text{ice}}}{k_{\text{ice}}\left(T_{\text{bottom}} - T_{\text{top}}\right)} = \frac{\frac{1}{2}\left(0.15\,\text{m}\right)^2\left(3.33\times 10^5\,\text{J}/\text{kg}\right)\left(917\,\text{kg}/\text{m}^3\right)}{\left(2\frac{\text{J}}{\text{s}\bullet\text{m}\bullet\text{C}^\circ}\right)\left(18\,\text{C}^\circ\right)} = \boxed{9.5\times 10^4\,\text{s} \approx 1.1\,\text{d}}$$

82. Assume that the final speed of the meteorite, as it completely melts, is 0, and that all of its initial kinetic energy was used in heating the iron to the melting point and then melting the iron.

$$\tfrac{1}{2}mv_i^2 = mc_{\text{Fe}}\left(T_{\text{melt}} - T_i\right) + mL_{\text{fusion}} \quad\rightarrow$$

$$v_i = \sqrt{2\left[c_{\text{Fe}}\left(T_{\text{melt}} - T_i\right) + L_{\text{fusion}}\right]} = \sqrt{2\left[\left(450\,\text{J}/\text{kg}\bullet\text{C}^\circ\right)\left(1808^\circ\text{C} - \left(-105^\circ\text{C}\right)\right) + 2.89\times 10^5\,\text{J}/\text{kg}\right]}$$

$$= \boxed{1520\,\text{m}/\text{s}}$$

83. (*a*) The pressure varies with depth according to Eq. 13-6b. Use Eq. 13-6b to find the pressure at the original depth, and then use the ideal gas equation with a constant temperature to find the size of the bubble at the surface.

$$P_1 = P_{\text{atm}} + \rho gh \;;\; P_2 = P_{\text{atm}} \;;\; P_1V_1 = P_2V_2 \;\rightarrow\; \left(P_{\text{atm}} + \rho gh\right)\tfrac{4}{3}\pi\left(\tfrac{1}{2}d_1\right)^3 = P_{\text{atm}}\tfrac{4}{3}\pi\left(\tfrac{1}{2}d_2\right)^3 \;\rightarrow$$

$$d_2 = d_1\left(\frac{P_{\text{atm}} + \rho gh}{P_{\text{atm}}}\right)^{1/3} = d_1\left(1 + \frac{\rho gh}{P_{\text{atm}}}\right)^{1/3}$$

$$= (3.60\,\text{cm})\left[1 + \frac{\left(1000\,\text{kg/m}^3\right)\left(9.80\,\text{m/s}^2\right)(14.0\,\text{m})}{1.013\times10^5\,\text{Pa}}\right]^{1/3} = \boxed{4.79\,\text{cm}}$$

(*b*) See the accompanying graph. The path is an isotherm, so the product *PV* is constant. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH19.XLS," on tab "Problem 19.83b."

(*c*) Since the process is isothermal, Eq. 19-8 is used to calculate the work.

$$W = nRT\ln\frac{V_2}{V_1} = P_2V_2\ln\frac{V_2}{V_1}$$

$$= P_2\left[\tfrac{4}{3}\pi\left(\tfrac{1}{2}d_2\right)^3\right]\ln\frac{\tfrac{4}{3}\pi\left(\tfrac{1}{2}d_2\right)^3}{\tfrac{4}{3}\pi\left(\tfrac{1}{2}d_1\right)^3}$$

$$= P_2\left[\tfrac{1}{2}\pi d_2^3\right]\ln\left(\frac{d_2}{d_1}\right) = \left(1.013\times10^5\,\text{Pa}\right)\left[\tfrac{1}{2}\pi\left(0.0479\,\text{m}\right)^3\right]\ln\left(\frac{0.0479\,\text{m}}{0.0360\,\text{m}}\right) = \boxed{4.99\,\text{J}}$$

Since the process is isothermal, $\boxed{\Delta E_{\text{int}} = 0}$. Then, by the first law of thermodynamics,

$\Delta E_{\text{int}} = Q - W \;\rightarrow\; Q = \Delta E_{\text{int}} + W = \boxed{4.99\,\text{J}}$. The heat is added.

84. Use the first law of thermodynamics to find the rate of change of internal energy. Heat is being removed, so the heat term is negative. Work is being done on the gas, so the work term is also negative.

$$\Delta E_{\text{int}} = Q - W \;\rightarrow\; \frac{dE_{\text{int}}}{dt} = \frac{dQ}{dt} - \frac{dW}{dt} = -1.5\times10^3\,\text{W} - \left(7.5\times10^3\,\text{W}\right) = 6.0\times10^3\,\text{W}$$

This internal energy increase will happen during the compression stroke of a cycle. We assume that the time for compression is half of a cycle.

$$\Delta t_{\text{compression}} = \tfrac{1}{2}\left(\frac{1}{150\text{ cycles/min}}\right)\left(\frac{60\,\text{s}}{1\,\text{min}}\right) = 0.20\,\text{s}$$

Assume an ideal diatomic gas and use Eq. 19-12 in order to find the temperature change.

$$\Delta E_{\text{int}} = nC_V\Delta T \;\rightarrow\; \frac{dE_{\text{int}}}{dt} = nC_V\left(\frac{\Delta T}{\Delta t}\right)_{\text{compression}} \;\rightarrow$$

$$\Delta T_{\text{compression}} = \frac{dE_{\text{int}}}{dt}\frac{\Delta t_{\text{compression}}}{nC_V} = \left(6.0\times10^3\,\text{W}\right)\frac{0.20\,\text{s}}{(1.00\,\text{mol})\left(5.00\,\text{cal/mol•K}\right)\left(4.186\,\text{J/cal}\right)} = \boxed{57\text{C°}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

85. We assume that the light bulb emits energy by radiation, and so Eq. 19-18 applies. Use the data for the 75-W bulb to calculate the product $e\sigma A$ for the bulb, and then calculate the temperature of the 150-W bulb.

$$(Q/t)_{60\text{ W}} = e\sigma A\left(T_{60\text{ W}}^4 - T_{\text{room}}^4\right) \rightarrow$$

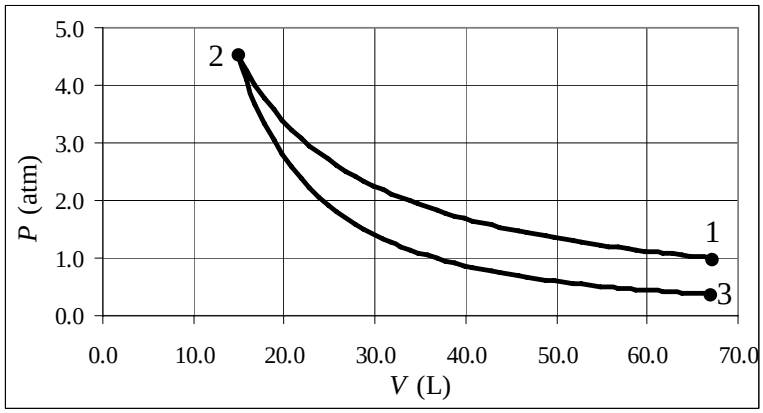
$$e\sigma A = \frac{(Q/t)_{60\text{ W}}}{\left(T_{60\text{ W}}^4 - T_{\text{room}}^4\right)} = \frac{(0.90)(75\text{ W})}{\left[(273+75)\text{ K}\right]^4 - \left[(273+18)\text{ K}\right]^4} = 9.006\times10^{-9}\text{ W/K}^4$$

$$(Q/t)_{150\text{ W}} = e\sigma A\left(T_{150\text{ W}}^4 - T_{\text{room}}^4\right) \rightarrow$$

$$T_{150\text{ W}} = \left[\frac{(Q/t)_{150\text{ W}}}{e\sigma A} + T_{\text{room}}^4\right]^{1/4} = \left[\frac{(0.90)(150\text{ W})}{\left(9.006\times10^{-9}\text{ W/K}^4\right)} + (291\text{ K})^4\right]^{1/4}$$

$$= 386\text{ K} = 113°\text{C} \approx \boxed{110°\text{C}}$$

86. Let the subscript 1 refer to the original state, subscript 2 refer to the compressed state, and subscript 3 refer to the final state. The first process is best described by the ideal gas law for constant temperature, and the second process by the adiabatic relationship in Eq. 19-15. We use the ideal gas equation to relate the initial and final temperatures. Note that the initial volume is 3 times the molar volume at STP, and so is 67.2 L.



Process 1: $P_1V_1 = P_2V_2 \rightarrow P_2 = P_1\left(\frac{V_1}{V_2}\right) = (1\text{atm})\left(\frac{1}{0.22}\right) = 4.545\text{atm}\ ;\ T_2 = T_1 = 273\text{K}$

Process 2: $P_2V_2^\gamma = P_3V_3^\gamma \rightarrow P_3 = P_2\left(\frac{V_2}{V_3}\right)^\gamma = \left(\frac{1\text{atm}}{0.22}\right)\left(\frac{0.22}{1}\right)^{5/3} = 0.3644\text{atm}$

$$\frac{P_1V_1}{T_1} = \frac{P_3V_3}{T_3} \rightarrow T_3 = T_1\left(\frac{P_3}{P_1}\right)\left(\frac{V_3}{V_1}\right) = (273\text{K})(0.3644)(1) = 99.48\text{K}$$

$$\boxed{\begin{aligned} T_{\max} &= 273\text{ K} = T_1 = T_2 \\ T_{\min} &= 99\text{ K} = T_3 \\ P_{\max} &= 4.5\text{ atm} = P_2 \\ P_{\min} &= 0.36\text{ atm} = P_3 \end{aligned}}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH19.XLS," on tab "Problem 19.86."

87. Since the specific heat is a function of temperature, we need to integrate the infinitesimal version of Eq. 19-2, and use moles instead of grams.

$dQ = nCdT \rightarrow$

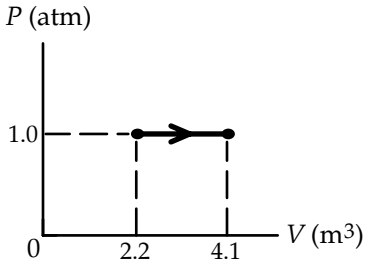
$$\Delta Q = \int_{T_1}^{T_2} nk\frac{T^3}{T_0^3}dT = \frac{nk}{4T_0^3}\left(T_2^4 - T_1^4\right) = \frac{(2.75\text{ mol})(1940\text{ J/mol•K})}{4(281\text{K})^3}\left[(48.0\text{ K})^4 - (22.0\text{ K})^4\right] = \boxed{305\text{J}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

88. Combine the ideal gas relationship for a fixed amount of gas, $\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$, with the adiabatic relationship, $P_1V_1^\gamma = P_2V_2^\gamma$.

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \rightarrow \frac{V_1}{V_2} = \frac{P_2}{P_1}\frac{T_1}{T_2} \; ; \; P_1V_1^\gamma = P_2V_2^\gamma \rightarrow \frac{P_2}{P_1} = \frac{V_1^\gamma}{V_2^\gamma}$$

$$\frac{V_1}{V_2} = \frac{V_1^\gamma}{V_2^\gamma}\frac{T_1}{T_2} \rightarrow \left(\frac{V_1}{V_2}\right)^{\gamma-1} = \frac{T_2}{T_1} \rightarrow \frac{V_1}{V_2} = \left(\frac{T_2}{T_1}\right)^{\frac{1}{\gamma-1}} = \left(\frac{273\,\text{K} + 560\,\text{K}}{280\,\text{K}}\right)^{5/2} = \boxed{15.3}$$



89. (*a*) Since the pressure is constant, the work is found using Eq. 19-9a.

$$W = P\Delta V = \left(1.013\times10^5\,\text{Pa}\right)\left(4.1\,\text{m}^3 - 2.2\,\text{m}^3\right) = 1.9247\times10^5\,\text{J} \approx \boxed{1.9\times10^5\,\text{J}}$$

(*b*) Use the first law of thermodynamics.

$$\Delta E_{\text{int}} = Q - W = 6.30\times10^5\,\text{J} - 1.92\times10^5\,\text{J} = 4.38\times10^5\,\text{J} \approx \boxed{4.4\times10^5\,\text{J}}$$

(*c*) See the accompanying graph.

90. The body's metabolism (blood circulation in particular) provides cooling by convection. If the metabolism has stopped, then heat loss will be by conduction and radiation, at a rate of 200 W, as given. The change in temperature is related to the body's heat loss by Eq. 19-2, $Q = mc\Delta T$.

$$\frac{Q}{t} = P = \frac{mc\Delta T}{t} \rightarrow$$

$$t = \frac{mc\Delta T}{P} = \frac{(70\text{ kg})(3470\,\text{J/kg•C°})(36.6°\text{C} - 35.6°\text{C})}{200\text{ W}} = \boxed{1200\text{ s}} = 20\text{ min}$$

91. The work is given by $W = \int_{V_1}^{V_2} P\,dV$. The pressure is found from the van der Waals expression, Eq. 18-9. The temperature is a constant. The analytic integration is done in problem 41.

$$W = nRT\ln\frac{(V_2 - bn)}{(V_1 - bn)} + an^2\left(\frac{1}{V_2} - \frac{1}{V_1}\right)$$

$$= (1.0\,\text{mol})(8.314\,\text{J/mol•K})(373\,\text{K})\ln\frac{\left[1.00\,\text{m}^3 - \left(3.0\times10^{-5}\,\text{m}^3\text{/mol}\right)(1.0\,\text{mol})\right]}{\left[0.50\,\text{m}^3 - \left(3.0\times10^{-5}\,\text{m}^3\text{/mol}\right)(1.0\,\text{mol})\right]}$$

$$+ \left(0.55\,\text{N•m}^4\text{/mol}^2\right)(1.0\,\text{mol})^2\left(\frac{1}{1.00\,\text{m}^3} - \frac{1}{0.50\,\text{m}^3}\right)$$

$$= 3101.122\ln\frac{\left[1.0 - \left(3.0\times10^{-5}\right)\right]}{\left[0.5 - \left(3.0\times10^{-5}\right)\right]} - 0.55 = 2149\,\text{J}$$

An acceptable answer from the numeric integration would need to be in the range of 2100 – 2200 J.

To do the numeric integration, we partition the volume range. For each volume value, the pressure is calculated using Eq. 18-9. The pressure is assumed constant over each segment of the volume partition, and then the work for that segment is the (constant) pressure times the small change in volume. Even with a relatively crude partition size of 0.1m^3, good agreement is found. The result from the numeric integration is 2158 J, which rounds to $\boxed{2200\text{ J}}$. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH19.XLS," on tab "Problem 19.91."

CHAPTER 20: Second Law of Thermodynamics

Responses to Questions

1. Yes, mechanical energy can be transformed completely into heat or internal energy, as when an object moving over a surface is brought to rest by friction. All of the original mechanical energy is converted into heat. No, the reverse cannot happen (second law of thermodynamics) except in very special cases (reversible adiabatic expansion of an ideal gas). For example, in an explosion, a large amount of internal energy is converted into mechanical energy, but some internal energy is lost to heat or remains as internal energy of the explosion fragments.

2. Yes, you can warm a kitchen in winter by leaving the oven door open. The oven converts electrical energy to heat and leaving the door open will allow this heat to enter the kitchen. However, you cannot cool a kitchen in the summer by leaving the refrigerator door open. The refrigerator is a heat engine which (with an input of work) takes heat from the low-temperature reservoir (inside the refrigerator) and exhausts heat to the high-temperature reservoir (the room). As shown by the second law of thermodynamics, there is no "perfect refrigerator," so more heat will be exhausted into the room than removed from the inside of the refrigerator. Thus, leaving the refrigerator door open will actually warm the kitchen.

3. No. The definition of heat engine efficiency as $e = W/Q_L$ does not account for Q_H, the energy needed to produce the work. Efficiency should relate the input energy and the output work.

4. (*a*) In an internal-combustion engine, the high-temperature reservoir is the ignited gas–air mixture in the cylinder. The low-temperature reservoir is the outside; the burned gases leave through the exhaust pipe.
   (*b*) In the steam engine, the high-temperature reservoir is the steam-water mixture in the boiler and the low-temperature reservoir is the condensed water in the condenser. In the cases of both these engines, these areas are not technically heat "reservoirs," because each one is not at a constant temperature.

5. A 10°C decrease in the low-temperature reservoir will give a greater improvement in the efficiency of a Carnot engine. By definition, T_L is less than T_H, so a 10°C change will be a larger percentage change in T_L than in T_H, yielding a greater improvement in efficiency.

6. A heat engine operates when heat is allowed to flow from a high-temperature area to a lower temperature area and some of the heat is converted into work in the process. In order to obtain useful work from the thermal energy in the oceans, the oceans would have to represent the high-temperature area. This is not practical since the oceans are not at a high temperature compared to their surroundings and so there is no low-temperature reservoir available for the heat engine.

7. The two main factors which keep real engines from Carnot efficiency are friction and heat loss to the environment.

8. The expansion value allows the fluid to move from an area of higher pressure to an area of lower pressure. When the fluid moves to the low pressure area, it expands rapidly (adiabatic expansion). Expansion requires energy, which is taken from the internal energy of the fluid, thus lowering its temperature.

9. Water freezing on the surface of a body of water when the temperature is 0°C is nearly a reversible process.

10. (*a*) Consider a gas enclosed in a cylinder with a movable (and frictionless) piston. If the gas and cylinder are kept at a constant temperature by contact with a thermal reservoir, then heat can be added very slowly allowing the gas to do work on the piston and expand. This isothermal expansion is reversible. If work is done very slowly on the gas, by pushing down on the piston, while the gas is still in contact with the thermal reservoir, then the same amount of heat will leave during the isothermal compression. Other processes which are not isothermal are possible, as long as they are gradual and temperature change occurs for all parts of the system at once.
(*b*) A stove burner could not be used to add heat to a system reversibly since the heat added by a burner would not be distributed uniformly throughout the system and because the energy needed to heat the burner would not be recoverable.

11. The isothermal process will result in a greater change in entropy. The entropy change for a reversible process is the integral of dQ/T. $Q = 0$ for an adiabatic process, so the change in entropy is also 0.

12. Three examples of naturally occurring processes in which order goes to disorder are a landslide, fallen leaves decaying, and a cup of coffee cooling as it sits on a table. The reverse processes are not observed.

13. 1 kg of liquid iron will have greater entropy, since it is less ordered than solid iron and its molecules have more thermal motion. In addition, heat must be added to solid iron to melt it; the addition of heat will increase the entropy of the iron.

14. (*a*) When the lid on a bottle of chlorine gas is removed, the gas mixes with the air in the room around the bottle so that eventually both the room and the bottle contain a mixture of air and chlorine.
(*b*) The reverse process, in which the individual chlorine atoms reorganize so that they occupy only the bottle, violates the second law of thermodynamics and does not occur naturally.
(*c*) Adding a drop of food coloring to a glass of water is another example of an irreversible process; the food coloring will eventually disperse throughout the water but will not ever gather into a drop again. Sliding a book across the floor is another example. Friction between the book and the floor will cause the kinetic energy to be dissipated as thermal energy and the book will eventually come to rest. There is no way to reverse this process and take thermal energy from the book and the floor and turn it into organized kinetic energy of the book.

15. The machine is clearly doing work to remove heat from some of the air in the room. The waste heat is dumped back into the room, and the heat generated in the process of doing work is also dumped into the room. The net result is the addition of heat into the room by the machine.

16. Some processes that would obey the first law of thermodynamics but not the second, if they actually occurred, include: a cup of tea warming itself by gaining thermal energy from the cooler air molecules around it, a ball sitting on a soccer field gathering energy from the grass and beginning to roll, and a bowl of popcorn placed in the refrigerator and unpopping as it cools.

17. No. While you have reduced the entropy of the papers, you have increased your own entropy by doing work, for which your muscles have consumed energy. The entropy of the universe has increased as a result of your actions.

18. The first law of thermodynamics is essentially a statement of the conservation of energy. “You can’t get something for nothing” is similar to the statement that “energy can be neither created nor destroyed.” If the “something” you want to get is useful work, then input energy is required. The second law concerns the direction of energy transfers. The Kelvin-Planck statement of the second

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

law says that "no device is possible whose sole effect is to transform a given amount of heat completely into work." In other words, 100 joules of heat will result is something less than 100 joules of work, so "you can't even break even."

19. No. Even if the powdered milk is added very slowly, it cannot be re-extracted from the water without very large investments of energy. This is not a reversible process.

20. Entropy is a state variable, so the change in entropy for the system will be the same for the two different irreversible processes that take the system from state a to state b. However, the change in entropy for the environment will not necessarily be the same. The total change in entropy (system plus environment) will be positive for irreversible processes, but the amount may be different for different irreversible processes.

21. For a reversible process, $\Delta S_{\text{total}} = \Delta S_{\text{system}} + \Delta S_{\text{environment}} = 0$. Neither the process, nor its reverse process, would cause an increase in entropy. A "nearly reversible" process would have only a small increase in entropy, and the reverse process would require only a small input of energy. The greater ΔS_{total}, the more energy would be needed to reverse the process.

22. For reversible processes, the change in entropy is proportional to Q. Therefore, for a reversible, *adiabatic* process $\Delta S_{\text{total}} = 0$ because $Q = 0$. For an irreversible process, ΔS_{system} can be calculated by finding a series of reversible processes (not all of which will be adiabatic) that take the system between the same two states. The change in entropy for the system will be positive, since not all of the reversible processes will be adiabatic, and the change in the entropy of the environment will be zero. The total change in entropy for the irreversible adiabatic process will be positive.

Solutions to Problems

In solving these problems, the authors did not always follow the rules of significant figures rigidly. We tended to take quoted temperatures as correct to the number of digits shown, especially where other values might indicate that.

1. The efficiency of a heat engine is given by Eq. 20-1a. We also invoke energy conservation.

$$e = \frac{W}{Q_{\text{H}}} = \frac{W}{W + Q_{\text{L}}} = \frac{2600\text{ J}}{2600\text{ J} + 7800\text{ J}} = 0.25 = \boxed{25\%}$$

2. The efficiency of a heat engine is given by Eq. 20-1a. We also invoke energy conservation.

$$e = \frac{W}{Q_{\text{H}}} = \frac{W}{W + Q_{\text{L}}} \quad \rightarrow \quad Q_{\text{L}} = W\left(1/e - 1\right) \quad \rightarrow$$

$$Q_{\text{L}}/t = W/t\left(1/e - 1\right) = \left(580\text{ MW}\right)\left(1/0.35 - 1\right) = 1.077 \times 10^3\text{ MW} \approx \boxed{1.1 \times 10^3\text{ MW}}$$

3. We calculate both the energy per second (power) delivered by the gasoline, and the energy per second (power) needed to overcome the drag forces. The ratio of these is the efficiency.

$$\frac{W}{t} = P_{\substack{\text{output} \\ \text{(to move} \\ \text{car)}}} = Fv = \left(350\text{ N}\right)\left(55\frac{\text{mi}}{\text{h}}\right)\left(\frac{1609\text{ m}}{1\text{ mi}}\right)\left(\frac{1\text{ h}}{3600\text{ s}}\right) = 8604\text{ W}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{Q_{\text{H}}}{t} = P_{\substack{\text{input}\\(\text{from}\\\text{gasoline})}} = \left(3.2\times10^{7}\,\frac{\text{J}}{\text{L}}\right)\left(\frac{3.8\,\text{L}}{1\,\text{gal}}\right)\left(\frac{1\,\text{gal}}{35\,\text{mi}}\right)\left(55\frac{\text{mi}}{\text{h}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right) = 53079\,\text{W}$$

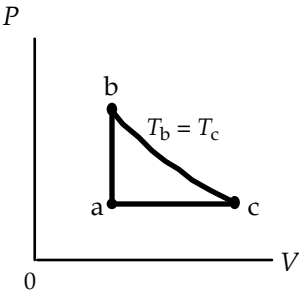
$$e = \frac{W}{Q_{\text{H}}} = \frac{P_{\substack{\text{output}\\(\text{to move}\\\text{car})}}}{P_{\substack{\text{input}\\(\text{from}\\\text{gasoline})}}} = \frac{8604\,\text{W}}{53079\,\text{W}} = \boxed{0.16}$$

4. (*a*) The work done per second is found from the engine specifications.

$$\frac{W}{t} = \left(180\frac{\text{J}}{\text{cycle•cylinder}}\right)(4\,\text{cylinders})\left(25\frac{\text{cycles}}{\text{s}}\right) = \boxed{1.8\times10^{4}\,\text{J/s}}$$

(*b*) The efficiency is given by Eq. 20-1a.

$$e = \frac{W}{Q_{\text{H}}} = \;\rightarrow\; Q_{\text{H}} = \frac{W}{e} \;\rightarrow\; Q_{\text{H}}/t = \frac{W/t}{e} = \frac{1.8\times10^{4}\,\text{J/s}}{0.22} = 8.182\times10^{4}\,\text{J/s} \approx \boxed{8.2\times10^{4}\,\text{J/s}}$$



(*c*) Divide the energy in a gallon of gasoline by the rate at which that energy gets used.

$$\frac{130\times10^{6}\,\text{J/gal}}{8.182\times10^{4}\,\text{J/s}} = 1589\,\text{s} \approx \boxed{26\,\text{min}}$$

5. The efficiency is the work done by the engine, divided by the heat input to the engine from the burning of the gasoline. Both energy terms are expressed in terms of a rate. The gasoline provides the input energy, and the horsepower of the engine represents the output work.

$$e = \frac{W}{Q_{\text{H}}} = \frac{W/t}{Q_{\text{H}}/t} = \frac{(25\,\text{hp})\left(\frac{746\,\text{W}}{1\,\text{hp}}\right)\left(\frac{1\,\text{J/s}}{1\,\text{W}}\right)}{\left(3.0\times10^{4}\,\frac{\text{kcal}}{\text{gal}}\right)\left(\frac{1\,\text{gal}}{38\,\text{km}}\right)\left(95\frac{\text{km}}{\text{h}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)\left(\frac{4186\,\text{J}}{\text{kcal}}\right)} = \boxed{0.21\text{ or }21\%}$$

6. (*a*) For the net work done by the engine to be positive, the path must be carried out clockwise. Then the work done by process bc is positive, the work done by process ca is negative, and the work done by process ab is 0. From the shape of the graph, we see that $|W_{\text{bc}}| > |W_{\text{ca}}|$.

(*b*) The efficiency of the engine is given by Eq. 20-1a. So we need to find the work done and the heat input. At first glance we might assume that we need to find the pressure, volume, and temperature at the three points on the graph. But as shown here, only the temperatures and the first law of thermodynamics are needed, along with ratios that are obtained from the ideal gas law.

ab: $W_{\text{ab}} = P\Delta V = 0$; $Q_{\text{ab}} = \Delta E_{\substack{\text{int}\\\text{ab}}} = nC_V\left(T_{\text{b}} - T_{\text{a}}\right) = \frac{3}{2}nR\left(T_{\text{b}} - T_{\text{a}}\right) > 0$

bc: $\Delta E_{\substack{\text{int}\\\text{bc}}} = nC_V\left(T_{\text{c}} - T_{\text{b}}\right) = 0$; $Q_{\text{bc}} = W_{\text{bc}} = nRT_{\text{b}}\ln\frac{V_{\text{c}}}{V_{\text{b}}} = nRT_{\text{b}}\ln\frac{V_{\text{c}}}{V_{\text{a}}} = nRT_{\text{b}}\ln\frac{T_{\text{c}}}{T_{\text{a}}} > 0$

ca: $W_{\text{ca}} = P_{\text{a}}\left(V_{\text{a}} - V_{\text{c}}\right) = \frac{nRT_{\text{a}}}{V_{\text{a}}}\left(V_{\text{a}} - V_{\text{c}}\right) = nRT_{\text{a}}\left(1 - \frac{V_{\text{c}}}{V_{\text{a}}}\right) = nRT_{\text{a}}\left(1 - \frac{T_{\text{c}}}{T_{\text{a}}}\right) = nR\left(T_{\text{a}} - T_{\text{c}}\right)$

$Q_{\text{ca}} = nC_P\left(T_{\text{a}} - T_{\text{c}}\right) = \frac{5}{2}nR\left(T_{\text{a}} - T_{\text{c}}\right) < 0$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$e=\frac{W}{Q_{\text{input}}}=\frac{W_{\text{bc}}+W_{\text{ca}}}{Q_{\text{ab}}+Q_{\text{bc}}}=\frac{nRT_{\text{b}}\ln\frac{T_{\text{c}}}{T_{\text{a}}}+nR\left(T_{\text{a}}-T_{\text{c}}\right)}{\frac{3}{2}nR\left(T_{\text{b}}-T_{\text{a}}\right)+nRT_{\text{b}}\ln\frac{T_{\text{c}}}{T_{\text{a}}}}=\frac{T_{\text{b}}\ln\frac{T_{\text{c}}}{T_{\text{a}}}+\left(T_{\text{a}}-T_{\text{c}}\right)}{\frac{3}{2}\left(T_{\text{b}}-T_{\text{a}}\right)+T_{\text{b}}\ln\frac{T_{\text{c}}}{T_{\text{a}}}}=\frac{T_{\text{b}}\ln\frac{T_{\text{b}}}{T_{\text{a}}}+\left(T_{\text{a}}-T_{\text{b}}\right)}{\frac{3}{2}\left(T_{\text{b}}-T_{\text{a}}\right)+T_{\text{b}}\ln\frac{T_{\text{b}}}{T_{\text{a}}}}$$

$$=\frac{(423\text{K})\ln\frac{423\text{K}}{273\text{K}}+(273\text{K}-423\text{K})}{\frac{3}{2}(423\text{K}-273\text{K})+(423\text{K})\ln\frac{423\text{K}}{273\text{K}}}=0.0859=\boxed{8.59\%}$$

Of course, individual values could have been found for the work and heat on each process, and used in the efficiency equation instead of referring everything to the temperatures.

7. (*a*) To find the efficiency, we need the heat input and the heat output. The heat input occurs at constant pressure, and the heat output occurs at constant volume. Start with Eq. 20-1b.

$$e=1-\frac{Q_{\text{L}}}{Q_{\text{H}}}=1-\frac{nC_{\text{V}}\left(T_{\text{d}}-T_{\text{a}}\right)}{nC_{\text{P}}\left(T_{\text{c}}-T_{\text{b}}\right)}=1-\frac{\left(T_{\text{d}}-T_{\text{a}}\right)}{\gamma\left(T_{\text{c}}-T_{\text{b}}\right)}$$

So we need to express the temperatures in terms of the corresponding volume, and use the ideal gas law and the adiabatic relationship between pressure and volume to get those expressions. Note that $P_{\text{c}}=P_{\text{b}}$ and $V_{\text{d}}=V_{\text{a}}$.

$$PV=nRT\ \rightarrow\ T=\frac{PV}{nR}\ \rightarrow$$

$$e=1-\frac{\left(\frac{P_{\text{d}}V_{\text{d}}}{nR}-\frac{P_{\text{a}}V_{\text{a}}}{nR}\right)}{\gamma\left(\frac{P_{\text{c}}V_{\text{c}}}{nR}-\frac{P_{\text{b}}V_{\text{b}}}{nR}\right)}=1-\frac{\left(P_{\text{d}}V_{\text{d}}-P_{\text{a}}V_{\text{a}}\right)}{\gamma\left(P_{\text{c}}V_{\text{c}}-P_{\text{b}}V_{\text{b}}\right)}=1-\frac{V_{\text{a}}\left(P_{\text{d}}-P_{\text{a}}\right)}{\gamma P_{\text{b}}\left(V_{\text{c}}-V_{\text{b}}\right)}=1-\frac{\left(\frac{P_{\text{d}}}{P_{\text{c}}}-\frac{P_{\text{a}}}{P_{\text{b}}}\right)}{\gamma\left(\frac{V_{\text{c}}}{V_{\text{a}}}-\frac{V_{\text{b}}}{V_{\text{a}}}\right)}$$

Use the adiabatic relationship between pressure and volume on the two adiabatic paths.

$$P_{\text{d}}V_{\text{d}}^{\gamma}=P_{\text{c}}V_{\text{c}}^{\gamma}\ \rightarrow\ \frac{P_{\text{d}}}{P_{\text{c}}}=\left(\frac{V_{\text{c}}}{V_{\text{d}}}\right)^{\gamma}=\left(\frac{V_{\text{c}}}{V_{\text{a}}}\right)^{\gamma}\ ;\ P_{\text{a}}V_{\text{a}}^{\gamma}=P_{\text{b}}V_{\text{b}}^{\gamma}\ \rightarrow\ \frac{P_{\text{a}}}{P_{\text{b}}}=\left(\frac{V_{\text{b}}}{V_{\text{a}}}\right)^{\gamma}$$

$$e=1-\frac{\left(\frac{P_{\text{d}}}{P_{\text{c}}}-\frac{P_{\text{a}}}{P_{\text{b}}}\right)}{\gamma\left(\frac{V_{\text{c}}}{V_{\text{a}}}-\frac{V_{\text{b}}}{V_{\text{a}}}\right)}=1-\frac{\left(\frac{V_{\text{c}}}{V_{\text{a}}}\right)^{\gamma}-\left(\frac{V_{\text{b}}}{V_{\text{a}}}\right)^{\gamma}}{\gamma\left[\left(\frac{V_{\text{a}}}{V_{\text{c}}}\right)^{-1}-\left(\frac{V_{\text{a}}}{V_{\text{b}}}\right)^{-1}\right]}=\boxed{1-\frac{\left(\frac{V_{\text{a}}}{V_{\text{c}}}\right)^{-\gamma}-\left(\frac{V_{\text{a}}}{V_{\text{b}}}\right)^{-\gamma}}{\gamma\left[\left(\frac{V_{\text{a}}}{V_{\text{c}}}\right)^{-1}-\left(\frac{V_{\text{a}}}{V_{\text{b}}}\right)^{-1}\right]}}$$

(*b*) For a diatomic ideal gas, $\gamma=\frac{7}{5}=1.4$.

$$e=1-\frac{\left(\frac{V_{\text{a}}}{V_{\text{c}}}\right)^{-\gamma}-\left(\frac{V_{\text{a}}}{V_{\text{b}}}\right)^{-\gamma}}{\gamma\left[\left(\frac{V_{\text{a}}}{V_{\text{c}}}\right)^{-1}-\left(\frac{V_{\text{a}}}{V_{\text{b}}}\right)^{-1}\right]}=1-\frac{(4.5)^{-1.4}-(16)^{-1.4}}{1.4\left[(4.5)^{-1}-(16)^{-1}\right]}=\boxed{0.55}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

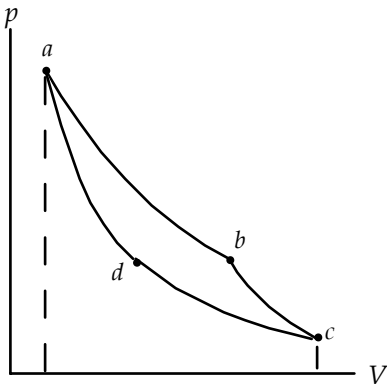
8. The maximum efficiency is the Carnot efficiency, given in Eq. 20-3.

$$e = 1 - \frac{T_L}{T_H} = 1 - \frac{(365+273)\,\text{K}}{(550+273)\,\text{K}} = \boxed{0.225 \text{ or } 22.5\%}$$

We assume that both temperatures are measured to the same precision – the nearest degree.

9. Calculate the Carnot efficiency for the given temperatures.

$$e_{\text{ideal}} = 1 - \frac{T_L}{T_H} = 1 - \frac{77\ \text{K}}{293\ \text{K}} = 0.7372 \approx \boxed{74\%}$$



10. Find the intake temperature from the original Carnot efficiency, and then recalculate the exhaust temperature for the new Carnot efficiency, using the same intake temperature.

$$e_1 = 1 - \frac{T_{L1}}{T_H} \quad \rightarrow \quad T_H = \frac{T_{L1}}{1-e_1} = \frac{(340+273)\,\text{K}}{1-0.38} = 989\ \text{K}$$

$$e_2 = 1 - \frac{T_{L2}}{T_H} \quad \rightarrow \quad T_{L2} = T_H(1-e_2) = (989\,\text{K})(1-0.45) = 544\,\text{K} = 271°\text{C} \approx \boxed{270°\text{C}}$$

11. (*a*) The work done during any process is given by Eq. 19-7. So the net work done is as follows.

$$\begin{aligned} W &= W_{ab} + W_{bc} + W_{cd} + W_{da} \\ &= \int_a^b P\,dV + \int_b^c P\,dV + \int_c^d P\,dV + \int_d^a P\,dV \\ &= \left(\int_a^b P\,dV + \int_b^c P\,dV\right) - \left(\int_a^d P\,dV + \int_d^c P\,dV\right) \end{aligned}$$

The sum of the first two terms is the area under the abc path (the "upper" path), and the sum of the last two terms is the area under the adc path (the "lower" path). So the net work is the area enclosed by the cycle.

(*b*) Any reversible cycle can be represented as a closed loop in the *P*-*V* plane. If we select the two points on the loop with the maximum and minimum volumes, we can apply the reasoning from above to find the net work.

12. This is a perfect Carnot engine, and so its efficiency is given by Eq. 20-1a and Eq. 20-3. Use these two expressions to solve for the rate of heat output.

$$e = 1 - \frac{T_L}{T_H} = 1 - \frac{(45+273)\,\text{K}}{(210+273)\,\text{K}} = 0.3416 \qquad e = \frac{W}{Q_H} = \frac{W}{W+Q_L} \quad \rightarrow \quad Q_L = W(1/e - 1)$$

$$Q_L/t = W/t(1/e-1) = (950\ \text{W})(1/0.3416 - 1) = 1831\,\text{W} \approx \boxed{1800\,\text{W}}$$

13. The maximum (or Carnot) efficiency is given by Eq. 20-3, with temperatures in Kelvins.

$$e = 1 - \frac{T_L}{T_H} = 1 - \frac{(330+273)\,\text{K}}{(665+273)\,\text{K}} = 0.354$$

Thus the total power generated can be found as follows.

$$\text{Actual Power} = (\text{Total Power})(\text{max. eff.})(\text{operating eff.}) \quad \rightarrow$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\text{Total Power} = \frac{\text{Actual Power}}{(\text{max. eff.})(\text{operating eff.})} = \frac{1.2\,\text{GW}}{(0.354)(0.65)} = 5.215\,\text{GW}$$

$$\text{Exhaust Power} = \text{Total Power} - \text{Actual Power} = 5.215\ \text{GW} - 1.2\ \text{GW} = 4.015\ \text{GW}$$

$$= \left(4.015\times10^{9}\ \text{J/s}\right)\left(3600\,\text{s/h}\right) = \boxed{1.4\times10^{13}\ \text{J/h}}$$

14. This is a perfect Carnot engine, and so its efficiency is given by Eq. 20-1a and Eq. 20-3. Equate these two expressions for the efficiency.

$$e = 1 - \frac{T_\text{L}}{T_\text{H}} = \frac{W}{Q_\text{H}} \quad \rightarrow$$

$$T_\text{L} = T_\text{H}\left(1 - \frac{W}{Q_\text{H}}\right) = T_\text{H}\left(1 - \frac{W/t}{Q_\text{H}/t}\right) = \left[(560 + 273)\,\text{K}\right]\left(1 - \frac{5.2\times10^{5}\ \text{J/s}}{(950\,\text{kcal/s})(4186\,\text{J/kcal})}\right)$$

$$= 724\ \text{K} = 451°\text{C} \approx \boxed{450°\text{C}}$$

15. We assume the efficiency of the person's metabolism is that of a reversible engine. Then we take the work from that "engine" and assume that it is all used to increase the person's potential energy by climbing higher.

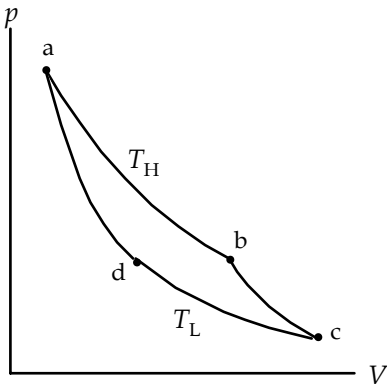
$$e = 1 - \frac{T_\text{L}}{T_\text{H}} = \frac{W}{Q_\text{H}} = \frac{mgh}{Q_\text{H}} \quad \rightarrow$$

$$h = \frac{Q_\text{H}}{mg}\left(1 - \frac{T_\text{L}}{T_\text{H}}\right) = \frac{4.0\times10^{3}\,\text{kcal}\left(\frac{4186\,\text{J}}{1\,\text{kcal}}\right)}{(65\,\text{kg})\left(9.80\,\text{m/s}^2\right)}\left(1 - \frac{(273+20)\,\text{K}}{(273+37)\,\text{K}}\right) = 1441\,\text{m} \approx \boxed{1400\,\text{m}}$$

16. The minimum value for T_H would occur if the engine were a Carnot engine. We calculate the efficiency of the engine from the given data, and use this as a Carnot efficiency to calculate T_H.

$$\frac{W}{t} = P_{\substack{\text{output}\\(\text{to move}\\ \text{car})}} = 7000\,\text{W}\ ;\ \frac{Q_\text{H}}{t} = P_{\substack{\text{input}\\(\text{from}\\ \text{gasoline})}} = \left(3.2\times10^{7}\,\frac{\text{J}}{\text{L}}\right)\left(\frac{1\,\text{L}}{17000\,\text{m}}\right)\left(\frac{20\,\text{m}}{1\,\text{s}}\right) = 37647\,\text{W}$$

$$e = \frac{W}{Q_\text{H}} = \frac{P_{\substack{\text{output}\\(\text{to move}\\ \text{car})}}}{P_{\substack{\text{input}\\(\text{from}\\ \text{gasoline})}}} = \frac{7000\,\text{W}}{37647\,\text{W}} = 1 - \frac{T_\text{L}}{T_\text{H}} \quad \rightarrow \quad T_\text{H} = \frac{T_\text{L}}{(1-e)} = \frac{(273+25)\,\text{K}}{\left(1 - \frac{7000\,\text{W}}{37647\,\text{W}}\right)} = 366\,\text{K} = \boxed{93°\text{C}}$$



17. Find the exhaust temperature from the original Carnot efficiency, and then recalculate the intake temperature for the new Carnot efficiency, using the same exhaust temperature.

$$e_1 = 1 - \frac{T_\text{L}}{T_\text{H1}} \quad \rightarrow \quad T_\text{L} = T_\text{H1}(1-e) = (580\,\text{K} + 273\,\text{K})(1 - 0.32) = 580.0\,\text{K}$$

$$e_2 = 1 - \frac{T_\text{L}}{T_\text{H2}} \quad \rightarrow \quad T_\text{H2} = \frac{T_\text{L}}{1-e_2} = \frac{580.0\ \text{K}}{1 - 0.38} = 936\ \text{K} = 663^\text{o}\text{C} \approx \boxed{660^\text{o}\text{C}}$$

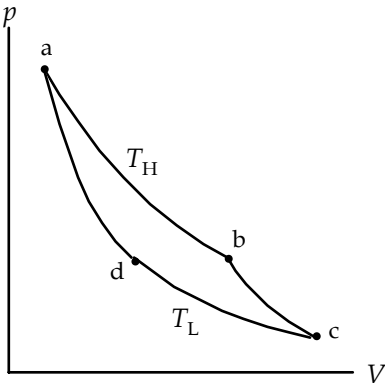
18. The heat input must come during the isothermal expansion. From section 20-3, page 534, we have $Q_H = nRT_H \ln\dfrac{V_b}{V_a} = nRT_H \ln 2$.

Since this is a Carnot cycle, we may use Eq. 20-3 combined with Eq. 20-1.

$$e = 1 - \frac{T_L}{T_H} = \frac{W}{Q_H} \rightarrow$$

$$W = Q_H\left(\frac{T_H - T_L}{T_H}\right) = \left(nRT_H \ln 2\right)\left(\frac{T_H - T_L}{T_H}\right) = nR\left(T_H - T_L\right)\ln 2$$

The adiabatic relationship between points b and c and the ideal gas law are used to express the temperature ratio in terms of the volume ratio.



$$P_bV_b^\gamma = P_cV_c^\gamma \rightarrow \frac{nRT_H}{V_b}V_b^\gamma = \frac{nRT_L}{V_c}V_c^\gamma \rightarrow T_H = T_L\left(\frac{V_c}{V_b}\right)^{\gamma-1} = T_L\left(5.7^{2/3}\right)$$

$$W = nR\left(T_H - T_L\right)\ln 2 = nRT_L\left(5.7^{2/3} - 1\right)\ln 2 \rightarrow$$

$$T_L = \frac{W}{nR\ln 2\left[5.7^{2/3} - 1\right]} = \frac{920\,\text{J}}{(1.00\,\text{mol})(8.314\,\text{J/mol•K})\ln 2\left[5.7^{2/3} - 1\right]} = 72.87\,\text{K} \approx \boxed{73\,\text{K}}$$

$$T_H = (72.87\,\text{K})\left(5.7^{2/3}\right) = 232.52\,\text{K} \approx \boxed{233\,\text{K}}$$

19. (*a*) The pressures can be found from the ideal gas equation.

$$PV = nRT \rightarrow P = \frac{nRT}{V} \rightarrow$$

$$P_a = \frac{nRT_a}{V_a} = \frac{(0.50\,\text{mol})(8.314\,\text{J/mol•K})(743\,\text{K})}{7.5\times10^{-3}\,\text{m}^3}$$

$$= 4.118\times10^5\,\text{Pa} \approx \boxed{4.1\times10^5\,\text{Pa}}$$

$$P_b = \frac{nRT_b}{V_b} = \frac{(0.50\,\text{mol})(8.314\,\text{J/mol•K})(743\,\text{K})}{15.0\times10^{-3}\,\text{m}^3}$$

$$= 2.059\times10^5\,\text{Pa} \approx \boxed{2.1\times10^5\,\text{Pa}}$$

(*b*) The volumes can be found from combining the ideal gas law and the relationship between pressure and volume for an adiabatic process.

$$P_cV_c^\gamma = P_bV_b^\gamma \rightarrow \frac{nRT_c}{V_c}V_c^\gamma = \frac{nRT_b}{V_b}V_b^\gamma \rightarrow T_cV_c^{\gamma-1} = T_bV_b^{\gamma-1} \rightarrow$$

$$V_c = \left(\frac{T_b}{T_c}\right)^{\frac{1}{\gamma-1}}V_b = \left(\frac{743\,\text{K}}{533\,\text{K}}\right)^{2.5}(15.0\,\text{L}) = \boxed{34.4\,\text{L}}$$

$$V_d = \left(\frac{T_a}{T_d}\right)^{\frac{1}{\gamma-1}}V_a = \left(\frac{743\,\text{K}}{533\,\text{K}}\right)^{2.5}(7.5\,\text{L}) = 17.2\,\text{L} \approx \boxed{17\,\text{L}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

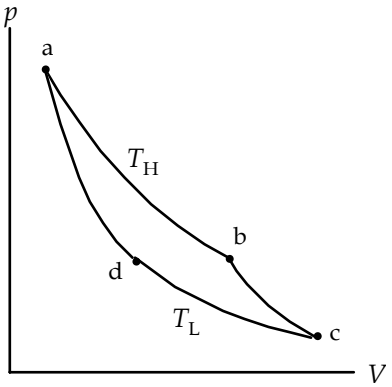
(*c*) The work done at a constant temperature is given by Eq. 19-8.

$$W = nRT\ln\left(\frac{V_b}{V_a}\right) = (0.50\,\text{mol})(8.314\,\text{J/mol•K})(743\,\text{K})\ln\left(\frac{15.0}{7.5}\right) = 2141\,\text{J} \approx \boxed{2100\,\text{J}}$$

Note that this is also the heat input during that process.

(*d*) Along process cd, there is no change in internal energy since the process is isothermic. Thus by the first law of thermodynamics, the heat exhausted is equal to the work done during that process.

$$Q = W = nRT\ln\left(\frac{V_d}{V_c}\right) = (0.50\,\text{mol})(8.314\,\text{J/mol•K})(533\,\text{K})\ln\left(\frac{17.2}{34.4}\right) = -1536\,\text{J} \approx \boxed{-1500\,\text{J}}$$



So 2100 J of heat was exhausted during process cd.

(*e*) From the first law of thermodynamics, for a closed cycle, the net work done is equal to the net heat input.

$$W_{\text{net}} = Q_{\text{net}} = 2141\,\text{J} - 1536\,\text{J} = 605\,\text{J} \approx \boxed{600\,\text{J}}$$

(*f*) $e = \dfrac{W}{Q_H} = \dfrac{605\,\text{J}}{2141\,\text{J}} = \boxed{0.28}$; $e = 1 - \dfrac{T_L}{T_H} = 1 - \dfrac{533\,\text{K}}{743\,\text{K}} = 0.28$

20. (*a*) We use the ideal gas law and the adiabatic process relationship to find the values of the pressure and volume at each of the four points.

$$P_a = \boxed{8.8\,\text{atm}}\ ;\ T_a = 623\,\text{K}\ ;$$

$$V_a = \frac{nRT_a}{P_a} = \frac{(1.00\,\text{mol})(0.0821\,\text{L•atm/mol•K})(623\,\text{K})}{8.8\,\text{atm}}$$

$$= 5.81\,\text{L} \approx \boxed{5.8\,\text{L}}$$

$$T_b = 623\,\text{K}\ ;\ V_b = 2V_a = 2(5.81\,\text{L}) = 11.62\,\text{L} \approx \boxed{11.6\,\text{L}}$$

$$P_b = P_a\frac{V_a}{V_b} = \tfrac{1}{2}P_a = \boxed{4.4\,\text{atm}}$$

$$T_c = 483\,\text{K}\ ;\ P_bV_b^\gamma = P_cV_c^\gamma \ \rightarrow\ \frac{nRT_b}{V_b}V_b^\gamma = \frac{nRT_c}{V_c}V_c^\gamma \ \rightarrow$$

$$V_c = V_b\left(\frac{T_b}{T_c}\right)^{\frac{1}{\gamma-1}} = (11.62\,\text{L})\left(\frac{623\,\text{K}}{483\,\text{K}}\right)^{3/2} = 17.02\,\text{L} \approx \boxed{17.0\,\text{L}}$$

$$P_c = \frac{nRT_c}{V_c} = \frac{(1.00\,\text{mol})(0.0821\,\text{L•atm/mol•K})(483\,\text{K})}{17.02\,\text{L}} = 2.33\,\text{atm} \approx \boxed{2.3\,\text{atm}}$$

$$T_d = 483\,\text{K}\ ;\ V_d = V_a\left(\frac{T_a}{T_d}\right)^{\frac{1}{\gamma-1}} = (5.81\,\text{L})\left(\frac{623\,\text{K}}{483\,\text{K}}\right)^{3/2} = 8.51\,\text{L} \approx \boxed{8.5\,\text{L}}$$

$$P_d = \frac{nRT_d}{V_d} = \frac{(1.00\,\text{mol})(0.0821\,\text{L•atm/mol•K})(483\,\text{K})}{8.51\,\text{L}} = 4.66\,\text{atm} \approx \boxed{4.7\,\text{atm}}$$

To summarize:

$$P_a = \boxed{8.8\,\text{atm}}\ ;\ V_a = \boxed{5.8\,\text{L}}\ ;\ P_b = \boxed{4.4\,\text{atm}}\ ;\ V_b = \boxed{11.6\,\text{L}}$$
$$P_c = \boxed{2.3\,\text{atm}}\ ;\ V_c = \boxed{17.0\,\text{L}}\ ;\ P_d = \boxed{4.7\,\text{atm}}\ ;\ V_d = \boxed{8.5\,\text{L}}$$

(*b*) Isotherm ab: $\Delta E_{\text{int}}{}_{\text{ab}} = \boxed{0}$;

$$Q_{\text{ab}} = W_{\text{ab}} = nRT_a \ln\frac{V_{\text{b}}}{V_{\text{a}}} = (1.00\,\text{mol})(8.314\,\text{J/mol•K})(623\,\text{K})\ln 2 = 3590\,\text{J} \approx \boxed{3600\,\text{J}}$$

Adiabat bc: $Q_{\text{bc}} = \boxed{0}$;

$$\Delta E_{\text{int}}{}_{\text{bc}} = nC_V(T_{\text{c}} - T_{\text{b}}) = \tfrac{3}{2}nR(T_{\text{c}} - T_{\text{b}}) = \tfrac{3}{2}(1.00\,\text{mol})(8.314\,\text{J/mol•K})(-140\,\text{K})$$

$$= -1746\,\text{J} \approx \boxed{-1700\,\text{J}} \;\; ; \;\; W_{\text{bc}} = Q_{\text{bc}} - \Delta E_{\text{int}}{}_{\text{bc}} = 1746\,\text{J} \approx \boxed{1700\,\text{J}}$$

Isotherm cd: $\Delta E_{\text{int}}{}_{\text{cd}} = \boxed{0}$;

$$Q_{\text{cd}} = W_{\text{cd}} = nRT_c \ln\frac{V_{\text{d}}}{V_{\text{c}}} = (1.00\,\text{mol})(8.314\,\text{J/mol•K})(483\,\text{K})\ln\tfrac{1}{2} = -2783\,\text{J} \approx \boxed{-2800\,\text{J}}$$

Adiabat da: $Q_{\text{da}} = \boxed{0}$;

$$\Delta E_{\text{int}}{}_{\text{bc}} = nC_V(T_{\text{c}} - T_{\text{b}}) = \tfrac{3}{2}nR(T_{\text{c}} - T_{\text{b}}) = \tfrac{3}{2}(1.00\,\text{mol})(8.314\,\text{J/mol•K})(140\,\text{K})$$

$$= 1746\,\text{J} \approx \boxed{1700\,\text{J}} \;\; ; \;\; W_{\text{bc}} = Q_{\text{bc}} - \Delta E_{\text{int}}{}_{\text{bc}} = 1746\,\text{J} \approx \boxed{-1700\,\text{J}}$$

To summarize:

ab: $\Delta E_{\text{int}} = 0$; $Q = 3600\,\text{J}$; $W = 3600\,\text{J}$

bc: $\Delta E_{\text{int}} = -1700\,\text{J}$; $Q = 0$; $W = 1700\,\text{J}$

cd: $\Delta E_{\text{int}} = 0$; $Q = -2800\,\text{J}$; $W = -2800\,\text{J}$

da: $\Delta E_{\text{int}} = 1700\,\text{J}$; $Q = 0$; $W = -1700\,\text{J}$

(*c*) Using Eq. 20-1: $$e = \frac{W}{Q_{\text{input}}} = \frac{3590\,\text{J} + 1746\,\text{J} - 2783\,\text{J} - 1746\,\text{J}}{3590\,\text{J}} = \frac{807\,\text{J}}{3590\,\text{J}} = 0.2248 \approx \boxed{0.22}$$

Using Eq. 20-3: $$e = 1 - \frac{T_{\text{L}}}{T_{\text{H}}} = 1 - \frac{(273 + 210)\,\text{K}}{(273 + 350)\,\text{K}} = 0.2247 \approx \boxed{0.22}$$

The slight disagreement is due to rounding of various calculations.

21. The adiabatic compression takes place between temperatures of 25°C and 430°C. Use the adiabatic relationship and the ideal gas law to express the volumes in terms of the temperatures.

$$P_{\text{a}}V_{\text{a}}^{\gamma} = P_{\text{b}}V_{\text{b}}^{\gamma} \;\; ; \;\; PV = nRT \;\; \rightarrow \;\; P_{\text{a}} = \frac{nRT_{\text{a}}}{V_{\text{a}}} \;\; , \;\; P_{\text{b}} = \frac{nRT_{\text{b}}}{V_{\text{b}}} \;\; \rightarrow$$

$$\frac{nRT_{\text{a}}}{V_{\text{a}}}V_{\text{a}}^{\gamma} = \frac{nRT_{\text{b}}}{V_{\text{b}}}V_{\text{b}}^{\gamma} \;\; \rightarrow \;\; T_{\text{a}}V_{\text{a}}^{\gamma-1} = T_{\text{b}}V_{\text{b}}^{\gamma-1} \;\; \rightarrow \;\; \frac{V_{\text{a}}}{V_{\text{b}}} = \left(\frac{T_{\text{b}}}{T_{\text{a}}}\right)^{\frac{1}{\gamma-1}} = \left(\frac{273\,\text{K} + 430\,\text{K}}{273\,\text{K} + 25\,\text{K}}\right)^{\frac{1}{1.4-1}} = \boxed{8.55}$$

22. The ideal coefficient of performance is given by Eq. 20-4c.

$$\text{COP}_{\text{ideal}} = \frac{T_{\text{L}}}{T_{\text{H}} - T_{\text{L}}} = \frac{[273 + 3.0]\,\text{K}}{[22 - 3.0]\,\text{K}} = 14.53 \approx \boxed{15}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23. The ideal coefficient of performance for a refrigerator is given by Eq. 20-4c.

$$\text{COP} = \frac{T_\text{L}}{T_\text{H} - T_\text{L}} = \frac{(-15+273)\,\text{K}}{(33+273)\,\text{K} - (-15+273)\,\text{K}} = \boxed{5.4}$$

24. The COP for a heat pump is $\text{COP} = \dfrac{Q_\text{H}}{W}$ and the efficiency is $e = \dfrac{W}{Q_\text{H}}$. Thus they are reciprocals of each other. So if the efficiency is 0.38, the COP is $\dfrac{1}{0.38} = \boxed{2.6}$.

25. (*a*) The total rate of adding heat to the house by the heat pump must equal the rate of heat lost by conduction.

$$\frac{Q_\text{L} + W}{\Delta t} = (650\,\text{W/C°})(T_\text{in} - T_\text{out})$$

Since the heat pump is ideal, we have the following.

$$1 - \frac{T_\text{out}}{T_\text{in}} = 1 - \frac{Q_\text{L}}{Q_\text{H}} = 1 - \frac{Q_\text{L}}{Q_\text{L} + W} = \frac{W}{Q_\text{L} + W} \quad \rightarrow \quad Q_\text{L} + W = W\frac{T_\text{in}}{T_\text{in} - T_\text{out}}$$

Combine these two expressions, and solve for T_out.

$$\frac{Q_\text{L} + W}{\Delta t} = (650\,\text{W/C°})(T_\text{in} - T_\text{out}) = \frac{W}{\Delta t}\frac{T_\text{in}}{(T_\text{in} - T_\text{out})} \quad \rightarrow \quad (T_\text{in} - T_\text{out})^2 = \frac{W}{\Delta t}\frac{T_\text{in}}{(650\,\text{W/C°})} \quad \rightarrow$$

$$T_\text{out} = T_\text{in} - \sqrt{\frac{W}{\Delta t}\frac{T_\text{in}}{(650\,\text{W/C°})}} = 295\,\text{K} - \sqrt{(1500\,\text{W})\frac{295\,\text{K}}{(650\,\text{W/C°})}} = 269\,\text{K} = \boxed{-4°\text{C}}$$

(*b*) If the outside temperature is $8°\text{C}$, then the rate of heat loss by conduction is found to be $(650\,\text{W/C°})(14\,\text{C°}) = 9100\,\text{W}$. The heat pump must provide this much power to the house in order for the house to stay at a constant temperature. That total power is $(Q_\text{L} + W)/\Delta t$. Use this to solve for rate at which the pump must do work.

$$(Q_\text{L} + W)/\Delta t = \frac{W}{\Delta t}\left(\frac{T_\text{in}}{T_\text{in} - T_\text{out}}\right) = 9100\,\text{W} \quad \rightarrow$$

$$\frac{W}{\Delta t} = 9100\,\text{W}\left(\frac{T_\text{in} - T_\text{out}}{T_\text{in}}\right) = 9100\,\text{W}\left(\frac{14\,\text{K}}{295\,\text{K}}\right) = 432\,\text{W}$$

Since the maximum power the pump can provide is 1500 W, the pump must work $\dfrac{432\,\text{W}}{1500\,\text{W}} = 0.29$ or $\boxed{29\%}$ of the time.

26. The coefficient of performance for an ideal refrigerator is given by Eq. 20-4c, with temperatures in Kelvins. Use that expression to find the temperature inside the refrigerator.

$$\text{COP} = \frac{T_\text{L}}{T_\text{H} - T_\text{L}} \quad \rightarrow \quad T_\text{L} = T_\text{H}\frac{\text{COP}}{1 + \text{COP}} = [(32+273)\,\text{K}]\frac{5.0}{6.0} = 254\ \text{K} = \boxed{-19°\text{C}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27. The efficiency of a perfect Carnot engine is given by Eq. 20-1a and Eq. 20-3. Equate these two expressions to solve for the work required.

$$e = 1 - \frac{T_L}{T_H} = \ ; \ e = \frac{W}{Q_H} \ \rightarrow \ 1 - \frac{T_L}{T_H} = \frac{W}{Q_H} \ \rightarrow \ W = Q_H\left(1 - \frac{T_L}{T_H}\right)$$

(*a*) $$W = Q_H\left(1 - \frac{T_L}{T_H}\right) = (3100\,\text{J})\left(1 - \frac{0+273}{22+273}\right) = 231.2\,\text{J} \approx \boxed{230\,\text{J}}$$

(*b*) $$W = Q_H\left(1 - \frac{T_L}{T_H}\right) = (3100\,\text{J})\left(1 - \frac{-15+273}{22+273}\right) = 388.8\,\text{J} \approx \boxed{390\,\text{J}}$$

28. (*a*) Use Eq. 20-2.

$$\text{COP}_{\text{ideal}} = \frac{Q_L}{W} = \frac{Q_L}{Q_H - Q_L} = \frac{\frac{Q_L}{Q_H}}{\frac{Q_H}{Q_H} - \frac{Q_L}{Q_H}} = \frac{\frac{T_L}{T_H}}{1 - \frac{T_L}{T_H}} = \frac{\frac{T_L}{T_H}}{\frac{T_H}{T_H} - \frac{T_L}{T_H}} = \boxed{\frac{T_L}{T_H - T_L}}$$

(*b*) Use Eq. 20-3.

$$e = 1 - \frac{T_L}{T_H} \ \rightarrow \ \frac{T_L}{T_H} = 1 - e \ ; \ \text{COP}_{\text{ideal}} = \frac{\frac{T_L}{T_H}}{\frac{T_H}{T_H} - \frac{T_L}{T_H}} = \frac{1-e}{1-(1-e)} = \boxed{\frac{1-e}{e}}$$

(*c*) $$\text{COP}_{\text{ideal}} = \frac{T_L}{T_H - T_L} = \frac{(273-18)\,\text{K}}{42\,\text{K}} = \boxed{6.1}$$

29. (*a*) Use the coefficient of performance and the heat that is to be removed (Q_L) to calculate the work done. The heat that is to be removed is the amount of heat released by cooling the water, freezing the water, and cooling the ice. We calculate that heat as a positive quantity.

$$\text{COP}_{\text{ideal}} = \frac{Q_L}{W} = \frac{T_L}{T_H - T_L} \ \rightarrow$$

$$W = \frac{Q_L(T_H - T_L)}{T_L} = \frac{\left[mc_{H_2O}\Delta T_{\text{liquid}} + mL_{\text{fusion}} + mc_{\text{ice}}\Delta T_{\text{ice}}\right](T_H - T_L)}{T_L}$$

$$= \frac{(0.40\,\text{kg})\left[(4186\,\text{J/kg}\bullet°\text{C})(25\text{C}°) + 3.33\times10^5\,\text{J/kg} + (2100\,\text{J/kg}\bullet°\text{C})(17\text{C}°)\right](42\,\text{K})}{(273\,\text{K} - 17\,\text{K})}$$

$$= 3.106\times10^4\,\text{J} \approx \boxed{3.1\times10^4\,\text{J}}$$

(*b*) Now the compressor power (W/t) is given, and is to be related to the rate of removing heat from the freezer, Q_L/t.

$$\text{COP}_{\text{ideal}} = \frac{Q_L}{W} = \frac{Q_L/t}{W/t} = \frac{Q_L/t}{P} = \frac{T_L}{T_H - T_L} \ \rightarrow$$

$$t = \frac{Q_L(T_H - T_L)}{PT_L} = \frac{Q_L(T_H - T_L)}{PT_L} = \frac{\left[mc_{H_2O}\Delta T_{\text{liquid}} + mL_{\text{fusion}}\right](T_H - T_L)}{PT_L}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \frac{(0.40\,\text{kg})\left[(4186\,\text{J/kg}\cdot°\text{C})(25\text{C}°) + 3.33\times10^5\,\text{J/kg}\right](42\,\text{K})}{(180\,\text{W})(273\,\text{K} - 17\,\text{K})} = 159.6\,\text{s} \approx \boxed{2.7\,\text{min}}$$

30. (*a*) The ideal COP is given by Eq. 20-4c.

$$\text{COP} = \frac{T_\text{L}}{T_\text{H} - T_\text{L}} \quad \rightarrow \quad \text{COP}_\text{eff} = (0.20)\frac{T_\text{L}}{T_\text{H} - T_\text{L}} = (0.20)\frac{(273+24)\,\text{K}}{14\,\text{K}} = 4.243 \approx \boxed{4.2}$$

(*b*) The compressor power can be found from Eq. 20-4a.

$$\text{COP} = \frac{Q_\text{L}}{W} \quad \rightarrow \quad W = \frac{Q_\text{L}}{\text{COP}_\text{eff}} \quad \rightarrow$$

$$W/t = \frac{Q_\text{L}/t}{\text{COP}_\text{eff}} = \frac{\left(33{,}000\,\frac{\text{Btu}}{\text{h}}\right)\left(\frac{1055\,\text{J}}{\text{Btu}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)}{4.243}\left(\frac{1\,\text{kW}}{1000\,\text{W}}\right) = 2.279\,\text{kW} \approx \boxed{2.3\,\text{kW}}$$

(*c*) $2279\,\text{W}\left(\frac{1\,\text{hp}}{746\,\text{W}}\right) = \boxed{3.1\,\text{hp}}$

31. The coefficient of performance is the heat removed from the low-temperature area divided by the work done to remove the heat. In this case, the heat removed is the latent heat released by the freezing ice, and the work done is 1.2 kW times the elapsed time. The mass of water frozen is its density times its volume.

$$\text{COP} = \frac{Q_\text{L}}{W} = \frac{mL_\text{f}}{W} = \frac{\rho V L_\text{f}}{Pt} \quad \rightarrow$$

$$V = \frac{(\text{COP})Pt}{\rho L_\text{f}} = \frac{(7.0)(1200\,\text{W})(3600\,\text{s})}{(1.0\times10^3\,\text{kg/m}^3)(3.33\times10^5\,\text{J/kg})} = 0.0908\,\text{m}^3 \approx \boxed{91\,\text{L}}$$

32. Heat energy is taken away from the water, so the change in entropy will be negative. The heat transfer is the mass of the steam times the latent heat of vaporization.

$$\Delta S = \frac{Q}{T} = -\frac{mL_\text{vap}}{T} = -\frac{(0.25\,\text{kg})(22.6\times10^5\,\text{J/kg})}{(273+100)\,\text{K}} = \boxed{-1500\,\text{J/K}}$$

33. Energy has been made "unavailable" in the frictional stopping of the sliding box. We take that "lost" kinetic energy as the heat term of the entropy calculation.

$$\Delta S = Q/T = \tfrac{1}{2}mv_i^2/T = \tfrac{1}{2}(7.5\,\text{kg})(4.0\,\text{m/s})^2/293\,\text{K} = \boxed{0.20\,\text{J/K}}$$

Since this is a decrease in "availability," the entropy of the universe has increased.

34. Heat energy is taken away from the water, so the change in entropy will be negative. The heat taken away from the water is found from $\Delta Q = mL_\text{fusion}$. Note that 1.00 m^3 of water has a mass of $1.00\times10^3\,\text{kg}$.

$$\Delta S = \frac{Q}{T} = -\frac{mL_\text{fusion}}{T} = -\frac{(1.00\times10^3\,\text{kg})(3.33\times10^5\,\text{J/kg})}{273\,\text{K}} = \boxed{-1.22\times10^6\,\text{J/K}}$$

35. Because the temperature change is small, we can approximate any entropy integrals by $\Delta S = Q/T_{\text{avg}}$. There are three terms of entropy to consider. First, there is a loss of entropy from the water for the freezing process, ΔS_1. Second, there is a loss of entropy from that newly-formed ice as it cools to -10°C, ΔS_2. That process has an "average" temperature of -5°C. Finally, there is a gain of entropy by the "great deal of ice," ΔS_3, as the heat lost from the original mass of water in steps 1 and 2 goes into that great deal of ice. Since it is a large quantity of ice, we assume that its temperature does not change during the processes.

$$\Delta S_1 = \frac{Q_1}{T_1} = -\frac{mL_{\text{fusion}}}{T_1} = -\frac{\left(1.00\times10^3\,\text{kg}\right)\left(3.33\times10^5\,\text{J/kg}\right)}{273\,\text{K}} = -1.2198\times10^6\,\text{J/K}$$

$$\Delta S_2 = \frac{Q_2}{T_2} = -\frac{mc_{\text{ice}}\Delta T_2}{T_2} = -\frac{\left(1.00\times10^3\,\text{kg}\right)\left(2100\,\text{J/kg}\bullet\text{C}^{\circ}\right)\left(10\text{C}^{\circ}\right)}{\left(-5+273\right)\text{K}} = -7.8358\times10^4\,\text{J/K}$$

$$\Delta S_3 = \frac{Q_3}{T_3} = \frac{-Q_1 - Q_2}{T_3} = \frac{mL_{\text{fusion}} + mc_{\text{ice}}\Delta T_2}{T_3}$$

$$= \frac{\left(1.00\times10^3\,\text{kg}\right)\left[\left(3.33\times10^5\,\text{J/kg}\right) + \left(2100\,\text{J/kg}\bullet\text{C}^{\circ}\right)\left(10\text{C}^{\circ}\right)\right]}{\left(-10+273\right)\text{K}} = 1.3460\times10^6\,\text{J/K}$$

$$\Delta S = \Delta S_1 + \Delta S_2 + \Delta S_3 = -1.2198\times10^6\,\text{J/K} - 7.8358\times10^4\,\text{J/K} + 1.3460\times10^6\,\text{J/K}$$

$$= 4.784\times10^4\,\text{J/K} \approx \boxed{5\times10^4\,\text{J/K}}$$

36. (*a*) $\Delta S_{\text{water}} = \dfrac{Q_{\text{water}}}{T_{\text{water}}} = \dfrac{m_{\text{water}}L_{\text{vaporization}}}{T_{\text{water}}} = \dfrac{\left(0.45\,\text{kg}\right)\left(2.26\times10^6\,\text{J/kg}\right)}{373\,\text{K}} = 2727\,\text{J/K} \approx \boxed{2700\,\text{J/K}}$

(*b*) Because the heat to vaporize the water comes from the surroundings, and we assume that the temperature of the surroundings does not change, we have $\Delta S_{\text{surroundings}} = -\Delta S_{\text{water}} = \boxed{-2700\,\text{J/K}}$.

(*c*) The entropy change of the universe for a reversible process is $\Delta S_{\text{universe}} = \boxed{0}$.

(*d*) If the process were irreversible, we would have $\left|\Delta S_{\text{surroundings}}\right| < \Delta S_{\text{water}}$, because the temperature of the surroundings would increase, and so $\boxed{\Delta S_{\text{universe}} > 0}$.

37. The same amount of heat that leaves the high temperature heat source enters the low temperature body of water. The temperatures of the heat source and body of water are constant, so the entropy is calculated without integration.

$$\Delta S = \Delta S_1 + \Delta S_2 = -\frac{Q}{T_{\text{high}}} + \frac{Q}{T_{\text{low}}} = Q\left(\frac{1}{T_{\text{low}}} - \frac{1}{T_{\text{high}}}\right) \quad \rightarrow$$

$$\frac{\Delta S}{t} = \frac{Q}{t}\left(\frac{1}{T_{\text{low}}} - \frac{1}{T_{\text{high}}}\right) = \left(9.50\,\text{cal/s}\right)\left(\frac{4.186\,\text{J}}{1\,\text{cal}}\right)\left(\frac{1}{\left(22+273\right)\text{K}} - \frac{1}{\left(225+273\right)\text{ K}}\right)$$

$$= \boxed{5.49\times10^{-2}\,\frac{\text{J/K}}{\text{s}}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

38. The equilibrium temperature is found using calorimetry, from Chapter 19. The heat lost by the aluminum is equal to the heat gained by the water. We assume the Styrofoam insulates the mixture.

$$m_{\text{Al}}c_{\text{Al}}\left(T_{i\text{Al}}-T_f\right)=m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\left(T_f-T_{i\text{H}_2\text{O}}\right) \quad \rightarrow$$

$$T_f=\frac{m_{\text{Al}}c_{\text{Al}}T_{i\text{Al}}+m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}T_{i\text{H}_2\text{O}}}{m_{\text{Al}}c_{\text{Al}}+m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}}$$

$$=\frac{(2.8\text{ kg})(900\text{J/kg•C°})(43.0°\text{C})+(1.0\text{ kg})(4186\text{J/kg•C°})(20°\text{C})}{(2.8\text{ kg})(900\text{J/kg•C°})+(1.0\text{ kg})(4186\text{J/kg•C°})}=28.64°\text{C}$$

$$\Delta S=\Delta S_{\text{Al}}+\Delta S_{\text{H}_2\text{O}}=\int_{T_{\text{Al}}}^{T_{\text{final}}}\frac{dQ_{\text{Al}}}{T}+\int_{T_{\text{H}_2\text{O}}}^{T_{\text{final}}}\frac{dQ_{\text{H}_2\text{O}}}{T}=m_{\text{Al}}c_{\text{Al}}\int_{T_{\text{Al}}}^{T_{\text{final}}}\frac{dT}{T}+m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\int_{T_{\text{H}_2\text{O}}}^{T_{\text{final}}}\frac{dT}{T}$$

$$=m_{\text{Al}}c_{\text{Al}}\ln\frac{T_{\text{final}}}{T_{\text{Al}}}+m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\ln\frac{T_{\text{final}}}{T_{\text{H}_2\text{O}}}$$

$$=(2.8\text{kg})(900\text{J/kg•K})\ln\frac{(273.15+28.6)\text{K}}{(273.15+43.0)\text{K}}+(1.0\text{kg})(4186\text{J/kg•K})\ln\frac{(273.15+28.6)\text{K}}{(273.15+20.0)\text{K}}$$

$$=\boxed{4.4\text{J/K}}$$

39. Because the process happens at a constant temperature, we have $\Delta S=Q/T$. The heat flow can be found from the first law of thermodynamics, the work for expansion at a constant temperature, and the ideal gas equation

$$\Delta E_{\text{int}}=Q-W=0 \quad \rightarrow \quad Q=W=nRT\ln\frac{V_2}{V_1}=PV\ln\frac{P_1}{P_2} \quad \rightarrow$$

$$\Delta S=\frac{Q}{T}=\frac{PV}{T}\ln\frac{P_1}{P_2}=\frac{(7.5)\left(1.013\times10^5\text{Pa}\right)\left(2.50\times10^{-3}\text{m}^3\right)}{410\text{K}}\ln\frac{7.5\text{atm}}{1.0\text{atm}}=\boxed{9.3\text{J/K}}$$

40. (*a*) We find the final temperature of the system using calorimetry, and then approximate each part of the system as having stayed at an average constant temperature. We write both heat terms as positive and then set them equal to each other.

$$Q_{\text{lost}}=Q_{\text{gained}} \quad \rightarrow \quad m_{\text{hot}}c\left(T_{\text{hot}}-T_{\text{final}}\right)=m_{\text{cool}}c\left(T_{\text{final}}-T_{\text{cool}}\right) \quad \rightarrow$$

$$T_{\text{final}}=\frac{T_{\text{hot}}m_{\text{hot}}+T_{\text{cool}}m_{\text{cool}}}{m_{\text{cool}}+m_{\text{hot}}}=\frac{(38.0°\text{C})(3.0\text{kg})+(12.0°\text{C})(2.0\text{kg})}{5.0\text{kg}}=27.6°\text{C}$$

To calculate the entropy we must use the correctly signed heat terms.

$$\Delta S_{\text{cool}}=\frac{Q_{\text{cool}}}{T_{\substack{\text{cool}\\\text{avg}}}}=\frac{m_{\text{cool}}c\left(T_{\text{final}}-T_{\text{cool}}\right)}{\frac{1}{2}\left(T_{\text{cool}}+T_{\text{final}}\right)}=\frac{(2.0\text{kg})(4186\text{J/kg•K})(27.6°\text{C}-12.0°\text{C})}{\frac{1}{2}\left[(273\text{K}+12.0\text{K})+(273\text{K}+27.6\text{K})\right]}=446.0\text{J/kg}$$

$$\Delta S_{\text{hot}}=\frac{Q_{\text{hot}}}{T_{\substack{\text{hot}\\\text{avg}}}}=\frac{m_{\text{hot}}c\left(T_{\text{hot}}-T_{\text{final}}\right)}{\frac{1}{2}\left(T_{\text{hot}}+T_{\text{final}}\right)}=\frac{(3.0\text{kg})(4186\text{J/kg•K})(27.6-38.0°\text{C})}{\frac{1}{2}\left[(273\text{K}+38.0\text{K})+(273\text{K}+27.6\text{K})\right]}=-427.1\text{J/kg}$$

$$\Delta S=\Delta S_{\text{cool}}+\Delta S_{\text{hot}}=446.0\text{J/kg}-427.1\text{J/kg}=18.9\text{J/kg}\approx\boxed{19\text{J/kg}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We use the final temperature as found above, and then calculate the entropy changes by integration.

$$\Delta S_{\text{cool}} = \int \frac{dQ_{\text{cool}}}{T} = \int_{T_{\text{cool}}}^{T_{\text{final}}} \frac{m_{\text{cool}} c\, dT}{T} = m_{\text{cool}} c \ln \frac{T_{\text{final}}}{T_{\text{cool}}}$$

$$= (2.0\,\text{kg})(4186\,\text{J/kg•K}) \ln\left(\frac{273\,\text{K} + 27.6\,\text{K}}{273\,\text{K} + 12.0\,\text{K}}\right) = 446.2\,\text{J/kg}$$

$$\Delta S_{\text{hot}} = \int \frac{dQ_{\text{hot}}}{T} = \int_{T_{\text{hot}}}^{T_{\text{final}}} \frac{m_{\text{hot}} c\, dT}{T} = m_{\text{hot}} c \ln \frac{T_{\text{final}}}{T_{\text{hot}}}$$

$$= (3.0\,\text{kg})(4186\,\text{J/kg•K}) \ln\left(\frac{273\,\text{K} + 27.6\,\text{K}}{273\,\text{K} + 38.0\,\text{K}}\right) = -427.1\,\text{J/kg}$$

$$\Delta S = \Delta S_{\text{cool}} + \Delta S_{\text{hot}} = 446.2\,\text{J/kg} - 427.1\,\text{J/kg} = 19.1\,\text{J/kg} \approx \boxed{19\,\text{J/kg}}$$

Using the integrals only changed the answer by about 1%.

41. (*a*) The same amount of heat that leaves the room enters the ice and water.

$$\Delta S_{\text{melt}} = \frac{Q_{\text{melt}}}{T_{\text{melt}}} = \frac{mL_{\text{fusion}}}{T_{\text{melt}}} = m\frac{3.33\times10^5\,\text{J/kg}}{273\,\text{K}} = (1219.78m)\,\text{J/K}$$

$$\Delta S_{\text{warming}} = \int \frac{dQ_{\text{warming}}}{T} = \int_{T_{\text{melt}}}^{T_{\text{room}}} \frac{mc\,dT}{T} = mc \ln \frac{T_{\text{room}}}{T_{\text{melt}}} = m(4186\,\text{J/kg•K}) \ln \frac{293\,\text{K}}{273\,\text{K}} = (295.95m)\,\text{J/K}$$

$$\Delta S_{\text{room}} = \frac{-mL - mc(T_{\text{room}} - T_{\text{melt}})}{T_{\text{room}}} = -m\left[\frac{3.33\times10^5\,\text{J/kg} + (4186\,\text{J/kg•K})(20\,\text{K})}{293\,\text{K}}\right]$$

$$= (-1422.25m)\,\text{J/K}$$

$$\Delta S_{\text{total}} = \Delta S_{\text{melt}} + \Delta S_{\text{warming}} + \Delta S_{\text{room}} = (1219.78m)\,\text{J/K} + (295.95m)\,\text{J/K} - (1422.25m)\,\text{J/K}$$

$$= 93.48m\,\text{J/K} \approx \boxed{(93m)\,\text{J/K}}$$

This process will occur naturally. Note that we are assuming that *m* is in kg.

(*b*) For this situation, every heat exchange is exactly the opposite as in part (a). Thus we have $\Delta S_{\text{total}} \approx \boxed{(-93m)\,\text{J/K}}$. This will not occur naturally.

42. Since the process is at a constant volume, $dQ = nC_V dT$. For a diatomic gas in the temperature range of this problem, $C_V = \frac{5}{2}R$.

$$\Delta S = \int \frac{dQ}{T} = \int_{T_1}^{T_2} \frac{nC_V dT}{T} = \tfrac{5}{2} nR \ln \frac{T_2}{T_1} = \tfrac{5}{2}(2.0\,\text{mol})(8.314\,\text{J/mol•K}) \ln \frac{(273+55)\,\text{K}}{(273+25)\,\text{K}} = \boxed{4.0\,\text{J/K}}$$

43. (*a*) To approximate, we use the average temperature of the water.

$$\Delta S = \int \frac{dQ}{T} \approx \frac{\Delta Q}{T_{\text{avg}}} = \frac{mc\Delta T_{\text{water}}}{T_{\text{avg}}} = \frac{(1.00\,\text{kg})\left(4186\frac{\text{J}}{\text{kg•K}}\right)(75\text{C}^\circ)}{(273 + \frac{1}{2}75)\,\text{K}} = 1011\,\text{J/K} \approx \boxed{1010\,\text{J/K}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The heat input is given by $Q = mc\Delta T$, so $dQ = mcdT$.

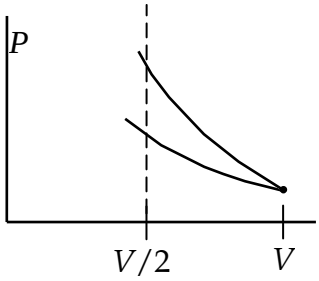
$$\Delta S = \int \frac{dQ}{T} = \int_{T_1}^{T_2} \frac{mcdT}{T} = mc \ln \frac{T_2}{T_1} = (1.00\,\text{kg})\left(4186 \frac{\text{J}}{\text{kg•K}}\right) \ln\left[\frac{(273+75)\,\text{K}}{(273)\,\text{K}}\right]$$

$$= 1016\,\text{J/K} \approx \boxed{1020\,\text{J/K}}$$

The approximation is only about 1% different.

(*c*) We assume that the temperature of the surroundings is constant at 75°C (the water was moved from a cold environment to a hot environment).

$$\Delta S = \int \frac{dQ}{T} = \frac{\Delta Q}{T} = \frac{-mc\Delta T_{\text{water}}}{T_{\text{surroundings}}} \frac{-(1.00\,\text{kg})\left(4186 \frac{\text{J}}{\text{kg•K}}\right)(-75\text{C}^\circ)}{(273+75)\,\text{K}} = \boxed{-900\,\text{J/K}} \text{ (2 sig. fig.)}$$



If instead the heating of the water were done reversibly, the entropy of the surroundings would decrease by 1020 J/K. For a general non-reversible case, the entropy of the surroundings would decrease, but by less than 1020 J/K (as in the calculation here).

44. Entropy is a state variable, and so the entropy difference between two states is the same for any path. Since we are told that states a and b have the same temperature, we may find the entropy change by calculating the change in entropy for an isothermal process connecting the same two states. We also use the first law of thermodynamics.

$$\Delta E_{\text{int}} = nC_V \Delta T = 0 = Q - W \quad \rightarrow \quad Q = W = nRT \ln\left(V_b/V_a\right)$$

$$\Delta S = \int \frac{dQ}{T} = \frac{Q}{T} = \frac{nRT \ln\left(V_b/V_a\right)}{T} = \boxed{nR \ln\left(V_b/V_a\right)}$$

45. (*a*) The figure shows two processes that start at the same state. The top process is adiabatic, and the bottom process is isothermic. We see from the figure that at a volume of *V*/2, the pressure is greater for the adiabatic process. We also prove it analytically.

Isothermal: $\dfrac{P_1V_1}{T_1} = \dfrac{P_2V_2}{T_2} \quad \rightarrow \quad P_2 = P_1 \dfrac{V_1}{V_2}\dfrac{T_2}{T_1} = P_1\left(\dfrac{V}{\frac{1}{2}V}\right)(1) = 2P_1$

Adiabatic: $P_1V_1^\gamma = P_2V_2^\gamma \quad \rightarrow \quad P_2 = P_1\left(\dfrac{V_1}{V_2}\right)^\gamma = P_1\left(\dfrac{V}{\frac{1}{2}V}\right)^\gamma = 2^\gamma P_1$

Since $\gamma > 1$, we see that $(P_2)_{\text{adiabatic}} > (P_2)_{\text{isothermic}}$. The ratio is $\dfrac{(P_2)_{\text{adiabatic}}}{(P_2)_{\text{isothermic}}} = \dfrac{2^\gamma P_1}{2P_1} = 2^{\gamma-1}$.

(*b*) For the adiabatic process: No heat is transferred to or from the gas, so $\Delta S_{\text{adiabatic}} = \int \dfrac{dQ}{T} = \boxed{0}$.

For the isothermal process: $\Delta E_{\substack{\text{int} \\ \text{isothermal}}} = 0 \quad \rightarrow \quad Q_{\text{isothermal}} = W_{\text{isothermal}} = nRT \ln\left(\dfrac{V_2}{V_1}\right)$

$$\Delta S_{\text{isothermal}} = \int \frac{dQ_{\text{isothermal}}}{T} = \frac{1}{T}\int dQ_{\text{isothermal}} = \frac{\Delta Q_{\text{isothermal}}}{T} = \frac{nRT \ln\left(V_2/V_1\right)}{T}$$

$$= nR \ln\left(V_2/V_1\right) = nR \ln\left(\tfrac{1}{2}\right) = \boxed{-nR \ln 2}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) Since each process is reversible, the energy change of the universe is 0, and so $\Delta S_{\text{surroundings}} = -\Delta S_{\text{system}}$. For the adiabatic process, $\Delta S_{\text{surroundings}} = \boxed{0}$. For the isothermal process, $\Delta S_{\text{surroundings}} = \boxed{nR\ln 2}$.

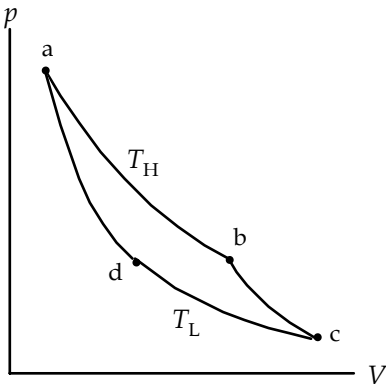
46. (*a*) The equilibrium temperature is found using calorimetry, from Chapter 19. The heat lost by the water is equal to the heat gained by the aluminum.

$$m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\left(T_{\text{H}_2\text{O}} - T_f\right) = m_{\text{Al}}c_{\text{Al}}\left(T_f - T_{\text{Al}}\right) \quad \rightarrow$$

$$T_f = \frac{m_{\text{Al}}c_{\text{Al}}T_{\text{Al}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}T_{\text{H}_2\text{O}}}{m_{\text{Al}}c_{\text{Al}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}}$$

$$= \frac{(0.150\,\text{kg})(900\,\text{J/kg•C°})(15°\text{C}) + (0.215\,\text{kg})(4186\,\text{J/kg•C°})(100°\text{C})}{(0.150\,\text{kg})(900\,\text{J/kg•C°}) + (0.215\,\text{kg})(4186\,\text{J/kg•C°})}$$

$$= 88.91°\text{C} = \boxed{89°\text{C}}$$



(*b*) $$\Delta S = \Delta S_{\text{Al}} + \Delta S_{\text{H}_2\text{O}} = \int_{T_{\text{Al}}}^{T_{\text{final}}} \frac{dQ_{\text{Al}}}{T} + \int_{T_{\text{H}_2\text{O}}}^{T_{\text{final}}} \frac{dQ_{\text{H}_2\text{O}}}{T} = m_{\text{Al}}c_{\text{Al}}\int_{T_{\text{Al}}}^{T_{\text{final}}} \frac{dT}{T} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\int_{T_{\text{H}_2\text{O}}}^{T_{\text{final}}} \frac{dT}{T}$$

$$= m_{\text{Al}}c_{\text{Al}}\ln\frac{T_{\text{final}}}{T_{\text{Al}}} + m_{\text{H}_2\text{O}}c_{\text{H}_2\text{O}}\ln\frac{T_{\text{final}}}{T_{\text{H}_2\text{O}}}$$

$$= (0.150\,\text{kg})(900\,\text{J/kg•K})\ln\frac{(273.15+88.91)\,\text{K}}{(273.15+15)\,\text{K}}$$

$$+ (0.215\,\text{kg})(4186\,\text{J/kg•K})\ln\frac{(273.15+88.91)\,\text{K}}{(273.15+100)\,\text{K}} = \boxed{3.7\,\text{J/K}}$$

47. (*a*) Entropy is a state function, which means that its value only depends on the state of the sample under consideration, not on its history of how it arrived at that state. A cyclical process starts and ends at the same state. Since the state is the same, the entropy is the same, and thus the change in entropy for the system is 0. Then, because all of the processes involved are reversible, the entropy change for the universe is 0, and so the entropy change for the surroundings must also be 0.

(*b*) For the two adiabatic processes, *Q* is constant. Thus $dS = \frac{dQ}{T} = 0$ for every infinitesimal part of an adiabatic path, and so $\Delta S_{\text{bc}} = \Delta S_{\text{da}} = 0$. For the two isothermic processes, we have the following, based on the first law of thermodynamics and Eq. 19-8.

$$\Delta E_{\text{int}} = Q - W = 0 \quad \rightarrow \quad Q_{\text{ab}} = W_{\text{ab}} = nRT_{\text{H}}\ln\frac{V_{\text{b}}}{V_{\text{a}}} \quad \rightarrow$$

$$\Delta S_{\text{ab}} = \int_{\text{state a}}^{\text{state b}} \frac{dQ}{T_{\text{H}}} = \frac{1}{T_{\text{H}}}\int_{\text{state a}}^{\text{state b}} dQ = \frac{Q_{\text{ab}}}{T_{\text{H}}} = \frac{nRT_{\text{H}}\ln\frac{V_{\text{b}}}{V_{\text{a}}}}{T_{\text{H}}} = nR\ln\frac{V_{\text{b}}}{V_{\text{a}}} \;\; ; \;\; \Delta S_{\text{cd}} = nR\ln\frac{V_{\text{d}}}{V_{\text{c}}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\Delta S_{\text{cycle}} = \Delta S_{\text{ab}} + \Delta S_{\text{cd}} = nR\ln\frac{V_{\text{b}}}{V_{\text{a}}} + nR\ln\frac{V_{\text{d}}}{V_{\text{c}}} = nR\ln\left(\frac{V_{\text{b}}}{V_{\text{a}}}\frac{V_{\text{d}}}{V_{\text{c}}}\right)$$

From the discussion on page 534, we see that $\frac{V_{\text{b}}}{V_{\text{a}}} = \frac{V_{\text{c}}}{V_{\text{d}}} \quad \rightarrow \quad \frac{V_{\text{b}}}{V_{\text{a}}}\frac{V_{\text{d}}}{V_{\text{c}}} = 1$. Thus

$$\Delta S_{\text{cycle}} = nR\ln\left(\frac{V_{\text{b}}}{V_{\text{a}}}\frac{V_{\text{d}}}{V_{\text{c}}}\right) = nR\ln 1 = 0.$$

48. (*a*) The gases do not interact since they are ideal, and so each gas expands to twice its volume with no change in temperature. Even though the actual process is not reversible, the entropy change can be calculated for a reversible process that has the same initial and final states. This is discussed in Example 20-7.

$$\Delta S_{\text{N}_2} = \Delta S_{\text{Ar}} = nR\ln\frac{V_2}{V_1} = nR\ln 2$$

$$\Delta S_{\text{total}} = \Delta S_{\text{N}_2} + \Delta S_{\text{Ar}} = 2nR\ln 2 = 2\left(1.00\,\text{mol}\right)\left(8.314\,\text{J/mol•K}\right)\ln 2 = \boxed{11.5\,\text{J/K}}$$

(*b*) Because the containers are insulated, no heat is transferred to or from the environment. Thus

$$\Delta S_{\text{surroundings}} = \int\frac{dQ}{T} = \boxed{0}.$$

(*c*) Let us assume that the argon container is twice the size of the nitrogen container. Then the final nitrogen volume is 3 times the original volume, and the final argon volume is 1.5 times the original volume.

$$\Delta S_{\text{N}_2} = nR\ln\left(\frac{V_2}{V_1}\right)_{\text{N}_2} = nR\ln 3 \;;\; \Delta S_{\text{Ar}} = nR\ln\left(\frac{V_2}{V_1}\right)_{\text{Ar}} = nR\ln 1.5$$

$$\Delta S_{\text{total}} = \Delta S_{\text{N}_2} + \Delta S_{\text{Ar}} = nR\ln 3 + nR\ln 1.5 = nR\ln 4.5 = \left(1.00\,\text{mol}\right)\left(8.314\,\text{J/mol•K}\right)\ln 4.5$$

$$= \boxed{12.5\,\text{J/K}}$$

49. For a system with constant volume, the heat input is given by Eq. 19-10a, $Q = nC_V\Delta T$. At temperature T, an infinitesimal amount of heat would result in an infinitesimal temperature change, related by $dQ = nC_V dT$. Use this with the definition of entropy.

$$dS = \frac{dQ}{T} = \frac{nC_V dT}{T} \quad \rightarrow \quad \frac{dT}{dS} = \frac{T}{nC_V}$$

This is exactly the definition of the slope of a process shown on a *T*–*S* graph, so the slope is $\boxed{\frac{T}{nC_V}}$.

A function with this property would be $T = T_0 e^{S/nC_V}$.

50. We assume that the process is reversible, so that the entropy change is given by Eq. 20-8. The heat transfer is given by $dQ = nC_V dT$.

$$S = \int_{T_1}^{T_2}\frac{dQ}{T} = \int_{T_1}^{T_2}\frac{nC_V dT}{T} = \int_{T_1}^{T_2}\frac{n\left(aT + bT^3\right)dT}{T} = \int_{T_1}^{T_2} n\left(a + bT^2\right)dT = n\left(aT + \tfrac{1}{3}bT^3\right)_{T_1}^{T_2}$$

$$= (0.15\,\text{mol})\left[\left(2.08\,\text{mJ/mol}\cdot\text{K}^2\right)(1.0\,\text{K} - 3.0\,\text{K}) + \tfrac{1}{3}\left(2.57\,\text{mJ/mol}\cdot\text{K}^4\right)\left[(1.0\,\text{K})^3 - (3.0\,\text{K})^3\right]\right]$$

$$= \boxed{-4.0\,\text{mJ/K}}$$

51. (*a*) Express the first law of thermodynamics in differential form, as given in Section 19-6.

$$dE_{\text{int}} = dQ - dW$$

For a reversible process, $dQ = TdS$ (Eq. 20-7), and for any process, $dW = PdV$. Also, since $\Delta E_{\text{int}} = nC_V \Delta T$, we have $dE_{\text{int}} = nC_V dT$. Finally, for an ideal gas, $P = \dfrac{nRT}{V}$.

$$dE_{\text{int}} = dQ - dW \;\rightarrow\; nC_V dT = TdS - PdV = TdS - \frac{nRT}{V}dV \;\rightarrow$$

$$TdS = nC_V dT + \frac{nRT}{V}dV \;\rightarrow\; \boxed{dS = nC_V \frac{dT}{T} + nR\frac{dV}{V}}$$

(*b*) Use the ideal gas law, the differentiation product rule, and Eq. 19-11, with the above result.

$$PV = nRT \;\rightarrow\; PdV + VdP = nRdT \;\rightarrow\; \frac{PdV}{nRT} + \frac{VdP}{nRT} = \frac{nRdT}{nRT} \;\rightarrow$$

$$\frac{PdV}{PV} + \frac{VdP}{PV} = \frac{dT}{T} \;\rightarrow\; \frac{dT}{T} = \frac{dV}{V} + \frac{dP}{P}$$

$$dS = nC_V \frac{dT}{T} + nR\frac{dV}{V} = nC_V\left(\frac{dV}{V} + \frac{dP}{P}\right) + nR\frac{dV}{V} = nC_V\frac{dP}{P} + n\left(C_V + R\right)\frac{dV}{V} \;\rightarrow$$

$$\boxed{dS = nC_V \frac{dP}{P} + nC_P \frac{dV}{V}}$$

(*c*) Let $dS = 0$ in the above result.

$$dS = nC_V \frac{dP}{P} + nC_P \frac{dV}{V} = 0 \;\rightarrow\; nC_V \frac{dP}{P} = -nC_P \frac{dV}{V} \;\rightarrow\; \frac{dP}{P} = -\frac{C_P}{C_V}\frac{dV}{V} = -\gamma\frac{dV}{V}$$

$$\int \frac{dP}{P} = -\gamma\int\frac{dV}{V} \;\rightarrow\; \ln P = -\gamma \ln V + \text{C} = \ln V^{-\gamma} + \text{C} \;\rightarrow\; e^{\ln P} = e^{\ln V^{-\gamma} + C} = e^{\ln V^{-\gamma}} e^C \;\rightarrow$$

$$P = V^{-\gamma}e^C \;\rightarrow\; \boxed{PV^\gamma = \text{constant}} = e^C$$

52. (*a*) The kinetic energy the rock loses when it hits the ground becomes a heat flow to the ground. That energy is then unavailable. We assume the temperature of the ground, T_{L}, does not change when the rock hits it.

$$\Delta S = \frac{\Delta Q}{T} = \frac{K}{T_{\text{L}}} \;\rightarrow\; E_{\text{lost}} = T_{\text{L}}\Delta S = T_{\text{L}}\left(\frac{K}{T_{\text{L}}}\right) = K$$

(*b*) The work done in a free expansion (which is isothermic if it is insulated) becomes unavailable as the gas expands. From Example 20-7, $\Delta S = nR\ln\dfrac{V_2}{V_1}$. The work done in an isothermal expansion is given in Eq. 19-8, as $W = nRT\ln\dfrac{V_2}{V_1}$. Since it is isothermal, $T = T_{\text{L}}$.

$$E_{\text{lost}} = T_{\text{L}}\Delta S = T_{\text{L}} nR\ln\left(V_2/V_1\right) = W$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) Assume an amount of heat Q_H is transferred from a high temperature reservoir T_H to a lower temperature reservoir T_L. The entropy change during that process is $\Delta S = \frac{Q_H}{T_L} - \frac{Q_H}{T_H}$. The energy "lost" is $T_L \Delta S = T_L \left(\frac{Q_H}{T_L} - \frac{Q_H}{T_H} \right) = Q_H \left(1 - \frac{T_L}{T_H} \right) = Q_H e_{\text{Carnot}} = W$. The work done during the process is no longer available to do any other work, and so has become unavailable to do work in some other process following the first process.

53. The total energy stored in the copper block is found from the heat flow that initially raised its temperature above the temperature of the surroundings.

$$Q = mc\Delta T = (3.5\,\text{kg})(390\,\text{J/kg•K})(200\,\text{K}) = 2.73\times10^5\,\text{J}$$

We find the entropy change assuming that amount of energy leaves the copper in a reversible process, and that amount of energy enters the surroundings. The temperature of the surroundings is assumed to be constant.

$$\Delta S_{\text{Cu}} = \int \frac{dQ}{T} = \int_{490\,\text{K}}^{290\,\text{K}} \frac{mcdT}{T} = mc \ln\left(\frac{290\,\text{K}}{490\,\text{K}}\right) = (3.5\,\text{kg})(390\,\text{J/kg•K}) \ln\left(\frac{290\,\text{K}}{490\,\text{K}}\right) = -716\,\text{J/K}$$

$$\Delta S_{\text{surroundings}} = \frac{Q}{T_{\text{surroundings}}} = \frac{mc\Delta T}{T_{\text{surroundings}}} = \frac{2.73\times10^5\,\text{J}}{290\,\text{K}} = 941\,\text{J/K} \;\; ; \;\; \Delta S = (941 - 716)\,\text{J/K} = 225\,\text{J/K}$$

$$E_{\text{lost}} = T_L \Delta S = (290\,\text{K})(225\,\text{J/K}) = 6.5\times10^4\,\text{J}$$

$$W_{\text{available}} = Q - E_{\text{lost}} = 2.73\times10^5\,\text{J} - 6.5\times10^4\,\text{J} = \boxed{2.1\times10^5\,\text{J}}$$

54. For four heads: $W = 1 \;\rightarrow\; \Delta S = k \ln W = (1.38\times10^{-23}\,\text{J/K}) \ln 1 = \boxed{0}$

For 3 heads, 1 tail: $W = 4 \;\rightarrow\; \Delta S = k \ln W = (1.38\times10^{-23}\,\text{J/K}) \ln 4 = \boxed{1.91\times10^{-23}\,\text{J/K}}$

For 2 heads, 2 tails: $W = 6 \;\rightarrow\; \Delta S = k \ln W = (1.38\times10^{-23}\,\text{J/K}) \ln 6 = \boxed{2.47\times10^{-23}\,\text{J/K}}$

For 1 head, 3 tails: $W = 4 \;\rightarrow\; \Delta S = k \ln W = (1.38\times10^{-23}\,\text{J/K}) \ln 4 = \boxed{1.91\times10^{-23}\,\text{J/K}}$

For four tails: $W = 1 \;\rightarrow\; \Delta S = k \ln W = (1.38\times10^{-23}\,\text{J/K}) \ln 1 = \boxed{0}$

55. From the table below, we see that there are a total of $2^6 = 64$ microstates.

Macrostate	Possible Microstates (H = heads, T = tails)						Number of Microstates
6 heads, 0 tails	H H H H H H						1
5 heads, 1 tails	H H H H H T	H H H H T H	H H H T H H	H H T H H H	H T H H H H	T H H H H H	6
4 heads, 2 tails	H H H H T T	H H H T H T	H H H T T H	H H T H H T	H T H H H T	T H H H H T	15
	H H H T T H	H H T H T H	H T H H T H	H T H T H H	T H H H T H	H H T T H H	
	H T H T H H	T H H T H H	H T T H H H	T H T H H H	T H T H T H	T T H H H H	
3 heads, 3 tails	H H H T T T	H H T H T T	H T H H T T	T H H H T T	H H T T H T	H T H T H T	20
	H T H T H T	T H H T H T	H T T H H T	T H T H H T	T H T T H H	T T H H H T	
	T T T H H H	T T H T H H	T H T T H H	H T T T H H	T T H H T H	T H T H T H	
	T H T H T H	H T T H T H	T H H T T H	H T H T T H	H H T T T H		
2 heads, 4 tails	T T T H H H	T T T H T H	T T H T T H	T H T T T H	H T T T T H		15
	T T T H H T	T T H T H T	T H T T H T	H T T T H T	T T H H T T		
	T H T H T T	H T T H T T	T H H T T T	H T H T T T	H H T T T T		
1 heads, 5 tails	T T T T T H	T T T T H T	T T T H T T	T T H T T T	T H T T T T	H T T T T T	6
0 heads, 6 tails	T T T T T T						1

(*a*) The probability of obtaining three heads and three tails is $\boxed{20/64}$ or $\boxed{5/16}$.

(*b*) The probability of obtaining six heads is $\boxed{1/64}$.

56. When throwing two dice, there are 36 possible microstates.

(*a*) The possible microstates that give a total of 7 are: (1)(6) , (2)(5) , (3)(4), (4)(3), (5)(2), and (6)(1). Thus the probability of getting a 7 is $6/36 = \boxed{1/6}$.

(*b*) The possible microstates that give a total of 11 are: (5)(6) and (6)(5). Thus the probability of getting an 11 is $2/36 = \boxed{1/18}$.

(*c*) The possible microstates that give a total of 4 are: (1)(3) , (2)(2) , and (3)(1). Thus the probability of getting a 5 is $3/36 = \boxed{1/12}$.

57. (*a*) There is only one microstate for 4 tails: TTTT. There are 6 microstates with 2 heads and 2 tails: HHTT, HTHT, HTTH, THHT, THTH, and TTHH. Use Eq. 20-14 to calculate the entropy change.

$$\Delta S = k\ln W_2 - k\ln W_1 = k\ln\frac{W_2}{W_1} = \left(1.38\times10^{-23}\ \text{J/K}\right)\ln 6 = \boxed{2.47\times10^{-23}\ \text{J/K}}$$

(*b*) Apply Eq. 20-14 again. There is only 1 final microstate, and about 1.0×10^{29} initial microstates.

$$\Delta S = k\ln W_2 - k\ln W_1 = k\ln\frac{W_2}{W_1} = \left(1.38\times10^{-23}\ \text{J/K}\right)\ln\left(\frac{1}{1.0\times10^{29}}\right) = \boxed{-9.2\times10^{-22}\ \text{J/K}}$$

(*c*) These changes are much smaller than those for ordinary thermodynamic entropy changes. For ordinary processes, there are many orders of magnitude more particles than we have considered in this problem. That leads to many more microstates and larger entropy values.

58. The number of microstates for macrostate A is $W_\text{A} = \dfrac{10!}{10!0!} = 1$. The number of microstates for macrostate B is $W_\text{B} = \dfrac{10!}{5!5!} = 252.$

(*a*) $\Delta S = k\ln W_B - k\ln W_A = k\ln\dfrac{W_B}{W_A} = \left(1.38\times10^{-23}\ \text{J/K}\right)\ln 252 = \boxed{7.63\times10^{-23}\ \text{J/K}}$

Since $\Delta S > 0$, this $\boxed{\text{can occur naturally}}$.

(*b*) $\Delta S = k\ln W_A - k\ln W_B = -k\ln\dfrac{W_B}{W_A} = -\left(1.38\times10^{-23}\ \text{J/K}\right)\ln 252 = \boxed{-7.63\times10^{-23}\ \text{J/K}}$

Since $\Delta S < 0$, this $\boxed{\text{cannot occur naturally}}$.

59. (*a*) Assume that there are no dissipative forces present, and so the energy required to pump the water to the lake is just the gravitational potential energy of the water.

$$U_\text{grav} = mgh = \left(1.35\times10^5\ \text{kg/s}\right)\left(10.0\,\text{h}\right)\left(9.80\,\text{m/s}^2\right)\left(135\,\text{m}\right) = 1.786\times10^9\ \text{W•h}$$

$$\approx \boxed{1.79\times10^6\ \text{kWh}}$$

(*b*) $\dfrac{\left(1.786\times10^6\ \text{kW•h}\right)(0.75)}{14\,\text{h}} = \boxed{9.6\times10^4\ \text{kW}}$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

60. The required area is $\left(22\dfrac{10^3\,\text{W•h}}{\text{day}}\right)\left(\dfrac{1\,\text{day}}{9\,\text{h Sun}}\right)\left(\dfrac{1\,\text{m}^2}{40\,\text{W}}\right)=61\,\text{m}^2\approx\boxed{60\,\text{m}^2}$. A small house with 1000 ft^2 of floor space, and a roof tilted at 30°, would have a roof area of $\left(1000\,\text{ft}^2\right)\left(\dfrac{1}{\cos 30^\circ}\right)\left(\dfrac{1\,\text{m}}{3.28\,\text{ft}}\right)^2=$ 110 m^2, which is about twice the area needed, and so $\boxed{\text{the cells would fit on the house}}$. But not all parts of the roof would have 9 hours of sunlight, so more than the minimum number of cells would be needed.

61. We assume that the electrical energy comes from the 100% effective conversion of the gravitational potential energy of the water.

$W=mgh\ \rightarrow$

$$P=\frac{W}{t}=\frac{m}{t}gh=\rho\frac{V}{t}gh=\left(1.00\times10^3\,\text{kg/m}^3\right)\left(32\,\text{m}^3\text{/s}\right)\left(9.80\,\text{m/s}^2\right)(38\,\text{m})=\boxed{1.2\times10^7\,\text{W}}$$

62. (*a*) Calculate the Carnot efficiency for an engine operated between the given temperatures.

$$e_{\text{ideal}}=1-\frac{T_\text{L}}{T_\text{H}}=1-\frac{(273+4)\,\text{K}}{(273+27)\,\text{K}}=0.077=\boxed{7.7\%}$$

(*b*) Such an engine might be feasible in spite of the low efficiency because of the large volume of "fuel" (ocean water) available. Ocean water would appear to be an "inexhaustible" source of heat energy. And the oceans are quite accessible.

(*c*) The pumping of water between radically different depths would probably move smaller sea-dwelling creatures from their natural location, perhaps killing them in the transport process. Mixing the water at different temperatures will also disturb the environment of sea-dwelling creatures. There is a significant dynamic of energy exchange between the ocean and the atmosphere, and so any changing of surface temperature water might affect at least the local climate, and perhaps also cause larger-scale climate changes.

63. The gas is diatomic, and so $\gamma=1.4$ and $C_V=\frac{5}{2}R$.

(*a*) Find the number of moles by applying the ideal gas law to state a.

$$P_\text{a}V_\text{a}=nRT_\text{a}\ \rightarrow\ n=\frac{P_\text{a}V_\text{a}}{RT_\text{a}}=\frac{\left(1.013\times10^5\,\text{Pa}\right)\left(0.010\,\text{m}^3\right)}{\left(8.314\,\text{J/mol•K}\right)(300\,\text{K})}=0.406\,\text{mol}\approx\boxed{0.41\,\text{mol}}$$

(*b*) Find T_c using the adiabatic relationship with the ideal gas law.

$$P_\text{c}V_\text{c}^\gamma=P_\text{a}V_\text{a}^\gamma\ \rightarrow\ \frac{nRT_\text{c}}{V_\text{c}}V_\text{c}^\gamma=\frac{nRT_\text{a}}{V_\text{a}}V_\text{a}^\gamma\ \rightarrow\ T_\text{c}V_\text{c}^{\gamma-1}=T_\text{a}V_\text{a}^{\gamma-1}\ \rightarrow$$

$$T_\text{c}=T_\text{a}\left(\frac{V_\text{a}}{V_\text{c}}\right)^{\gamma-1}=(300\,\text{K})(2)^{0.4}=396\,\text{K}\approx\boxed{400\,\text{K}}\,(2\text{ sig. fig.})$$

(*c*) This is a constant volume process.

$$Q_\text{bc}=nC_V\left(T_\text{c}-T_\text{b}\right)=\tfrac{5}{2}nR\left(T_\text{c}-T_\text{b}\right)=\tfrac{5}{2}(0.406\,\text{mol})\left(8.314\,\text{J/mol•K}\right)(96\,\text{K})$$

$$=810.1\,\text{J}\approx\boxed{810\,\text{J}}$$

(*d*) The work done by an isothermal process is given by Eq. 19-8.

$$W_\text{ab}=nRT\ln\frac{V_\text{b}}{V_\text{a}}=(0.406\,\text{mol})\left(8.314\,\text{J/mol•K}\right)(300\,\text{K})\ln\left(\frac{0.0050}{0.010}\right)=-702\,\text{J}\approx\boxed{-700\,\text{J}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*e*) Use the first law of thermodynamics, and the fact that $Q_{ca} = 0$.

$$\Delta E_{\text{int}}{}_{ca} = Q_{ca} - W_{ca} = -W_{ca} \quad \rightarrow$$

$$W_{ca} = -\Delta E_{\text{int}}{}_{ca} = -nC_V\Delta T = n\left(\tfrac{5}{2}R\right)\left(T_c - T_a\right) = \tfrac{5}{2}\left(0.406\,\text{mol}\right)\left(8.314\,\text{J/mol•K}\right)\left(396\,\text{K} - 300\,\text{K}\right)$$

$$= 810.1\,\text{J} \approx \boxed{810\,\text{J}}$$

(*f*) Heat is input to the gas only along path bc.

$$e = \frac{W}{Q_{\text{in}}} = \frac{W_{ca} + W_{ab}}{Q_{bc}} = \frac{810.1\,\text{J} - 702\,\text{J}}{810.1\,\text{J}} = \boxed{0.13}$$

(*g*) $e_{\text{Carnot}} = \dfrac{T_H - T_L}{T_H} = \dfrac{396\,\text{K} - 300\,\text{K}}{396\,\text{K}} = \boxed{0.24}$

64. (*a*) The equilibrium temperature is found using calorimetry, from Chapter 19. The heat lost by the water is equal to the heat gained by the aluminum.

$$m_{H_2O}c_{H_2O}\left(T_{H_2O} - T_f\right) = m_{Al}c_{Al}\left(T_f - T_{Al}\right) \quad \rightarrow$$

$$T_f = \frac{m_{Al}c_{Al}T_{Al} + m_{H_2O}c_{H_2O}T_{H_2O}}{m_{Al}c_{Al} + m_{H_2O}c_{H_2O}}$$

$$= \frac{\left(0.1265\,\text{kg}\right)\left(900\,\text{J/kg•C°}\right)\left(18.00°\text{C}\right) + \left(0.1325\,\text{kg}\right)\left(4186\,\text{J/kg•C°}\right)\left(46.25°\text{C}\right)}{\left(0.1265\,\text{kg}\right)\left(900\,\text{J/kg•C°}\right) + \left(0.1325\,\text{kg}\right)\left(4186\,\text{J/kg•C°}\right)} = \boxed{41.44°\text{C}}$$

(*b*) $\Delta S = \Delta S_{Al} + \Delta S_{H_2O} = \displaystyle\int_{T_{Al}}^{T_{\text{final}}} \frac{dQ_{Al}}{T} + \int_{T_{H_2O}}^{T_{\text{final}}} \frac{dQ_{H_2O}}{T} = m_{Al}c_{Al}\int_{T_{Al}}^{T_{\text{final}}} \frac{dT}{T} + m_{H_2O}c_{H_2O}\int_{T_{H_2O}}^{T_{\text{final}}} \frac{dT}{T}$

$$= m_{Al}c_{Al}\ln\frac{T_{\text{final}}}{T_{Al}} + m_{H_2O}c_{H_2O}\ln\frac{T_{\text{final}}}{T_{H_2O}}$$

$$= \left(0.1265\,\text{kg}\right)\left(900\,\text{J/kg•K}\right)\ln\frac{\left(273.15 + 41.44\right)\text{K}}{\left(273.15 + 18.00\right)\text{K}}$$

$$+ \left(0.1325\,\text{kg}\right)\left(4186\,\text{J/kg•K}\right)\ln\frac{\left(273.15 + 41.44\right)\text{K}}{\left(273.15 + 46.25\right)\text{K}} = \boxed{0.399\,\text{J/K}}$$

65. (*a*) For each engine, the efficiency is given by $e = 0.65e_{\text{Carnot}}$. Thus

$$e_1 = 0.65e_{C-1} = 0.65\left(1 - \frac{T_{L1}}{T_{H1}}\right) = 0.65\left[1 - \frac{\left(430 + 273\right)\text{K}}{\left(710 + 273\right)\text{K}}\right] = 0.185$$

$$e_2 = 0.65e_{C-2} = 0.65\left(1 - \frac{T_{L2}}{T_{H2}}\right) = 0.65\left[1 - \frac{\left(270 + 273\right)\text{K}}{\left(415 + 273\right)\text{K}}\right] = 0.137$$

For the first engine, the input heat is from the coal.

$W_1 = e_1Q_{H1} = e_1Q_{\text{coal}}$ and $Q_{L1} = Q_{H1} - W_1 = \left(1 - e_1\right)Q_{\text{coal}}$.

For the second energy, the input heat is the output heat from the first engine.

$W_2 = e_2Q_{H2} = e_2Q_{L1} = e_2\left(1 - e_1\right)Q_{\text{coal}}$

Add the two work expressions together, and solve for Q_{coal}.

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$W_1 + W_2 = e_1 Q_{\text{coal}} + e_2 (1 - e_1) Q_{\text{coal}} = (e_1 + e_2 - e_1 e_2) Q_{\text{coal}}$$

$$Q_{\text{coal}} = \frac{W_1 + W_2}{e_1 + e_2 - e_1 e_2} \quad \rightarrow \quad Q_{\text{coal}}/t = \frac{(W_1 + W_2)/t}{e_1 + e_2 - e_1 e_2}$$

Calculate the rate of coal use from the required rate of input energy, Q_{coal}/t.

$$Q_{\text{coal}}/t = \frac{950 \times 10^6 \text{ W}}{0.185 + 0.137 - (0.185)(0.137)} = 3.202 \times 10^9 \text{ J/s}$$

$$(3.202 \times 10^9 \text{ J/s}) \left(\frac{1 \text{ kg}}{2.8 \times 10^7 \text{ J}} \right) = 114.4 \text{ kg/s} \approx \boxed{110 \text{ kg/s}}$$

(*b*) The heat exhausted into the water will make the water temperature rise according to Eq. 19-2. The heat exhausted into water is the heat from the coal, minus the useful work.

$$Q_{\text{exhaust}} = Q_{\text{coal}} - W \; ; \; Q_{\text{exhaust}} = m_{\text{H}_2\text{O}} c_{\text{H}_2\text{O}} \Delta T_{\text{H}_2\text{O}} \quad \rightarrow \quad m_{\text{H}_2\text{O}} = \frac{Q_{\text{exhaust}}}{c_{\text{H}_2\text{O}} \Delta T_{\text{H}_2\text{O}}} = \frac{Q_{\text{coal}} - W}{c_{\text{H}_2\text{O}} \Delta T_{\text{H}_2\text{O}}} \quad \rightarrow$$

$$\frac{m_{\text{H}_2\text{O}}}{t} = \frac{(Q_{\text{coal}}/t) - (W/t)}{c_{\text{H}_2\text{O}} \Delta T_{\text{H}_2\text{O}}} = \frac{(3.202 \times 10^9 \text{ J/s}) - (9.50 \times 10^8) \text{ J/s}}{(4186 \text{ J/kg} \cdot \text{C}^\circ)(5.5 \text{C}^\circ)} = 9.782 \times 10^4 \text{ kg/s}$$

$$= \left(9.782 \times 10^4 \frac{\text{kg}}{\text{s}} \right) \left(3600 \frac{\text{s}}{\text{h}} \right) \left(\frac{1 \text{m}^3}{1000 \text{ kg}} \right) \left(\frac{1 \text{L}}{10^{-3} \text{m}^3} \right) \left(\frac{1 \text{gal}}{3.785 \text{ L}} \right) = \boxed{9.3 \times 10^7 \text{ gal/h}}$$

66. We start with Eq. 20-4a for the COP of a refrigerator. The heat involved is the latent heat of fusion for water.

$$\text{COP} = \frac{Q_{\text{L}}}{W} \quad \rightarrow \quad W = \frac{Q_{\text{L}}}{\text{COP}} \quad \rightarrow$$

$$W/t = \frac{Q_{\text{L}}/t}{\text{COP}} = \frac{5 \text{ tons}}{0.15 \text{COP}_{\text{ideal}}} = \frac{5(909 \text{ kg/d})(3.33 \times 10^5 \text{ J/kg})}{0.15 \left(\frac{273 \text{K} + 22 \text{K}}{13 \text{K}} \right)} = 4.446 \times 10^8 \text{ J/d}$$

$$\text{cost/h} = (4.446 \times 10^8 \text{ J/d}) \left(\frac{1 \text{d}}{24 \text{ h}} \right) \left(\frac{1 \text{kWh}}{3.600 \times 10^6 \text{ J}} \right) \left(\frac{\$0.10}{\text{kWh}} \right) = \boxed{\$0.51/\text{h}}$$

67. (*a*) The exhaust heating rate is found from the delivered power and the efficiency. Use the output energy with the relationship $Q = mc\Delta T = \rho V c \Delta T$ to calculate the volume of air that is heated.

$$e = W/Q_{\text{H}} = W/(Q_{\text{L}} + W) \quad \rightarrow \quad Q_{\text{L}} = W(1/e - 1) \quad \rightarrow$$

$$Q_{\text{L}}/t = W/t(1/e - 1) = (9.2 \times 10^8 \text{ W})(1/0.35 - 1) = 1.709 \times 10^9 \text{ W}$$

$$Q_{\text{L}} = mc\Delta T \quad \rightarrow \quad Q_{\text{L}}/t = \frac{mc\Delta T}{t} = \frac{\rho V c \Delta T}{t} \quad \rightarrow \quad V/t = \frac{(Q_{\text{L}}/t)}{\rho c \Delta T}$$

The change in air temperature is 7.0C°. The heated air is at a constant pressure of 1 atm.

$$V/t = \frac{(Q_{\text{L}}/t)t}{\rho c \Delta T} = \frac{(1.709 \times 10^9 \text{ W})(8.64 \times 10^4 \text{ s/day})}{(1.2 \text{ kg/m}^3)(1.0 \times 10^3 \text{ J/kg} \cdot \text{C}^\circ)(7.0 \text{C}^\circ)}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= 1.757\times10^{10}\ \text{m}^3/\text{day}\left(\frac{10^{-9}\text{km}^3}{1\ \text{m}^3}\right) = 17.57\ \text{km}^3/\text{day} \approx \boxed{18\ \text{km}^3/\text{day}}$$

(*b*) If the air is 200 m thick, find the area by dividing the volume by the thickness.

$$A = \frac{\text{Volume}}{\text{thickness}} = \frac{17.57\ \text{km}^3}{0.15\ \text{km}} = 117\ \text{km}^2 \approx \boxed{120\ \text{km}^2}$$

This would be a square of approximately 6 miles to a side. Thus the local climate for a few miles around the power plant might be heated significantly.

68. The COP for an ideal heat pump is found from Eq. 20-5.

(*a*) $\text{COP} = \dfrac{Q_\text{H}}{W} = \dfrac{Q_\text{H}}{Q_\text{H} - Q_\text{L}} = \dfrac{T_\text{H}}{T_\text{H} - T_\text{L}} = \dfrac{(24+273)\,\text{K}}{(24-11)\,\text{K}} = 22.85 \approx \boxed{23}$

(*b*) From Figure 20-11, The heat delivered from a heat pump is Q_H.

$$\text{COP} = \frac{Q_\text{H}}{W} \quad \rightarrow$$

$$Q_\text{H} = (W/t)(t)(\text{COP}) = (1400\,\text{W})(3600\,\text{s})(22.85) = 1.152\times10^8\,\text{J} \approx \boxed{1.2\times10^8\,\text{J}}$$

69. All of the processes are either constant pressure or constant volume, and so the heat input and output can be calculated with specific heats at constant pressure or constant volume. This tells us that heat is input when the temperature increases, and heat is exhausted when the temperature decreases. The lowest temperature will be the temperature at point b. We use the ideal gas law to find the temperatures.

$$PV = nRT \ \rightarrow\ T = \frac{PV}{nR} \ \rightarrow$$

$$T_\text{b} = \frac{P_0V_0}{nR},\ T_\text{a} = \frac{P_0(2V_0)}{nR} = 2T_\text{b},\ T_\text{c} = \frac{(3P_0)V_0}{nR} = 3T_\text{b},\ T_\text{d} = \frac{(3P_0)(2V_0)}{nR} = 6T_\text{b}$$

(*a*) process ab: $W_\text{ab} = P\Delta V = P_0(-V_0) = -P_0V_0\ ;\ Q_\text{ab} < 0$

process bc: $W_\text{bc} = P\Delta V = 0\ ;\ Q_\text{bc} = nC_V\Delta T = \frac{3}{2}nR(T_\text{c} - T_\text{b}) = \frac{3}{2}nR(2T_\text{b}) = \frac{3}{2}nR\left(2\dfrac{P_0V_0}{nR}\right) = 3P_0V_0$

process cd: $W_\text{bc} = P\Delta V = 3P_0V_0\ ;$

$$Q_\text{cd} = nC_P\Delta T = \tfrac{5}{2}nR(T_\text{d} - T_\text{c}) = \tfrac{5}{2}nR(3T_\text{b}) = \tfrac{5}{2}nR\left(3\frac{P_0V_0}{nR}\right) = \tfrac{15}{2}P_0V_0$$

process da: $W_\text{da} = P\Delta V = 0\ ;\ Q_\text{da} < 0$

$$e_\text{rectangle} = \frac{W}{Q_\text{H}} = \frac{3P_0V_0 - P_0V_0}{3P_0V_0 + \frac{15}{2}P_0V_0} = \frac{2}{\frac{21}{2}} = 0.1905 \approx \boxed{0.19}$$

(*b*) $e_\text{Carnot} = \dfrac{T_\text{H} - T_\text{L}}{T_\text{H}} = \dfrac{6T_\text{b} - T_\text{b}}{6T_\text{b}} = 0.8333\ ;\ \dfrac{e_\text{rectangle}}{e_\text{Carnot}} = \dfrac{0.1905}{0.8333} = \boxed{0.23}$

70. (*a*) Calculate the Carnot efficiency by $e = 1 - T_\text{L}/T_\text{H}$ and compare it to the 15% actual efficiency.

$$e_\text{Carnot} = 1 - T_\text{L}/T_\text{H} = 1 - (95+273)\,\text{K}/(495+273)\,\text{K} = 0.521 = 52.1\%$$

Thus the engine's relative efficiency is $e_\text{actual}/e_\text{Carnot} = 0.15/0.521 = 0.288 \approx \boxed{29\%}$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Take the stated 155 hp as the useful power obtained from the engine. Use the efficiency to calculate the exhaust heat.

$$P = \frac{W}{t} = (155\text{ hp})\left(\frac{746\text{ W}}{1\text{ hp}}\right) = 1.156\times10^5\text{ W} \approx \boxed{1.16\times10^5\text{ W}} \text{ (for moving the car)}$$

$$e = \frac{W}{Q_H} = \frac{W}{Q_L + W} \rightarrow$$

$$Q_L = W\left(\frac{1}{e} - 1\right) = Pt\left(\frac{1}{e} - 1\right) = (1.156\times10^5\text{ J/s})(1\text{ h})\left(\frac{3600\text{ s}}{1\text{ h}}\right)\left(\frac{1}{0.15} - 1\right)$$

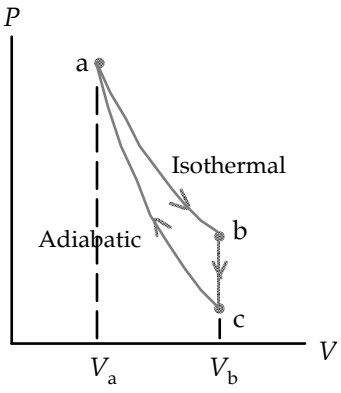
$$= 2.36\times10^9\text{ J} \approx \boxed{2.4\times10^9\text{ J}} = (2.36\times10^9\text{ J})\left(\frac{1\text{ kcal}}{4186\text{ J}}\right) = \boxed{5.6\times10^5\text{ kcal}}$$

71. (*a*) The exhaust heating rate can be found from the delivered power *P* and the Carnot efficiency. Then use the relationship between energy and temperature change, $Q = mc\Delta T$, to calculate the temperature change of the cooling water.

$$e = 1 - \frac{T_L}{T_H} = \frac{W}{Q_H} = \frac{W}{Q_L + W} \rightarrow Q_L = W\frac{T_L}{T_H - T_L} \rightarrow Q_L/t = W/t\,\frac{T_L}{T_H - T_L} = P\frac{T_L}{T_H - T_L}$$

$$Q_L = mc\Delta T \rightarrow Q_L/t = \frac{m}{t}c\Delta T = \rho\frac{V}{t}c\Delta T$$

Equate the two expressions for Q_L/t, and solve for ΔT.



$$P\frac{T_L}{T_H - T_L} = \rho\frac{V}{t}c\Delta T \rightarrow \Delta T = \frac{P}{\rho\dfrac{V}{t}c}\frac{T_L}{T_H - T_L}$$

$$= \frac{8.5\times10^8\text{ W}}{(1.0\times10^3\text{ kg/m}^3)(34\text{ m}^3\text{/s})(4186\text{ J/kg}\cdot\text{C}^\circ)}\frac{285\text{ K}}{(625\text{ K} - 285\text{ K})} = 5.006\text{ K} = \boxed{5.0\text{ C}^\circ}$$

(*b*) The addition of heat per kilogram for the downstream water is $Q_L/t = c\Delta T$.

$$\frac{\Delta S}{m} = \int\frac{dS}{m} = \int\frac{dQ}{mT} = \int\frac{cdT}{T} = c\int_{285\text{ K}}^{290\text{ K}}\frac{dT}{T} = (4186\text{ J/kg}\cdot\text{C}^\circ)\left(\ln\frac{290\text{ K}}{285\text{ K}}\right) = \boxed{72.8\text{ J/kg}\cdot\text{K}}$$

72. We have a monatomic gas, so $\gamma = \frac{5}{3}$. Also the pressure, volume, and temperature for state a are known. We use the ideal gas law, the adiabatic relationship, and the first law of thermodynamics.

(*a*) Use the ideal gas equation to relate states a and b. Use the adiabatic relationship to relate states a and c.

$$\frac{P_bV_b}{T_b} = \frac{P_aV_a}{T_a} \rightarrow$$

$$P_b = P_a\frac{V_a}{V_b}\frac{T_b}{T_a} = (1.00\text{ atm})\left(\frac{22.4\text{ L}}{56.0\text{ L}}\right)\left(\frac{273\text{ K}}{273\text{ K}}\right) = \boxed{0.400\text{ atm}}$$

$$P_aV_a^\gamma = P_cV_c^\gamma \rightarrow$$

$$P_c = P_a\left(\frac{V_a}{V_c}\right)^\gamma = (1.00\text{ atm})\left(\frac{22.4\text{ L}}{56.0\text{ L}}\right)^{5/3} = 0.2172\text{ atm} \approx \boxed{0.217\text{ atm}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Use the ideal gas equation to calculate the temperature at c.

$$\frac{P_b V_b}{T_b} = \frac{P_c V_c}{T_c} = \quad \rightarrow \quad T_c = T_b \frac{P_c}{P_b}\frac{V_c}{V_b} = (273\,\text{K})\left(\frac{0.2172\,\text{atm}}{0.400\,\text{atm}}\right)(1) = \boxed{148\,\text{K}}$$

(*c*) Process ab: $\Delta E_{\text{int}}_{\text{ab}} = nC_V\Delta T = \boxed{0}$;

$$Q_{ab} = W_{ab} = nRT\ln\frac{V_b}{V_a} = (1.00\,\text{mol})(8.314\,\text{J/mol•K})(273\,\text{K})\ln 2.5$$

$$= 2079.7\,\text{J} \approx \boxed{2080\,\text{J}}$$

$$\Delta S_{ab} = \frac{Q_{ab}}{T_{ab}} = \frac{2079.7\,\text{J}}{273\,\text{K}} = \boxed{7.62\,\text{J/K}}$$

Process bc: $W_{bc} = \boxed{0}$;

$$\Delta E_{\text{int}}_{\text{bc}} = Q_{bc} = nC_V\Delta T = (1.00\,\text{mol})\tfrac{3}{2}(8.314\,\text{J/mol•K})(148\,\text{K} - 273\,\text{K})$$

$$= -1559\,\text{J} \approx \boxed{-1560\,\text{J}}$$

$$\Delta S_{bc} = \int_b^c \frac{dQ}{T} = \int_{T_b}^{T_c} \frac{nC_V dT}{T} = nC_V \ln\frac{T_c}{T_b} = (1.00\,\text{mol})\tfrac{3}{2}(8.314\,\text{J/mol•K})\ln\frac{148\,\text{K}}{273\,\text{K}}$$

$$= \boxed{-7.64\,\text{J/K}}$$

Process ca: $Q_{ca} = \boxed{0}$; $\Delta S_{bc} = \boxed{0}$ (adiabatic) ;

$$\Delta E_{\text{int}}_{\text{ca}} = -W = -\Delta E_{\text{int}}_{\text{ab}} - \Delta E_{\text{int}}_{\text{bc}} = -0 - (-1560\,\text{J}) \quad \rightarrow$$

$$\Delta E_{\text{int}}_{\text{ca}} = \boxed{1560\,\text{J}} \ ; \ W_{ca} = \boxed{-1560\,\text{J}}$$

(*d*) $e = \dfrac{W}{Q_{\text{input}}} = \dfrac{2080\,\text{J} - 1560\,\text{J}}{2080\,\text{J}} = \boxed{0.25}$

73. Take the energy transfer to use as the initial kinetic energy of the cars, because this energy becomes "unusable" after the collision – it is transferred to the environment.

$$\Delta S = \frac{Q}{T} = \frac{2\left(\frac{1}{2}mv_i^2\right)}{T} = \frac{(1100\,\text{kg})\left[(75\,\text{km/h})\left(\frac{1\,\text{m/s}}{3.6\,\text{km/h}}\right)\right]^2}{(15+273)\,\text{K}} = \boxed{1700\,\text{J/K}}$$

74. (*a*) Multiply the power times the time times the mass per Joule relationship for the fat.

$$(95\,\text{J/s})(3600\,\text{s/h})(24\,\text{h/d})(1.0\text{ kg fat}/3.7\times10^7\,\text{J}) = 0.2218\,\text{kg/d} \approx \boxed{0.22\,\text{kg/d}}$$

(*b*) $1.0\text{ kg}(1\text{d}/0.2218\text{ kg}) = \boxed{4.5\text{d}}$

75. Heat will enter the freezer due to conductivity, at a rate given by 19-16b. This is the heat that must be removed from the freezer to keep it at a constant temperature, and so is the value of Q_L in the equation for the COP, Eq. 20-4a. The work in the COP is the work input by the cooling motor. The motor must remove the heat in 15% of the time that it takes for the heat to enter the freezer, so that it

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

only runs 15% of the time. To find the minimum power requirement, we assume the freezer is ideal in its operation.

$$\frac{Q_L}{t} = kA\frac{\Delta T}{\Delta x} \;;\; \text{COP} = \frac{Q_L}{W} = \frac{Q_L/t}{W/(0.15t)} = \frac{T_L}{T_H - T_L} \;\rightarrow$$

$$W/t = \frac{Q_L/t}{(0.15)}\left(\frac{T_H - T_L}{T_L}\right) = \frac{kA\dfrac{\Delta T}{\Delta x}}{(0.15)}\left(\frac{T_H - T_L}{T_L}\right) = \boxed{57\,\text{W}} \approx 0.076\,\text{hp}$$

76. The radiant energy is the heat to be removed at the low temperature. It can be related to the work necessary through the efficiency.

$$e = 1 - \frac{T_L}{T_H} = \frac{W}{Q_H} = \frac{W}{W + Q_L} \;\rightarrow\; W = Q_L\left(\frac{T_H}{T_L} - 1\right) \;\rightarrow\; W/t = Q_L/t\left(\frac{T_H}{T_L} - 1\right)$$

$$(W/t)_{3300} = (3300\text{ W})\left(\frac{T_H}{T_L} - 1\right) \qquad (W/t)_{500} = (500\text{ W})\left(\frac{T_H}{T_L} - 1\right)$$

$$(W/t)_{\text{savings}} = (W/t)_{3300} - (W/t)_{500} = (3300\,\text{W} - 500\,\text{W})\left(\frac{(273+32)\,\text{K}}{(273+21)\,\text{K}} - 1\right) = 104.8\text{W}$$

$$\approx \boxed{100\,\text{W}}\,(2\text{ sig. fig.})$$

77. We need to find the efficiency in terms of the given parameters, T_H, T_L, V_a, and V_b. So we must find the net work done and the heat input to the system. The work done during an isothermal process is given by Eq. 19-8. The work done during an isovolumentric process is 0. We also use the first law of thermodynamics.

ab (isothermal): $\Delta E_{\text{int}}{}_{\text{ab}} = 0 = Q_{\text{ab}} - W_{\text{ab}} \;\rightarrow\; Q_{\text{ab}} = W_{\text{ab}} = nRT_H \ln\frac{V_b}{V_a} > 0$

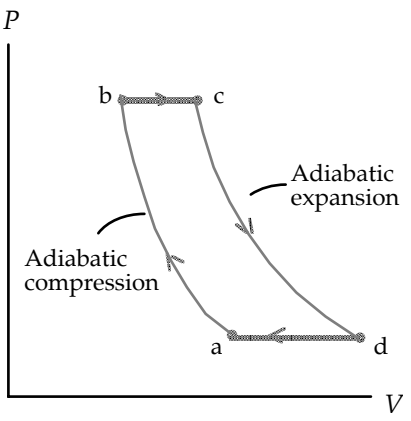
bc (isovolumetric): $\Delta E_{\text{int}}{}_{\text{bc}} = Q_{\text{bc}} - 0 \;\rightarrow\; Q_{\text{bc}} = \Delta E_{\text{int}}{}_{\text{bc}} = nC_V(T_L - T_H) = \frac{3}{2}nR(T_L - T_H) < 0$

cd (isothermal): $\Delta E_{\text{int}}{}_{\text{cd}} = 0 = Q_{\text{cd}} - W_{\text{cd}} \;\rightarrow\; Q_{\text{cd}} = W_{\text{cd}} = nRT_L \ln\frac{V_a}{V_b} = -nRT_L \ln\frac{V_b}{V_a} < 0$

da (isovolumetric): $\Delta E_{\text{int}}{}_{\text{da}} = Q_{\text{da}} - 0 \;\rightarrow\; Q_{\text{da}} = \Delta E_{\text{int}}{}_{\text{da}} = nC_V(T_H - T_L) = \frac{3}{2}nR(T_H - T_L) > 0$

$$W = W_{\text{ab}} + W_{\text{cd}} = nRT_H \ln\frac{V_b}{V_a} - nRT_L \ln\frac{V_b}{V_a} = nR(T_H - T_L)\ln\frac{V_b}{V_a}$$

$$Q_{\text{in}} = Q_{\text{ab}} + Q_{\text{da}} = nRT_H \ln\frac{V_b}{V_a} + \tfrac{3}{2}nR(T_H - T_L)$$



$$e_{\text{Sterling}} = \frac{W}{Q_{\text{in}}} = \frac{(T_H - T_L)\ln\dfrac{V_b}{V_a}}{T_H \ln\dfrac{V_b}{V_a} + \frac{3}{2}(T_H - T_L)} = \boxed{\left(\frac{T_H - T_L}{T_H}\right)\left[\frac{\ln\dfrac{V_b}{V_a}}{\ln\dfrac{V_b}{V_a} + \dfrac{3}{2}\left(\dfrac{T_H - T_L}{T_H}\right)}\right]}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= e_{\text{Carnot}}\left[\frac{\ln\dfrac{V_b}{V_a}}{\ln\dfrac{V_b}{V_a}+\dfrac{3}{2}\left(\dfrac{T_H-T_L}{T_H}\right)}\right]$$

Since the factor in [ ] above is less than 1, we see that $\boxed{e_{\text{Sterling}} < e_{\text{Carnot}}}$.

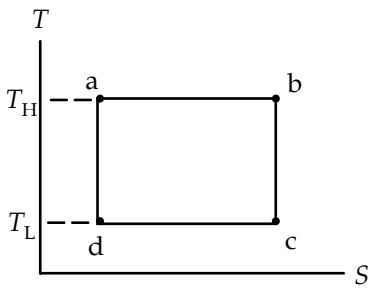
78. Since two of the processes are adiabatic, no heat transfer occurs in those processes. Thus the heat transfer must occur along the isobaric processes.

$$Q_H = Q_{bc} = nC_P(T_c - T_b) \;;\; Q_L = Q_{da} = nC_P(T_d - T_a)$$

$$e = 1 - \frac{Q_L}{Q_H} = 1 - \frac{nC_P(T_d - T_a)}{nC_P(T_c - T_b)} = 1 - \frac{(T_d - T_a)}{(T_c - T_b)}$$

Use the ideal gas relationship, which says that $PV = nRT$.

$$e = 1 - \frac{(T_d - T_a)}{(T_c - T_b)} = 1 - \frac{\left(\dfrac{P_dV_d}{nR} - \dfrac{P_aV_a}{nR}\right)}{\left(\dfrac{P_cV_c}{nR} - \dfrac{P_bV_b}{nR}\right)} = 1 - \frac{(P_dV_d - P_aV_a)}{(P_cV_c - P_bV_b)}$$



$$= 1 - \frac{P_a(V_d - V_a)}{P_b(V_c - V_b)}$$

Because process ab is adiabatic, we have $P_aV_a^\gamma = P_bV_b^\gamma \;\rightarrow\; V_a = V_b\left(\dfrac{P_b}{P_a}\right)^{1/\gamma}$. Because process cd is adiabatic, we have $P_bV_c^\gamma = P_aV_d^\gamma \;\rightarrow\; V_d = V_c\left(\dfrac{P_b}{P_a}\right)^{1/\gamma}$. Substitute these into the efficiency expression.

$$e = 1 - \frac{P_a(V_d - V_a)}{P_b(V_c - V_b)} = 1 - \frac{P_a\left(V_c\left(\dfrac{P_b}{P_a}\right)^{1/\gamma} - V_b\left(\dfrac{P_b}{P_a}\right)^{1/\gamma}\right)}{P_b(V_c - V_b)} = 1 - \frac{P_a\left(\dfrac{P_b}{P_a}\right)^{1/\gamma}(V_c - V_b)}{P_b(V_c - V_b)}$$

$$= 1 - \left(\frac{P_b}{P_a}\right)^{\frac{1}{\gamma}-1} = \boxed{1 - \left(\frac{P_b}{P_a}\right)^{\frac{1-\gamma}{\gamma}}}$$

79. (*a*) For the Carnot cycle, two of the processes are reversible adiabats, which are constant entropy processes. The other two processes are isotherms, at the low and high temperatures. See the adjacent diagram.

(*b*) The area underneath any path on the T-S diagram would be written as $\int T\,dS$. This integral is the heat involved in the process.

$$\int T\,dS = \int T\frac{dQ}{T} = \int dQ = Q_{\text{net}}$$

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For a closed cycle such as the Carnot cycle shown, since there is no internal energy change, the first law of thermodynamics says that $\int T\,dS = Q_{\text{net}} = \boxed{W_{\text{net}}}$, the same as $\int P\,dV$.

80. First we find the equilibrium temperature from calorimetry (section 19-4), and then calculate the entropy change of the system. The heat lost by the warm water must be equal to the heat gained by the cold water. Since the amounts of mass are the same, the equilibrium temperature is just the average of the two starting temperatures, 25°C.

$$\Delta S = \Delta S_{\substack{\text{cool}\\\text{water}}} + \Delta S_{\substack{\text{warm}\\\text{water}}} = \int_{\substack{T_{\text{initial}}\\\text{cool}}}^{T_{\text{final}}} \frac{dQ}{T} + \int_{\substack{T_{\text{initial}}\\\text{warm}}}^{T_{\text{final}}} \frac{dQ}{T} = \int_{273\,\text{K}}^{298\,\text{K}} \frac{mc\,dT}{T} + \int_{323\,\text{K}}^{298\,\text{K}} \frac{mc\,dT}{T} = mc\ln\left(\frac{298\,\text{K}}{273\,\text{K}}\right) + mc\ln\left(\frac{298\,\text{K}}{323\,\text{K}}\right)$$

$$= (4186\,\text{J/kg}\cdot^\circ\text{C})\left[\ln\left(\frac{298\,\text{K}}{273\,\text{K}}\right) + \ln\left(\frac{298\,\text{K}}{323\,\text{K}}\right)\right] = \boxed{13\,\text{J/kg}}$$

81. To find the mass of water removed, find the energy that is removed from the low temperature reservoir from the work input and the Carnot efficiency. Then use the latent heat of vaporization to determine the mass of water from the energy required for the condensation. Note that the heat of vaporization used is that given in section 19-5 for evaporation at 20°C.

$$e = 1 - \frac{T_{\text{L}}}{T_{\text{H}}} = \frac{W}{Q_{\text{H}}} = \frac{W}{W + Q_{\text{L}}} \quad \rightarrow \quad Q_{\text{L}} = W\frac{T_{\text{L}}}{(T_{\text{H}} - T_{\text{L}})} = mL_{\text{vapor}}$$

$$m = \frac{W}{L_{\text{vapor}}}\frac{T_{\text{L}}}{(T_{\text{H}} - T_{\text{L}})} = \frac{(650\,\text{W})(3600\,\text{s})}{(2.45\times10^6\,\text{J/kg})}\frac{(273+8)\,\text{K}}{(25-8)\ \text{K}} = 15.79\,\text{kg} \approx \boxed{16\,\text{kg}}$$

82. (*a*) From the table below, we see that there are 10 macrostates, and a total of 27 microstates.

Macrostate	Microstates (r = red, o = orange, g = green)			Number of Microstates
3 red, 0 orange, 0 green	r r r			1
2 red, 1 orange, 0 green	r r o	r o r	o r r	3
2 red, 0 orange, 1 green	r r g	r g r	g r r	3
1 red, 2 orange, 0 green	r o o	o r o	o o r	3
1 red, 0 orange, 2 green	r g g	g r g	g g r	3
1 red, 1 orange, 1 green	r o g o g r	r g o g r o	o r g g o r	6
0 red, 3 orange, 0 green	o o o			1
0 red, 2 orange, 1 green	g o o	o g o	o o g	3
0 red, 1 orange, 2 green	o g g	g o g	g g o	3
0 red, 0 orange, 3 green	g g g			1

(*b*) The probability of obtaining all 3 beans red is $\boxed{1/27}$.

(*c*) The probability of obtaining 2 greens and 1 orange is $\boxed{3/27}$ or $\boxed{1/9}$.

83. To do the numeric integration, first a value of ΔT is chosen. The temperature range is then partitioned into a series of individual temperatures, starting with 4 K, and each subsequent temperature an amount ΔT larger than the previous. So if $\Delta T = 1\,\text{K}$, then the temperatures used are 4 K, 5 K, 6 K, … 40 K. For each temperature above 4 K, an entropy change from the previous

© 2008 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

temperature is calculated by $dS \approx nC_V \Delta T$. The total entropy change ΔS is then the sum of the individual dS terms. The process could be written as $\Delta S = \sum_i \frac{nC_V \Delta T}{T_i}$, where $T_{i+1} = T_i + \Delta T$. For a value of $\Delta T = 1\text{K}$, a value of $\Delta S = 3.75\times10^{-3}\,\text{J/kg}$ was calculated, which is 3.7% larger than the analytic answer. So a smaller ΔT was chosen. For a value of $\Delta T = 0.5\,\text{K}$, a value of $\Delta S = 3.68\times10^{-3}\,\text{J/kg}$ was calculated, which is 1.9% larger than the analytic answer.

Here is the analytic calculation of the entropy change.

$$\Delta S = \int \frac{dQ}{T} = \int_{T_\text{L}}^{T_\text{H}} \frac{nC_V dT}{T} = \int_{T_\text{L}}^{T_\text{H}} \frac{n\left(1800\,\text{J}\bullet\text{mol}^{-1}\bullet\text{K}^{-1}\right)\left(T/T_\text{D}\right)^3 dT}{T}$$

$$= \left(1.00\,\text{mol}\right)\frac{\left(1800\,\text{J}\bullet\text{mol}^{-1}\bullet\text{K}^{-1}\right)}{T_\text{D}^3}\int_{4\,\text{K}}^{40\,\text{K}} T^2 dT = \frac{\left(1800\,\text{J}\bullet\text{K}^{-1}\right)}{\left(2230\,\text{K}\right)^3}\frac{1}{3}\left[\left(40\,\text{K}\right)^3 - \left(4\,\text{K}\right)^3\right]$$

$$= \boxed{3.61\times10^{-3}\,\text{J/kg}}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH20.XLS," on tab "Problem 20.83."

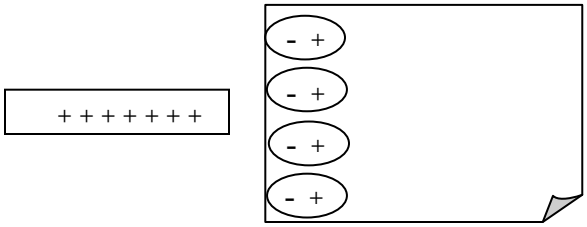
CHAPTER 21: Electric Charges and Electric Field



Responses to Questions

1. Rub a glass rod with silk and use it to charge an electroscope. The electroscope will end up with a net positive charge. Bring the pocket comb close to the electroscope. If the electroscope leaves move farther apart, then the charge on the comb is positive, the same as the charge on the electroscope. If the leaves move together, then the charge on the comb is negative, opposite the charge on the electroscope.

2. The shirt or blouse becomes charged as a result of being tossed about in the dryer and rubbing against the dryer sides and other clothes. When you put on the charged object (shirt), it causes charge separation within the molecules of your skin (see Figure 21-9), which results in attraction between the shirt and your skin.

3. Fog or rain droplets tend to form around ions because water is a polar molecule, with a positive region and a negative region. The charge centers on the water molecule will be attracted to the ions (positive to negative).

4. See also Figure 21-9 in the text. The negatively charged electrons in the paper are attracted to the positively charged rod and move towards it within their molecules. The attraction occurs because the negative charges in the paper are closer to the positive rod than are the positive charges in the paper, and therefore the attraction between the unlike charges is greater than the repulsion between the like charges.

5. A plastic ruler that has been rubbed with a cloth is charged. When brought near small pieces of paper, it will cause separation of charge in the bits of paper, which will cause the paper to be attracted to the ruler. On a humid day, polar water molecules will be attracted to the ruler and to the separated charge on the bits of paper, neutralizing the charges and thus eliminating the attraction.

6. The *net charge* on a conductor is the difference between the total positive charge and the total negative charge in the conductor. The "free charges" in a conductor are the electrons that can move about freely within the material because they are only loosely bound to their atoms. The "free electrons" are also referred to as "conduction electrons." A conductor may have a zero net charge but still have substantial free charges.

7. Most of the electrons are strongly bound to nuclei in the metal ions. Only a few electrons per atom (usually one or two) are free to move about throughout the metal. These are called the "conduction electrons." The rest are bound more tightly to the nucleus and are not free to move. Furthermore, in the cases shown in Figures 21-7 and 21-8, not all of the conduction electrons will move. In Figure 21-7, electrons will move until the attractive force on the remaining conduction electrons due to the incoming charged rod is balanced by the repulsive force from electrons that have already gathered at the left end of the neutral rod. In Figure 21-8, conduction electrons will be repelled by the incoming rod and will leave the stationary rod through the ground connection until the repulsive force on the remaining conduction electrons due to the incoming charged rod is balanced by the attractive force from the net positive charge on the stationary rod.

8. The electroscope leaves are connected together at the top. The horizontal component of this tension force balances the electric force of repulsion. (Note: The vertical component of the tension force balances the weight of the leaves.)

9. Coulomb's law and Newton's law are very similar in form. The electrostatic force can be either attractive or repulsive; the gravitational force can only be attractive. The electrostatic force constant is also much larger than the gravitational force constant. Both the electric charge and the gravitational mass are properties of the material. Charge can be positive or negative, but the gravitational mass only has one form.

10. The gravitational force between everyday objects on the surface of the Earth is extremely small. (Recall the value of G: 6.67×10^{-11} Nm^2/kg^2.) Consider two objects sitting on the floor near each other. They are attracted to each other, but the force of static fiction for each is much greater than the gravitational force each experiences from the other. Even in an absolutely frictionless environment, the acceleration resulting from the gravitational force would be so small that it would not be noticeable in a short time frame. We are aware of the gravitational force between objects if at least one of them is very massive, as in the case of the Earth and satellites or the Earth and you.

    The electric force between two objects is typically zero or close to zero because ordinary objects are typically neutral or close to neutral. We are aware of electric forces between objects when the objects are charged. An example is the electrostatic force (static cling) between pieces of clothing when you pull the clothes out of the dryer.

11. Yes, the electric force is a conservative force. Energy is conserved when a particle moves under the influence of the electric force, and the work done by the electric force in moving an object between two points in space is independent of the path taken.

12. Coulomb observed experimentally that the force between two charged objects is directly proportional to the charge on each one. For example, if the charge on either object is tripled, then the force is tripled. This is not in agreement with a force that is proportional to the *sum* of the charges instead of to the *product* of the charges. Also, a charged object is not attracted to or repelled from a neutral object, which would be the case if the numerator in Coulomb's law were proportional to the sum of the charges.

13. When a charged ruler attracts small pieces of paper, the charge on the ruler causes a separation of charge in the paper. For example, if the ruler is negatively charged, it will force the electrons in the paper to the edge of the paper farthest from the ruler, leaving the near edge positively charged. If the paper touches the ruler, electrons will be transferred from the ruler to the paper, neutralizing the positive charge. This action leaves the paper with a net negative charge, which will cause it to be repelled by the negatively charged ruler.

14. The test charges used to measure electric fields are small in order to minimize their contribution to the field. Large test charges would substantially change the field being investigated.

15. When determining an electric field, it is best, but not required, to use a positive test charge. A negative test charge would be fine for determining the magnitude of the field. But the direction of the electrostatic force on a negative test charge will be opposite to the direction of the electric field. The electrostatic force on a positive test charge will be in the same direction as the electric field. In order to avoid confusion, it is better to use a positive test charge.

16. See Figure 21-34b. A diagram of the electric field lines around two negative charges would be just like this diagram except that the arrows on the field lines would point towards the charges instead of away from them. The distance between the charges is *l*.

17. The electric field will be strongest to the right of the positive charge (between the two charges) and weakest to the left of the positive charge. To the right of the positive charge, the contributions to the field from the two charges point in the same direction, and therefore add. To the left of the positive charge, the contributions to the field from the two charges point in opposite directions, and therefore subtract. Note that this is confirmed by the density of field lines in Figure 21-34a.
18. At point C, the positive test charge would experience zero net force. At points A and B, the direction of the force on the positive test charge would be the same as the direction of the field. This direction is indicated by the arrows on the field lines. The strongest field is at point A, followed (in order of decreasing field strength) by B and then C.

19. Electric field lines can never cross because they give the direction of the electrostatic force on a positive test charge. If they were to cross, then the force on a test charge at a given location would be in more than one direction. This is not possible.

20. The field lines must be directed radially toward or away from the point charge (see rule 1). The spacing of the lines indicates the strength of the field (see rule 2). Since the magnitude of the field due to the point charge depends only on the distance from the point charge, the lines must be distributed symmetrically.

21. The two charges are located along a line as shown in the diagram.

(*a*) If the signs of the charges are opposite then the point on the line where $E = 0$ will lie to the left of Q. In that region the electric fields from the two charges will point in opposite directions, and the point will be closer to the smaller charge.

(*b*) If the two charges have the same sign, then the point on the line where $E = 0$ will lie between the two charges, closer to the smaller charge. In this region, the electric fields from the two charges will point in opposite directions.

22. The electric field at point P would point in the negative *x*-direction. The magnitude of the field would be the same as that calculated for a positive distribution of charge on the ring:

$$E = \frac{1}{4\pi\varepsilon_o}\frac{Qx}{\left(x^2 + a^2\right)^{3/2}}$$

23. The velocity of the test charge will depend on its initial velocity. The field line gives the direction of the change in velocity, not the direction of the velocity. The acceleration of the test charge will be along the electric field line.

24. The value measured will be slightly less than the electric field value at that point before the test charge was introduced. The test charge will repel charges on the surface of the conductor and these charges will move along the surface to increase their distances from the test charge. Since they will then be at greater distances from the point being tested, they will contribute a smaller amount to the field.

25. The motion of the electron in Example 21-16 is projectile motion. In the case of the gravitational force, the acceleration of the projectile is in the same direction as the field and has a value of *g*; in the case of an electron in an electric field, the direction of the acceleration of the electron and the field direction are opposite, and the value of the acceleration varies.

26. Initially, the dipole will spin clockwise. It will "overshoot" the equilibrium position (parallel to the field lines), come momentarily to rest and then spin counterclockwise. The dipole will continue to oscillate back and forth if no damping forces are present. If there are damping forces, the amplitude will decrease with each oscillation until the dipole comes to rest aligned with the field.

27. If an electric dipole is placed in a nonuniform electric field, the charges of the dipole will experience forces of different magnitudes whose directions also may not be exactly opposite. The addition of these forces will leave a net force on the dipole.

Solutions to Problems

1. Use Coulomb's law to calculate the magnitude of the force.

$$F = k\frac{Q_1Q_2}{r^2} = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(1.602\times10^{-19}\,\text{C}\right)\left(26\times1.602\times10^{-19}\,\text{C}\right)}{\left(1.5\times10^{-12}\,\text{m}\right)^2} = \boxed{2.7\times10^{-3}\,\text{N}}$$

2. Use the charge per electron to find the number of electrons.

$$\left(-38.0\times10^{-6}\,\text{C}\right)\left(\frac{1\text{ electron}}{-1.602\times10^{-19}\,\text{C}}\right) = \boxed{2.37\times10^{14}\,\text{electrons}}$$

3. Use Coulomb's law to calculate the magnitude of the force.

$$F = k\frac{Q_1Q_2}{r^2} = \left(8.988\times10^9\ \text{N}\bullet\text{m}^2/\text{C}^2\right)\frac{\left(25\times10^{-6}\,\text{C}\right)\left(2.5\times10^{-3}\,\text{C}\right)}{\left(0.28\,\text{m}\right)^2} = \boxed{7200\,\text{N}}$$

4. Use Coulomb's law to calculate the magnitude of the force.

$$F = k\frac{Q_1Q_2}{r^2} = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(1.602\times10^{-19}\,\text{C}\right)^2}{\left(4.0\times10^{-15}\,\text{m}\right)^2} = \boxed{14\,\text{N}}$$

5. The charge on the plastic comb is negative, so the comb has gained electrons.

$$\frac{\Delta m}{m} = \frac{\left(3.0\times10^{-6}\,\text{C}\right)\left(\frac{1\text{e}^-}{1.602\times10^{-19}\,\text{C}}\right)\left(\frac{9.109\times10^{-31}\,\text{kg}}{1\text{e}^-}\right)}{0.035\,\text{kg}} = 4.9\times10^{-16} = \boxed{4.9\times10^{-14}\%}$$

6. Since the magnitude of the force is inversely proportional to the square of the separation distance, $F \propto \frac{1}{r^2}$, if the distance is multiplied by a factor of 1/8, the force will be multiplied by a factor of 64.

$$F = 64F_0 = 64\left(3.2\times10^{-2}\,\text{N}\right) = \boxed{2.0\,\text{N}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

7. Since the magnitude of the force is inversely proportional to the square of the separation distance, $F \propto \dfrac{1}{r^2}$, if the force is tripled, the distance has been reduced by a factor of $\sqrt{3}$.

$$r = \frac{r_0}{\sqrt{3}} = \frac{8.45\text{ cm}}{\sqrt{3}} = \boxed{4.88\text{ cm}}$$

8. Use the charge per electron and the mass per electron.

$$\left(-46\times10^{-6}\text{C}\right)\left(\frac{1\text{ electron}}{-1.602\times10^{-19}\text{C}}\right) = 2.871\times10^{14} \approx \boxed{2.9\times10^{14}\text{ electrons}}$$

$$\left(2.871\times10^{14}\text{e}^-\right)\left(\frac{9.109\times10^{-31}\text{kg}}{1\text{ e}^-}\right) = \boxed{2.6\times10^{-16}\text{kg}}$$

9. To find the number of electrons, convert the mass to moles, the moles to atoms, and then multiply by the number of electrons in an atom to find the total electrons. Then convert to charge.

$$15\text{kg Au} = \left(15\text{kg Au}\right)\left(\frac{1\text{mole Al}}{0.197\text{kg}}\right)\left(\frac{6.022\times10^{23}\text{atoms}}{1\text{ mole}}\right)\left(\frac{79\text{electrons}}{1\text{molecule}}\right)\left(\frac{-1.602\times10^{-19}\text{C}}{\text{electron}}\right)$$

$$= \boxed{-5.8\times10^{8}\text{C}}$$

The net charge of the bar is $\boxed{0\text{C}}$, since there are equal numbers of protons and electrons.

10. Take the ratio of the electric force divided by the gravitational force.

$$\frac{F_\text{E}}{F_\text{G}} = \frac{k\dfrac{Q_1Q_2}{r^2}}{G\dfrac{m_1m_2}{r^2}} = \frac{kQ_1Q_2}{Gm_1m_2} = \frac{\left(8.988\times10^9\text{ N}\cdot\text{m}^2/\text{C}^2\right)\left(1.602\times10^{-19}\text{C}\right)^2}{\left(6.67\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2\right)\left(9.11\times10^{-31}\text{kg}\right)\left(1.67\times10^{-27}\text{kg}\right)} = \boxed{2.3\times10^{39}}$$

The electric force is about 2.3×10^{39} times stronger than the gravitational force for the given scenario.

11. (*a*) Let one of the charges be q, and then the other charge is $Q_\text{T} - q$. The force between the charges is $F_\text{E} = k\dfrac{q\left(Q_\text{T}-q\right)}{r^2} = \dfrac{k}{r^2}\left(qQ_\text{T}-q^2\right)$. To find the maximum and minimum force, set the first derivative equal to 0. Use the second derivative test as well.

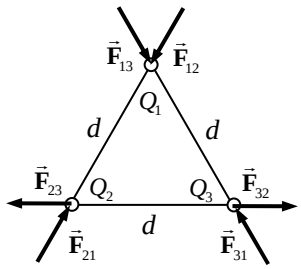
$$F_\text{E} = \frac{k}{r^2}\left(qQ_\text{T}-q^2\right)\ ;\ \frac{dF_\text{E}}{dq} = \frac{k}{r^2}\left(Q_\text{T}-2q\right) = 0\ \rightarrow\ q = \tfrac{1}{2}Q_\text{T}$$

$$\frac{d^2F_\text{E}}{dq^2} = -\frac{2k}{r^2} < 0\ \rightarrow\ q = \tfrac{1}{2}Q_\text{T}\text{ gives }\left(F_\text{E}\right)_\text{max}$$

So $\boxed{q_1 = q_2 = \tfrac{1}{2}Q_\text{T}}$ gives the maximum force.

(*b*) If one of the charges has all of the charge, and the other has no charge, then the force between them will be 0, which is the minimum possible force. So $\boxed{q_1 = 0,\ q_2 = Q_\text{T}}$ gives the minimum force.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



12. Let the right be the positive direction on the line of charges. Use the fact that like charges repel and unlike charges attract to determine the direction of the forces. In the following expressions, $k = 8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2$.

$$\vec{\mathbf{F}}_{+75} = -k\frac{(75\mu\text{C})(48\mu\text{C})}{(0.35\,\text{m})^2}\hat{\mathbf{i}} + k\frac{(75\mu\text{C})(85\mu\text{C})}{(0.70\,\text{m})^2}\hat{\mathbf{i}} = -147.2\,\text{N}\,\hat{\mathbf{i}} \approx \boxed{-150\,\text{N}\,\hat{\mathbf{i}}}$$

$$\vec{\mathbf{F}}_{+48} = k\frac{(75\mu\text{C})(48\mu\text{C})}{(0.35\,\text{m})^2}\hat{\mathbf{i}} + k\frac{(48\mu\text{C})(85\mu\text{C})}{(0.35\,\text{m})^2}\hat{\mathbf{i}} = 563.5\,\text{N}\,\hat{\mathbf{i}} \approx \boxed{560\,\text{N}\,\hat{\mathbf{i}}}$$

$$\vec{\mathbf{F}}_{-85} = -k\frac{(85\mu\text{C})(75\mu\text{C})}{(0.70\,\text{m})^2}\hat{\mathbf{i}} - k\frac{(85\mu\text{C})(48\mu\text{C})}{(0.35\,\text{m})^2}\hat{\mathbf{i}} = -416.3\,\text{N}\,\hat{\mathbf{i}} \approx \boxed{-420\,\text{N}\,\hat{\mathbf{i}}}$$

13. The forces on each charge lie along a line connecting the charges. Let the variable *d* represent the length of a side of the triangle. Since the triangle is equilateral, each angle is 60°. First calculate the magnitude of each individual force.

$$F_{12} = k\frac{|Q_1Q_2|}{d^2} = \left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(7.0\times10^{-6}\,\text{C})(8.0\times10^{-6}\,\text{C})}{(1.20\,\text{m})^2}$$

$$= 0.3495\,\text{N}$$

$$F_{13} = k\frac{|Q_1Q_3|}{d^2} = \left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(7.0\times10^{-6}\,\text{C})(6.0\times10^{-6}\,\text{C})}{(1.20\,\text{m})^2}$$

$$= 0.2622\,\text{N}$$

$$F_{23} = k\frac{|Q_2Q_3|}{d^2} = \left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(8.0\times10^{-6}\,\text{C})(6.0\times10^{-6}\,\text{C})}{(1.20\,\text{m})^2} = 0.2996\,\text{N} = F_{32}$$

Now calculate the net force on each charge and the direction of that net force, using components.

$$F_{1x} = F_{12x} + F_{13x} = -(0.3495\,\text{N})\cos60^\circ + (0.2622\,\text{N})\cos60^\circ = -4.365\times10^{-2}\,\text{N}$$

$$F_{1y} = F_{12y} + F_{13y} = -(0.3495\,\text{N})\sin60^\circ - (0.2622\,\text{N})\sin60^\circ = -5.297\times10^{-1}\,\text{N}$$

$$F_1 = \sqrt{F_{1x}^2 + F_{1y}^2} = \boxed{0.53\,\text{N}} \qquad \theta_1 = \tan^{-1}\frac{F_{1y}}{F_{1x}} = \tan^{-1}\frac{-5.297\times10^{-1}\,\text{N}}{-4.365\times10^{-2}\,\text{N}} = \boxed{265^\circ}$$

$$F_{2x} = F_{21x} + F_{23x} = (0.3495\,\text{N})\cos60^\circ - (0.2996\,\text{N}) = -1.249\times10^{-1}\,\text{N}$$

$$F_{2y} = F_{21y} + F_{23y} = (0.3495\,\text{N})\sin60^\circ + 0 = 3.027\times10^{-1}\,\text{N}$$

$$F_2 = \sqrt{F_{2x}^2 + F_{2y}^2} = \boxed{0.33\,\text{N}} \qquad \theta_2 = \tan^{-1}\frac{F_{2y}}{F_{2x}} = \tan^{-1}\frac{3.027\times10^{-1}\,\text{N}}{-1.249\times10^{-1}\,\text{N}} = \boxed{112^\circ}$$

$$F_{3x} = F_{31x} + F_{32x} = -(0.2622\,\text{N})\cos60^\circ + (0.2996\,\text{N}) = 1.685\times10^{-1}\,\text{N}$$

$$F_{3y} = F_{31y} + F_{32y} = (0.2622\,\text{N})\sin60^\circ + 0 = 2.271\times10^{-1}\,\text{N}$$

$$F_3 = \sqrt{F_{3x}^2 + F_{3y}^2} = \boxed{0.26\,\text{N}} \qquad \theta_3 = \tan^{-1}\frac{F_{3y}}{F_{3x}} = \tan^{-1}\frac{2.271\times10^{-1}\,\text{N}}{1.685\times10^{-1}\,\text{N}} = \boxed{53^\circ}$$

14. (*a*) If the force is repulsive, both charges must be positive since the total charge is positive. Call the total charge *Q*.

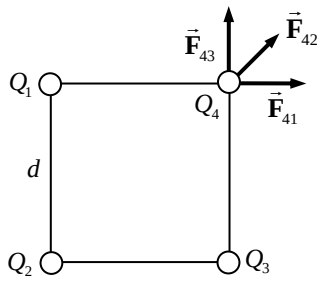
$$Q_1 + Q_2 = Q \qquad F = \frac{kQ_1Q_2}{d^2} = \frac{kQ_1(Q-Q_1)}{d^2} \;\rightarrow\; Q_1^2 - QQ_1 + \frac{Fd^2}{k} = 0$$

$$Q_1 = \frac{Q \pm \sqrt{Q^2 - 4\dfrac{Fd^2}{k}}}{2} = \frac{Q \pm \sqrt{Q^2 - 4\dfrac{Fd^2}{k}}}{2}$$

$$= \tfrac{1}{2}\left[\left(90.0\times10^{-6}\,\text{C}\right) \pm \sqrt{\left(90.0\times10^{-6}\,\text{C}\right)^2 - 4\frac{(12.0\,\text{N})(1.16\,\text{m})^2}{\left(8.988\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2\right)}}\right]$$

$$= \boxed{60.1\times10^{-6}\,\text{C},\ 29.9\times10^{-6}\,\text{C}}$$

(*b*) If the force is attractive, then the charges are of opposite sign. The value used for F must then be negative. Other than that, the solution method is the same as for part (*a*).



$$Q_1 + Q_2 = Q \qquad F = \frac{kQ_1Q_2}{d^2} = \frac{kQ_1(Q-Q_1)}{d^2} \;\rightarrow\; Q_1^2 - QQ_1 + \frac{Fd^2}{k} = 0$$

$$Q_1 = \frac{Q \pm \sqrt{Q^2 - 4\dfrac{Fd^2}{k}}}{2} = \frac{Q \pm \sqrt{Q^2 - 4\dfrac{Fd^2}{k}}}{2}$$

$$= \tfrac{1}{2}\left[\left(90.0\times10^{-6}\,\text{C}\right) \pm \sqrt{\left(90.0\times10^{-6}\,\text{C}\right)^2 - 4\frac{(-12.0\,\text{N})(1.16\,\text{m})^2}{\left(8.988\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2\right)}}\right]$$

$$= \boxed{106.8\times10^{-6}\,\text{C},\ -16.8\times10^{-6}\,\text{C}}$$

15. Determine the force on the upper right charge, and then use the symmetry of the configuration to determine the force on the other three charges. The force at the upper right corner of the square is the vector sum of the forces due to the other three charges. Let the variable d represent the 0.100 m length of a side of the square, and let the variable Q represent the 4.15 mC charge at each corner.

$$F_{41} = k\frac{Q^2}{d^2} \;\rightarrow\; F_{41x} = k\frac{Q^2}{d^2},\ F_{41y} = 0$$

$$F_{42} = k\frac{Q^2}{2d^2} \;\rightarrow\; F_{42x} = k\frac{Q^2}{2d^2}\cos45^\circ = k\frac{\sqrt{2}Q^2}{4d^2},\ F_{42y} = k\frac{\sqrt{2}Q^2}{4d^2}$$

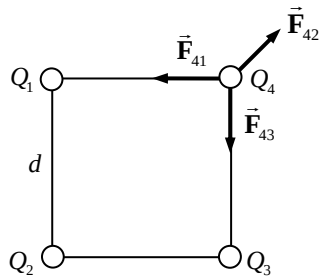
$$F_{43} = k\frac{Q^2}{d^2} \;\rightarrow\; F_{43x} = 0,\ F_{43y} = k\frac{Q^2}{d^2}$$

Add the *x* and *y* components together to find the total force, noting that $F_{4x} = F_{4y}$.

$$F_{4x} = F_{41x} + F_{42x} + F_{43x} = k\frac{Q^2}{d^2} + k\frac{\sqrt{2}Q^2}{4d^2} + 0 = k\frac{Q^2}{d^2}\left(1 + \frac{\sqrt{2}}{4}\right) = F_{4y}$$

$$F_4 = \sqrt{F_{4x}^2 + F_{4y}^2} = k\frac{Q^2}{d^2}\left(1 + \frac{\sqrt{2}}{4}\right)\sqrt{2} = k\frac{Q^2}{d^2}\left(\sqrt{2} + \frac{1}{2}\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$$= \left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(4.15\times10^{-3}\text{C}\right)^2}{\left(0.100\,\text{m}\right)^2}\left(\sqrt{2}+\frac{1}{2}\right) = \boxed{2.96\times10^{7}\ \text{N}}$$

$\theta = \tan^{-1}\dfrac{F_{4y}}{F_{4x}} = \boxed{45^\circ}$ above the *x*-direction.

For each charge, the net force will be the magnitude determined above, and will lie along the line from the center of the square out towards the charge.

16. Determine the force on the upper right charge, and then use the symmetry of the configuration to determine the force on the other charges.

The force at the upper right corner of the square is the vector sum of the forces due to the other three charges. Let the variable d represent the 0.100 m length of a side of the square, and let the variable Q represent the 4.15 mC charge at each corner.

$$F_{41} = k\frac{Q^2}{d^2} \;\rightarrow\; F_{41x} = -k\frac{Q^2}{d^2},\ F_{41y} = 0$$

$$F_{42} = k\frac{Q^2}{2d^2} \;\rightarrow\; F_{42x} = k\frac{Q^2}{2d^2}\cos45^\circ = k\frac{\sqrt{2}Q^2}{4d^2},\ F_{42y} = k\frac{\sqrt{2}Q^2}{4d^2}$$

$$F_{43} = k\frac{Q^2}{d^2} \;\rightarrow\; F_{43x} = 0,\ F_{43y} = -k\frac{Q^2}{d^2}$$

Add the *x* and *y* components together to find the total force, noting that $F_{4x} = F_{4y}$.

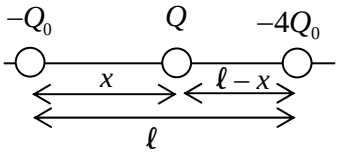
$$F_{4x} = F_{41x} + F_{42x} + F_{43x} = -k\frac{Q^2}{d^2} + k\frac{\sqrt{2}Q^2}{4d^2} + 0 = k\frac{Q^2}{d^2}\left(-1+\frac{\sqrt{2}}{4}\right) = -0.64645k\frac{Q^2}{d^2} = F_{4y}$$

$$F_4 = \sqrt{F_{4x}^2 + F_{4y}^2} = k\frac{Q^2}{d^2}\left(0.64645\right)\sqrt{2} = k\frac{Q^2}{d^2}\left(0.9142\right)$$

$$= \left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(4.15\times10^{-3}\text{C}\right)^2}{\left(0.100\,\text{m}\right)^2}\left(0.9142\right) = \boxed{1.42\times10^{7}\ \text{N}}$$

$\theta = \tan^{-1}\dfrac{F_{4y}}{F_{4x}} = \boxed{225^\circ}$ from the *x*-direction, or exactly towards the center of the square.

For each charge, there are two forces that point towards the adjacent corners, and one force that points away from the center of the square. Thus for each charge, the net force will be the magnitude of $\boxed{1.42\times10^{7}\ \text{N}}$ and will lie along the line from the charge inwards towards the center of the square.



17. The spheres can be treated as point charges since they are spherical, and so Coulomb's law may be used to relate the amount of charge to the force of attraction. Each sphere will have a magnitude *Q* of charge, since that amount was removed from one sphere and added to the other, being initially uncharged.

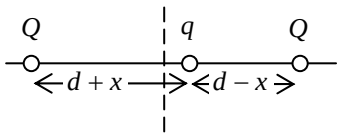
$$F = k\frac{Q_1Q_2}{r^2} = k\frac{Q^2}{r^2} \;\rightarrow\; Q = r\sqrt{\frac{F}{k}} = \left(0.12\ \text{m}\right)\sqrt{\frac{1.7\times10^{-2}\ \text{N}}{8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2}}$$

$$= 1.650\times10^{-7}\,\text{C}\left(\frac{1\ \text{electron}}{1.602\times10^{-19}\,\text{C}}\right) = \boxed{1.0\times10^{12}\ \text{electrons}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18. The negative charges will repel each other, and so the third charge must put an opposite force on each of the original charges. Consideration of the various possible configurations leads to the conclusion that the third charge must be positive and must be between the other two charges. See the diagram for the definition of variables.

For each negative charge, equate the magnitudes of the two forces on the charge. Also note that $0 < x < \ell$.



$$\text{left: } k\frac{Q_0 Q}{x^2} = k\frac{4Q_0^2}{\ell^2} \qquad \text{right: } k\frac{4Q_0 Q}{(\ell - x)^2} = k\frac{4Q_0^2}{\ell^2} \quad \rightarrow$$

$$k\frac{Q_0 Q}{x^2} = k\frac{4Q_0 Q}{(\ell - x)^2} \quad \rightarrow \quad x = \tfrac{1}{3}\ell$$

$$k\frac{Q_0 Q}{x^2} = k\frac{4Q_0^2}{\ell^2} \quad \rightarrow \quad Q = 4Q_0\frac{x^2}{\ell^2} = Q_0\frac{4}{(3)^2} = \tfrac{4}{9}Q_0$$

Thus the charge should be of magnitude $\boxed{\tfrac{4}{9}Q_0}$, and a distance $\boxed{\tfrac{1}{3}\ell \text{ from } -Q_0 \text{ towards } -4Q_0}$.

19. (*a*) The charge will experience a force that is always pointing towards the origin. In the diagram, there is a greater force of $\dfrac{Qq}{4\pi\varepsilon_0(d-x)^2}$ to the left, and a lesser force of $\dfrac{Qq}{4\pi\varepsilon_0(d+x)^2}$ to the right. So the net force is towards the origin. The same would be true if the mass were to the left of the origin. Calculate the net force.

$$F_{\text{net}} = \frac{Qq}{4\pi\varepsilon_0(d+x)^2} - \frac{Qq}{4\pi\varepsilon_0(d-x)^2} = \frac{Qq}{4\pi\varepsilon_0(d+x)^2(d-x)^2}\left[(d-x)^2 - (d+x)^2\right]$$

$$= \frac{-4Qqd}{4\pi\varepsilon_0(d+x)^2(d-x)^2}x = \frac{-Qqd}{\pi\varepsilon_0(d+x)^2(d-x)^2}x$$

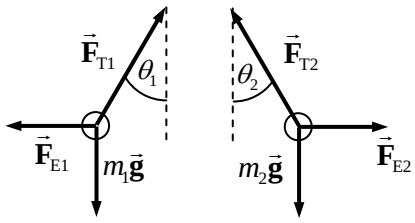
We assume that $x \ll d$.

$$F_{\text{net}} = \frac{-Qqd}{\pi\varepsilon_0(d+x)^2(d-x)^2}x \approx \frac{-Qq}{\pi\varepsilon_0 d^3}x$$

This has the form of a simple harmonic oscillator, where the "spring constant" is $k_{\text{elastic}} = \dfrac{Qq}{\pi\varepsilon_0 d^3}$.

The spring constant can be used to find the period. See Eq. 14-7b.

$$T = 2\pi\sqrt{\frac{m}{k_{\text{elastic}}}} = 2\pi\sqrt{\frac{m}{\frac{Qq}{\pi\varepsilon_0 d^3}}} = \boxed{2\pi\sqrt{\frac{m\pi\varepsilon_0 d^3}{Qq}}}$$



(*b*) Sodium has an atomic mass of 23.

$$T = 2\pi\sqrt{\frac{m\pi\varepsilon_0 d^3}{Qq}} = 2\pi\sqrt{\frac{(29)\left(1.66\times10^{-27}\,\text{kg}\right)\pi\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(3\times10^{-10}\,\text{m}\right)^3}{\left(1.60\times10^{-19}\,\text{C}\right)^2}}$$

$$= 2.4\times10^{-13}\,\text{s}\left(\frac{10^{12}\,\text{ps}}{1\,\text{s}}\right) = 0.24\,\text{ps} \approx \boxed{0.2\,\text{ps}}$$

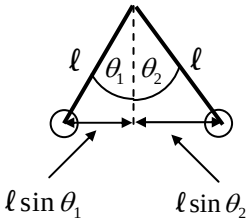
20. If all of the angles to the vertical (in both cases) are assumed to be small, then the spheres only have horizontal displacement, and so the electric force of repulsion is always horizontal. Likewise, the small angle condition leads to $\tan\theta \approx \sin\theta \approx \theta$ for all small angles. See the free-body diagram for each sphere, showing the three forces of gravity, tension, and the electrostatic force. Take to the right to be the positive horizontal direction, and up to be the positive vertical direction. Since the spheres are in equilibrium, the net force in each direction is zero.

(*a*) $\sum F_{1x} = F_{T1}\sin\theta_1 - F_{E1} = 0 \;\rightarrow\; F_{E1} = F_{T1}\sin\theta_1$

$$\sum F_{1y} = F_{T1}\cos\theta_1 - m_1 g \;\rightarrow\; F_{T1} = \frac{m_1 g}{\cos\theta_1} \;\rightarrow\; F_{E1} = \frac{m_1 g}{\cos\theta_1}\sin\theta_1 = m_1 g\tan\theta_1 = m_1 g\theta_1$$



A completely parallel analysis would give $F_{E2} = m_2 g\theta_2$. Since the electric forces are a Newton's third law pair, they can be set equal to each other in magnitude.

$$F_{E1} = F_{E2} \;\rightarrow\; m_1 g\theta_1 = m_2 g\theta_2 \;\rightarrow\; \theta_1/\theta_2 = m_2/m_1 = \boxed{1}$$

(*b*) The same analysis can be done for this case.

$$F_{E1} = F_{E2} \;\rightarrow\; m_1 g\theta_1 = m_2 g\theta_2 \;\rightarrow\; \theta_1/\theta_2 = m_1/m_1 = \boxed{2}$$

(*c*) The horizontal distance from one sphere to the other is s by the small angle approximation. See the diagram. Use the relationship derived above that $F_E = mg\theta$ to solve for the distance.

Case 1: $d = \ell(\theta_1 + \theta_2) = 2\ell\theta_1 \;\rightarrow\; \theta_1 = \dfrac{d}{2\ell}$

$$m_1 g\theta_1 = F_{E1} = \frac{kQ(2Q)}{d^2} = mg\frac{d}{2\ell} \;\rightarrow\; \boxed{d = \left(\frac{4\ell kQ^2}{mg}\right)^{1/3}}$$

Case 2: $d = \ell(\theta_1 + \theta_2) = \dfrac{3}{2}\ell\theta_1 \;\rightarrow\; \theta_1 = \dfrac{2d}{3\ell}$

$$m_1 g\theta_1 = F_{E1} = \frac{kQ(2Q)}{d^2} = mg\frac{2d}{3\ell} \;\rightarrow\; \boxed{d = \left(\frac{3\ell kQ^2}{mg}\right)^{1/3}}$$

21. Use Eq. 21–3 to calculate the force. Take east to be the positive *x* direction.

$$\vec{\mathbf{E}} = \frac{\vec{\mathbf{F}}}{q} \;\rightarrow\; \vec{\mathbf{F}} = q\vec{\mathbf{E}} = \left(-1.602\times10^{-19}\,\text{C}\right)\left(1920\,\text{N/C}\,\hat{\mathbf{i}}\right) = -3.08\times10^{-16}\,\text{N}\,\hat{\mathbf{i}} = \boxed{3.08\times10^{-16}\,\text{N west}}$$

22. Use Eq. 21–3 to calculate the electric field. Take north to be the positive *y* direction.

$$\vec{\mathbf{E}} = \frac{\vec{\mathbf{F}}}{q} = \frac{-2.18\times10^{-14}\,\text{N}\,\hat{\mathbf{j}}}{1.602\times10^{-19}\,\text{C}} = -1.36\times10^{5}\,\text{N/C}\,\hat{\mathbf{j}} = \boxed{1.36\times10^{5}\,\text{N/C south}}$$

23. Use Eq. 21–4a to calculate the electric field due to a point charge.

$$E = k\frac{Q}{r^2} = \left(8.988\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{33.0\times10^{-6}\,\text{C}}{(0.164\,\text{m})^2} = \boxed{1.10\times10^{7}\,\text{N/C up}}$$

Note that the electric field points away from the positive charge.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

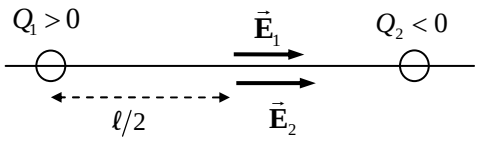
24. Use Eq. 21–3 to calculate the electric field.

$$\vec{\mathbf{E}} = \frac{\vec{\mathbf{F}}}{q} = \frac{8.4\,\text{N down}}{-8.8\times10^{-6}\,\text{C}} = \boxed{9.5\times10^{5}\,\text{N/C up}}$$

25. Use the definition of the electric field, Eq. 21-3.

$$\vec{\mathbf{E}} = \frac{\vec{\mathbf{F}}}{q} = \frac{\left(7.22\times10^{-4}\,\text{N}\,\hat{\mathbf{j}}\right)}{4.20\times10^{-6}\,\text{C}} = \boxed{172\,\text{N/C}\,\hat{\mathbf{j}}}$$

26. Use the definition of the electric field, Eq. 21-3.



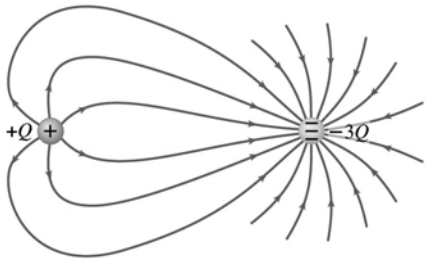
$$\vec{\mathbf{E}} = \frac{\vec{\mathbf{F}}}{q} = \frac{\left(3.0\hat{\mathbf{i}} - 3.9\hat{\mathbf{j}}\right)\times10^{-3}\,\text{N}}{1.25\times10^{-6}\,\text{C}} = \boxed{\left(2400\,\hat{\mathbf{i}} - 3100\,\hat{\mathbf{j}}\right)\text{N/C}}$$

27. Assuming the electric force is the only force on the electron, then Newton's second law may be used to find the acceleration.

$$\vec{\mathbf{F}}_{\text{net}} = m\vec{\mathbf{a}} = q\vec{\mathbf{E}} \;\rightarrow\; a = \frac{|q|}{m}E = \frac{\left(1.602\times10^{-19}\,\text{C}\right)}{\left(9.109\times10^{-31}\,\text{kg}\right)}\left(576\,\text{N/C}\right) = \boxed{1.01\times10^{14}\,\text{m/s}^2}$$

Since the charge is negative, the direction of the acceleration is $\boxed{\text{opposite to the field}}$.

28. The electric field due to the negative charge will point toward the negative charge, and the electric field due to the positive charge will point away from the positive charge. Thus both fields point in the same direction, towards the negative charge, and so can be added.



$$E = |E_1| + |E_2| = k\frac{|Q_1|}{r_1^2} + k\frac{|Q_2|}{r_2^2} = k\frac{|Q_1|}{(\ell/2)^2} + k\frac{|Q_2|}{(\ell/2)^2} = \frac{4k}{\ell^2}\left(|Q_1| + |Q_2|\right)$$

$$= \frac{4\left(8.988\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2\right)}{\left(0.080\,\text{m}\right)^2}\left(8.0\times10^{-6}\,\text{C} + 5.8\times10^{-6}\,\text{C}\right) = \boxed{7.8\times10^{7}\,\text{N/C}}$$

The direction is $\boxed{\text{towards the negative charge}}$.

29.

30. Assuming the electric force is the only force on the electron, then Newton's second law may be used to find the electric field strength.

$$F_{net} = ma = qE \;\rightarrow\; E = \frac{ma}{q} = \frac{\left(1.673\times10^{-27}\,\text{kg}\right)\left(1.8\times10^{6}\right)\left(9.80\,\text{m/s}^2\right)}{\left(1.602\times10^{-19}\,\text{C}\right)} = \boxed{0.18\,\text{N/C}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31. The field at the point in question is the vector sum of the two fields shown in Figure 21-56. Use the results of Example 21-11 to find the field of the long line of charge.

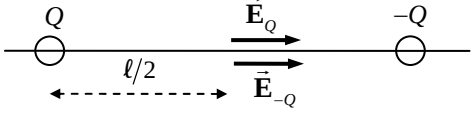
$$\vec{\mathbf{E}}_{\text{thread}} = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{y}\hat{\mathbf{j}} \;;\; \vec{\mathbf{E}}_Q = \frac{1}{4\pi\varepsilon_0}\frac{|Q|}{d^2}\left(-\cos\theta\hat{\mathbf{i}} - \sin\theta\hat{\mathbf{j}}\right) \;\rightarrow$$

$$\vec{\mathbf{E}} = \left(-\frac{1}{4\pi\varepsilon_0}\frac{|Q|}{d^2}\cos\theta\right)\hat{\mathbf{i}} + \left(\frac{1}{2\pi\varepsilon_0}\frac{\lambda}{y} - \frac{1}{4\pi\varepsilon_0}\frac{|Q|}{d^2}\sin\theta\right)\hat{\mathbf{j}}$$

$$d^2 = (0.070\,\text{m})^2 + (0.120\,\text{m})^2 = 0.0193\,\text{m}^2 \;;\; y = 0.070\,\text{m} \;;\; \theta = \tan^{-1}\frac{12.0\,\text{cm}}{7.0\,\text{cm}} = 59.7°$$

$$E_x = -\frac{1}{4\pi\varepsilon_0}\frac{|Q|}{d^2}\cos\theta = -\left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(2.0\,\text{C})}{0.0193\,\text{m}^2}\cos 59.7° = -4.699\times10^{11}\,\text{N/C}$$

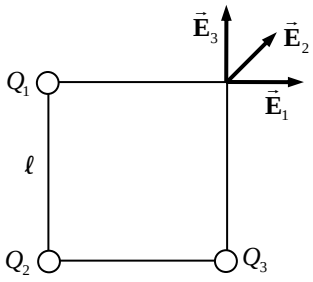
$$E_y = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{y} - \frac{1}{4\pi\varepsilon_0}\frac{|Q|}{d^2}\sin\theta = \frac{1}{4\pi\varepsilon_0}\left(\frac{2\lambda}{y} - \frac{|Q|}{d^2}\sin\theta\right)$$



$$= \left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\left[\frac{2(2.5\,\text{C/m})}{0.070\,\text{cm}} - \frac{(2.0\,\text{C})}{0.0193\,\text{m}^2}\sin 59.7°\right] = -1.622\times10^{11}\,\text{N/C}$$

$$\vec{\mathbf{E}} = \boxed{\left(-4.7\times10^{11}\,\text{N/C}\right)\hat{\mathbf{i}} + \left(-1.6\times10^{11}\,\text{N/C}\right)\hat{\mathbf{j}}}$$

$$E = \sqrt{E_x^2 + E_y^2} = \sqrt{\left(-4.699\times10^{11}\,\text{N/C}\right)^2 + \left(-1.622\times10^{11}\,\text{N/C}\right)^2} = \boxed{5.0\times10^{11}\,\text{N/C}}$$



$$\theta_E = \tan^{-1}\frac{\left(-1.622\times10^{11}\,\text{N/C}\right)}{\left(-4.699\times10^{11}\,\text{N/C}\right)} = \boxed{199°}$$

32. The field due to the negative charge will point towards the negative charge, and the field due to the positive charge will point towards the negative charge. Thus the magnitudes of the two fields can be added together to find the charges.

$$E_{\text{net}} = 2E_Q = 2k\frac{Q}{(\ell/2)^2} = \frac{8kQ}{\ell^2} \;\rightarrow\; Q = \frac{E\ell^2}{8k} = \frac{(586\,\text{N/C})(0.160\,\text{m})^2}{8\left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)} = \boxed{2.09\times10^{-10}\,\text{C}}$$

33. The field at the upper right corner of the square is the vector sum of the fields due to the other three charges. Let the variable ℓ represent the 1.0 m length of a side of the square, and let the variable Q represent the charge at each of the three occupied corners.

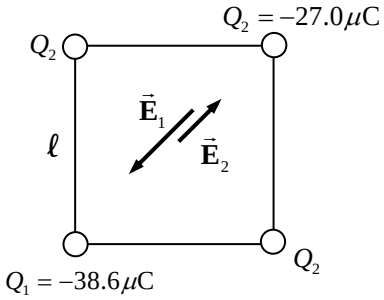
$$E_1 = k\frac{Q}{\ell^2} \;\rightarrow\; E_{1x} = k\frac{Q}{\ell^2}\,,\; E_{1y} = 0$$

$$E_2 = k\frac{Q}{2\ell^2} \;\rightarrow\; E_{2x} = k\frac{Q}{2\ell^2}\cos 45° = k\frac{\sqrt{2}Q}{4\ell^2}\,,\; E_{2y} = k\frac{\sqrt{2}Q}{4\ell^2}$$

$$E_3 = k\frac{Q}{\ell^2} \;\rightarrow\; E_{3x} = 0\,,\; E_{1y} = k\frac{Q}{\ell^2}$$

Add the *x* and *y* components together to find the total electric field, noting that $E_x = E_y$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



$$E_x = E_{1x} + E_{2x} + E_{3x} = k\frac{Q}{\ell^2} + k\frac{\sqrt{2}Q}{4\ell^2} + 0 = k\frac{Q}{\ell^2}\left(1 + \frac{\sqrt{2}}{4}\right) = E_y$$

$$E = \sqrt{E_x^2 + E_y^2} = k\frac{Q}{\ell^2}\left(1 + \frac{\sqrt{2}}{4}\right)\sqrt{2} = k\frac{Q}{\ell^2}\left(\sqrt{2} + \frac{1}{2}\right)$$

$$= \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(2.25\times10^{-6}\text{C}\right)}{\left(1.22\,\text{m}\right)^2}\left(\sqrt{2} + \frac{1}{2}\right) = \boxed{2.60\times10^4\ \text{N/C}}$$

$$\theta = \tan^{-1}\frac{E_y}{E_x} = \boxed{45.0^\circ}\ \text{from the } x\text{-direction.}$$

34. The field at the center due to the two $-27.0\,\mu$C negative charges on opposite corners (lower right and upper left in the diagram) will cancel each other, and so only the other two charges need to be considered. The field due to each of the other charges will point directly toward the charge. Accordingly, the two fields are in opposite directions and can be combined algebraically.

$$E = E_1 - E_2 = k\frac{|Q_1|}{\ell^2/2} - k\frac{|Q_2|}{\ell^2/2} = k\frac{|Q_1| - |Q_2|}{\ell^2/2}$$

$$= \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(38.6 - 27.0\right)\times10^{-6}\text{C}}{\left(0.525\,\text{m}\right)^2/2}$$

$$= \boxed{7.57\times10^6\ \text{N/C, towards the } -38.6\,\mu\text{C charge}}$$

35. Choose the rightward direction to be positive. Then the field due to $+Q$ will be positive, and the field due to $-Q$ will be negative.

$$E = k\frac{Q}{\left(x+a\right)^2} - k\frac{Q}{\left(x-a\right)^2} = kQ\left(\frac{1}{\left(x+a\right)^2} - \frac{1}{\left(x-a\right)^2}\right) = \boxed{\frac{-4kQxa}{\left(x^2-a^2\right)^2}}$$

The negative sign means the field points to the $\boxed{\text{left}}$.

36. For the net field to be zero at point P, the magnitudes of the fields created by Q_1 and Q_2 must be equal. Also, the distance x will be taken as positive to the left of Q_1. That is the only region where the total field due to the two charges can be zero. Let the variable ℓ represent the 12 cm distance, and note that $|Q_1| = \frac{1}{2}Q_2$.

$$\left|\vec{\mathbf{E}}_1\right| = \left|\vec{\mathbf{E}}_2\right| \quad\rightarrow\quad k\frac{|Q_1|}{x^2} = k\frac{Q_2}{\left(x+\ell\right)^2} \quad\rightarrow$$

$$x = \ell\frac{\sqrt{|Q_1|}}{\left(\sqrt{Q_2} - \sqrt{|Q_1|}\right)} = \left(12\,\text{cm}\right)\frac{\sqrt{25\,\mu\text{C}}}{\left(\sqrt{45\,\mu\text{C}} - \sqrt{25\,\mu\text{C}}\right)} = \boxed{35\,\text{cm}}$$

37. Make use of Example 21-11. From that, we see that the electric field due to the line charge along the y axis is $\vec{\mathbf{E}}_1 = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{x}\hat{\mathbf{i}}$. In particular, the field due to that line of charge has no y dependence. In a similar fashion, the electric field due to the line charge along the x axis is $\vec{\mathbf{E}}_2 = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{y}\hat{\mathbf{j}}$. Then the total field at (x, y) is the vector sum of the two fields.

$$\vec{\mathbf{E}} = \vec{\mathbf{E}}_1 + \vec{\mathbf{E}}_2 = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{x}\hat{\mathbf{i}} + \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{y}\hat{\mathbf{j}} = \frac{\lambda}{2\pi\varepsilon_0}\left(\frac{1}{x}\hat{\mathbf{i}} + \frac{1}{y}\hat{\mathbf{j}}\right)$$

$$E = \frac{\lambda}{2\pi\varepsilon_0}\sqrt{\frac{1}{x^2}+\frac{1}{y^2}} = \boxed{\frac{\lambda}{2\pi\varepsilon_0 xy}\sqrt{x^2+y^2}} \;;\; \theta = \tan^{-1}\frac{E_y}{E_x} = \tan^{-1}\frac{\frac{1}{2\pi\varepsilon_0}\frac{\lambda}{y}}{\frac{1}{2\pi\varepsilon_0}\frac{\lambda}{x}} = \boxed{\tan^{-1}\frac{x}{y}}$$

38. (*a*) The field due to the charge at A will point straight downward, and the field due to the charge at B will point along the line from A to the origin, 30° below the negative x axis.

$$E_A = k\frac{Q}{\ell^2} \;\rightarrow\; E_{Ax} = 0\,,\; E_{Ax} = -k\frac{Q}{\ell^2}$$

$$E_B = k\frac{Q}{\ell^2} \;\rightarrow\; E_{Bx} = -k\frac{Q}{\ell^2}\cos 30^\circ = -k\frac{\sqrt{3}Q}{2\ell^2},$$

$$E_{By} = -k\frac{Q}{\ell^2}\sin 30^\circ = -k\frac{Q}{2\ell^2}$$

$$E_x = E_{Ax} + E_{Bx} = -k\frac{\sqrt{3}Q}{2\ell^2} \qquad E_y = E_{Ay} + E_{By} = -k\frac{3Q}{2\ell^2}$$

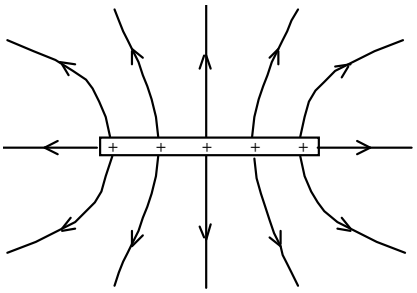
$$E = \sqrt{E_x^2 + E_y^2} = \sqrt{\frac{3k^2Q^2}{4\ell^4} + \frac{9k^2Q^2}{4\ell^4}} = \sqrt{\frac{12k^2Q^2}{4\ell^4}} = \boxed{\frac{\sqrt{3}kQ}{\ell^2}}$$

$$\theta = \tan^{-1}\frac{E_y}{E_x} = \tan^{-1}\frac{-k\frac{3Q}{2\ell^2}}{-k\frac{\sqrt{3}Q}{2\ell^2}} = \tan^{-1}\frac{-3}{-\sqrt{3}} = \tan^{-1}\sqrt{3} = \boxed{240^\circ}$$

(*b*) Now reverse the direction of $\vec{\mathbf{E}}_A$

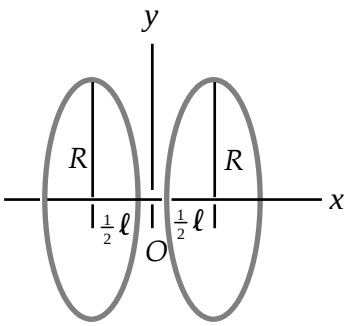
$$E_A = k\frac{Q}{\ell^2} \;\rightarrow\; E_{Ax} = 0\,,\; E_{Ax} = -k\frac{Q}{\ell^2}$$

$$E_B = k\frac{Q}{\ell^2} \;\rightarrow\; E_{Bx} = k\frac{Q}{\ell^2}\cos 30^\circ = k\frac{\sqrt{3}Q}{2\ell^2}\,,\; E_{By} = k\frac{Q}{\ell^2}\sin 30^\circ = k\frac{Q}{2\ell^2}$$



$$E_x = E_{Ax} + E_{Bx} = k\frac{\sqrt{3}Q}{2\ell^2} \qquad E_y = E_{Ay} + E_{By} = -k\frac{Q}{2\ell^2}$$

$$E = \sqrt{E_x^2 + E_y^2} = \sqrt{\frac{3k^2Q^2}{4\ell^4} + \frac{k^2Q^2}{4\ell^4}} = \sqrt{\frac{4k^2Q^2}{4\ell^4}} = \boxed{\frac{kQ}{\ell^2}}$$



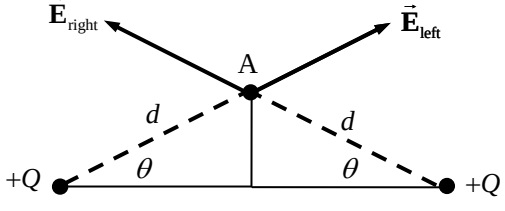
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\theta = \tan^{-1}\frac{E_y}{E_x} = \tan^{-1}\frac{k\dfrac{Q}{2\ell^2}}{-k\dfrac{\sqrt{3}Q}{2\ell^2}} = \tan^{-1}\frac{1}{-\sqrt{3}} = \boxed{330^\circ}$$

39. Near the plate, the lines should come from it almost vertically, because it is almost like an infinite line of charge when the observation point is close. When the observation point is far away, it will look like a point charge.

40. Consider Example 21-9. We use the result from this example, but shift the center of the ring to be at $x = \frac{1}{2}\ell$ for the ring on the right, and at $x = -\frac{1}{2}\ell$ for the ring on the left. The fact that the original expression has a factor of *x* results in the interpretation that the sign of the field expression will give the direction of the field. No special consideration needs to be given to the location of the point at which the field is to be calculated.

$$\vec{\mathbf{E}} = \vec{\mathbf{E}}_{\text{right}} + \vec{\mathbf{E}}_{\text{left}}$$



$$= \frac{1}{4\pi\varepsilon_0}\frac{Q\left(x-\frac{1}{2}\ell\right)}{\left[\left(x-\frac{1}{2}\ell\right)^2+R^2\right]^{3/2}}\hat{\mathbf{i}} + \frac{1}{4\pi\varepsilon_0}\frac{Q\left(x+\frac{1}{2}\ell\right)}{\left[\left(x+\frac{1}{2}\ell\right)^2+R^2\right]^{3/2}}\hat{\mathbf{i}}$$

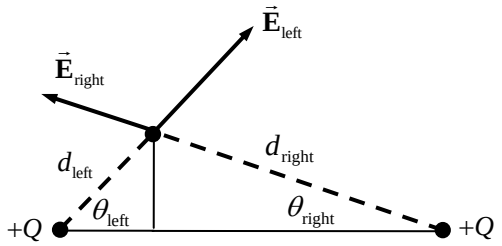
$$= \hat{\mathbf{i}}\frac{Q}{4\pi\varepsilon_0}\left\{\frac{\left(x-\frac{1}{2}\ell\right)}{\left[\left(x-\frac{1}{2}\ell\right)^2+R^2\right]^{3/2}} + \frac{\left(x+\frac{1}{2}\ell\right)}{\left[\left(x+\frac{1}{2}\ell\right)^2+R^2\right]^{3/2}}\right\}$$

41. Both charges must be of the same sign so that the electric fields created by the two charges oppose each other, and so can add to zero. The magnitudes of the two electric fields must be equal.

$$E_1 = E_2 \;\rightarrow\; k\frac{Q_1}{(\ell/3)^2} = k\frac{Q_2}{(2\ell/3)^2} \;\rightarrow\; 9Q_1 = \frac{9Q_2}{4} \;\rightarrow\; \frac{Q_1}{Q_2} = \boxed{\frac{1}{4}}$$

42. In each case, find the vector sum of the field caused by the charge on the left $\left(\vec{\mathbf{E}}_{\text{left}}\right)$ and the field caused by the charge on the right $\left(\vec{\mathbf{E}}_{\text{right}}\right)$

Point A: From the symmetry of the geometry, in calculating the electric field at point A only the vertical components of the fields need to be considered. The horizontal components will cancel each other.



$$\theta = \tan^{-1}\frac{5.0}{10.0} = 26.6^\circ$$

$$d = \sqrt{(5.0\,\text{cm})^2 + (10.0\,\text{cm})^2} = 0.1118\,\text{m}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E_{\text{A}} = 2\frac{kQ}{d^2}\sin\theta = 2\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{5.7\times10^{-6}\,\text{C}}{\left(0.1118\,\text{m}\right)^2}\sin 26.6^\circ = \boxed{3.7\times10^6\ \text{N/C}} \qquad \theta_{\text{A}} = \boxed{90^\circ}$$

Point B: Now the point is not symmetrically placed, and so horizontal and vertical components of each individual field need to be calculated to find the resultant electric field.

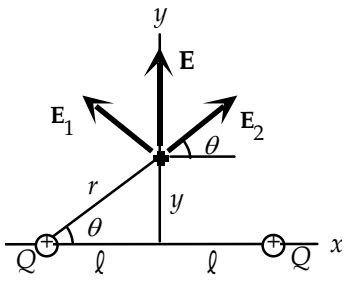
$$\theta_{\text{left}} = \tan^{-1}\frac{5.0}{5.0} = 45^\circ \qquad \theta_{\text{right}} = \tan^{-1}\frac{5.0}{15.0} = 18.4^\circ$$

$$d_{\text{left}} = \sqrt{\left(5.0\,\text{cm}\right)^2 + \left(5.0\,\text{cm}\right)^2} = 0.0707\,\text{m}$$

$$d_{\text{right}} = \sqrt{\left(5.0\,\text{cm}\right)^2 + \left(15.0\,\text{cm}\right)^2} = 0.1581\,\text{m}$$

$$E_x = \left(\vec{\mathbf{E}}_{\text{left}}\right)_x + \left(\vec{\mathbf{E}}_{\text{right}}\right)_x = k\frac{Q}{d_{\text{left}}^2}\cos\theta_{\text{left}} - k\frac{Q}{d_{\text{right}}^2}\cos\theta_{\text{right}}$$

$$= \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(5.7\times10^{-6}\,\text{C}\right)\left[\frac{\cos 45^\circ}{\left(0.0707\,\text{m}\right)^2} - \frac{\cos 18.4^\circ}{\left(0.1581\,\text{m}\right)^2}\right] = 5.30\times10^6\ \text{N/C}$$



$$E_y = \left(\vec{\mathbf{E}}_{\text{left}}\right)_y + \left(\vec{\mathbf{E}}_{\text{right}}\right)_y = k\frac{Q}{d_{\text{left}}^2}\sin\theta_{\text{left}} + k\frac{Q}{d_{\text{right}}^2}\sin\theta_{\text{right}}$$

$$= \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(5.7\times10^{-6}\,\text{C}\right)\left[\frac{\sin 45^\circ}{\left(0.0707\,\text{m}\right)^2} + \frac{\sin 18.4^\circ}{\left(0.1581\,\text{m}\right)^2}\right] = 7.89\times10^6\ \text{N/C}$$

$$E_{\text{B}} = \sqrt{E_x^2 + E_y^2} = \boxed{9.5\times10^6\ \text{N/C}} \qquad \theta_B = \tan^{-1}\frac{E_y}{E_x} = \boxed{56^\circ}$$

The results are consistent with Figure 21-34b. In the figure, the field at Point A points straight up, matching the calculations. The field at Point B should be to the right and vertical, matching the calculations. Finally, the field lines are closer together at Point B than at Point A, indicating that the field is stronger there, matching the calculations.

43. (*a*) See the diagram. From the symmetry of the charges, we see that the net electric field points along the *y* axis.

$$\vec{\mathbf{E}} = 2\frac{Q}{4\pi\varepsilon_0\left(\ell^2 + y^2\right)}\sin\theta\,\hat{\mathbf{j}} = \boxed{\frac{Qy}{2\pi\varepsilon_0\left(\ell^2 + y^2\right)^{3/2}}\hat{\mathbf{j}}}$$

(*b*) To find the position where the magnitude is a maximum, set the first derivative with respect to *y* equal to 0, and solve for the *y* value.

$$E = \frac{Qy}{2\pi\varepsilon_0\left(\ell^2 + y^2\right)^{3/2}} \quad \rightarrow$$

$$\frac{dE}{dy} = \frac{Q}{2\pi\varepsilon_0\left(\ell^2 + y^2\right)^{3/2}} + \left(-\tfrac{3}{2}\right)\frac{Qy}{2\pi\varepsilon_0\left(\ell^2 + y^2\right)^{5/2}}\left(2y\right) = 0 \quad \rightarrow$$

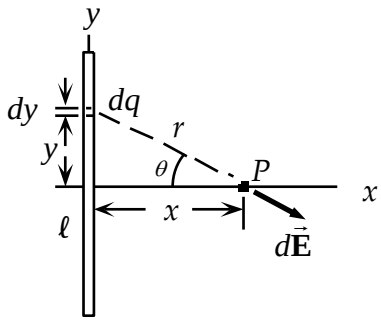
$$\frac{1}{\left(\ell^2 + y^2\right)^{3/2}} = \frac{3y^2}{\left(\ell^2 + y^2\right)^{5/2}} \quad \rightarrow \quad y^2 = \tfrac{1}{2}\ell^2 \quad \rightarrow \quad y = \boxed{\pm\ell/\sqrt{2}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

This has to be a maximum, because the magnitude is positive, the field is 0 midway between the charges, and $E \to 0$ as $y \to \infty$.

44. From Example 21-9, the electric field along the *x*-axis is $E = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Qx}{\left(x^2+a^2\right)^{\frac{3}{2}}}$. To find the position where the magnitude is a maximum, we differentiate and set the first derivative equal to zero.

$$\frac{dE}{dx} = \frac{Q}{4\pi\varepsilon_0}\frac{\left(x^2+a^2\right)^{\frac{3}{2}} - x\frac{3}{2}\left(x^2+a^2\right)^{\frac{1}{2}}2x}{\left(x^2+a^2\right)^3} = \frac{Q}{4\pi\varepsilon_0\left(x^2+a^2\right)^{\frac{5}{2}}}\left[\left(x^2+a^2\right)-3x^2\right]$$



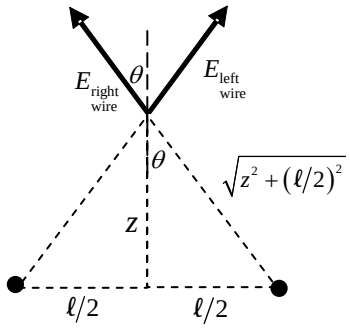
$$= \frac{Q}{4\pi\varepsilon_0\left(x^2+a^2\right)^{\frac{5}{2}}}\left[a^2-2x^2\right] = 0 \quad \rightarrow \quad \boxed{x_M = \pm\frac{a}{\sqrt{2}}}$$

Note that $E = 0$ at $x = 0$ and $x = \infty$, and that $|E| > 0$ for $0 < |x| < \infty$. Thus the value of the magnitude of *E* at $x = x_M$ must be a maximum. We could also show that the value is a maximum by using the second derivative test.

45. Because the distance from the wire is much smaller than the length of the wire, we can approximate the electric field by the field of an infinite wire, which is derived in Example 21-11.

$$E = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{x} = \frac{1}{4\pi\varepsilon_0}\frac{2\lambda}{x} = \left(8.988\times10^9\ \frac{\text{N}\bullet\text{m}^2}{\text{C}^2}\right)\frac{2\left(\dfrac{4.75\times10^{-6}\,\text{C}}{2.0\,\text{m}}\right)}{\left(2.4\times10^{-2}\,\text{m}\right)} = \boxed{\begin{array}{l}1.8\times10^6\ \text{N/C},\\ \text{away from the wire}\end{array}}$$

46. This is essentially Example 21-11 again, but with different limits of integration. From the diagram here, we see that the maximum angle is given by $\sin\theta = \dfrac{\ell/2}{\sqrt{x^2+(\ell/2)^2}}$. We evaluate the results at that angle.



$$E = \frac{\lambda}{4\pi\varepsilon_0 x}\left(\sin\theta\right)\Bigg|_{\sin\theta=\frac{-\ell/2}{\sqrt{x^2+(\ell/2)^2}}}^{\sin\theta=\frac{\ell/2}{\sqrt{x^2+(\ell/2)^2}}}$$

$$= \frac{\lambda}{4\pi\varepsilon_0 x}\left[\frac{\ell/2}{\sqrt{x^2+(\ell/2)^2}} - \left(-\frac{\ell/2}{\sqrt{x^2+(\ell/2)^2}}\right)\right] = \frac{\lambda\ell}{4\pi\varepsilon_0 x\sqrt{x^2+(\ell/2)^2}} = \boxed{\frac{\lambda}{2\pi\varepsilon_0}\frac{\ell}{x\left(4x^2+\ell^2\right)^{1/2}}}$$

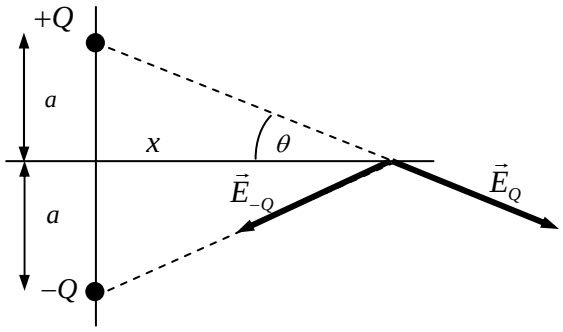
47. If we consider just one wire, then from the answer to problem 46, we would have the following. Note that the distance from the wire to the point in question is $x = \sqrt{z^2+(\ell/2)^2}$.

$$E_{\text{wire}} = \frac{\lambda}{2\pi\varepsilon_0}\frac{\ell}{\sqrt{z^2+(\ell/2)^2}\left(4\left[z^2+(\ell/2)^2\right]+\ell^2\right)^{1/2}}$$

But the total field is not simply four times the above expression, because the fields due to the four wires are not parallel to each other.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Consider a side view of the problem. The two dots represent two parallel wires, on opposite sides of the square. Note that only the vertical component of the field due to each wire will actually contribute to the total field. The horizontal components will cancel.



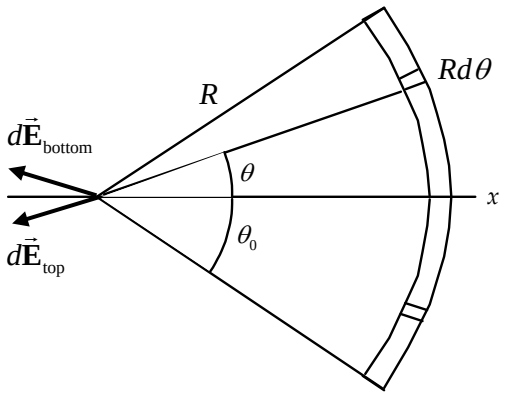
$$E_{\text{wire}} = 4\left(E_{\text{wire}}\right)\cos\theta = 4\left(E_{\text{wire}}\right)\frac{z}{\sqrt{z^2+\left(\ell/2\right)^2}}$$

$$E_{\text{wire}} = 4\left[\frac{\lambda}{2\pi\varepsilon_0}\frac{\ell}{\sqrt{z^2+\left(\ell/2\right)^2}\left(4\left[z^2+\left(\ell/2\right)^2\right]+\ell^2\right)^{1/2}}\right]\frac{z}{\sqrt{z^2+\left(\ell/2\right)^2}}$$

$$= \boxed{\frac{8\lambda\ell z}{\pi\varepsilon_0\left(4z^2+\ell^2\right)\left(4z^2+2\ell^2\right)^{1/2}}}$$

The direction is vertical, perpendicular to the loop.

48. From the diagram, we see that the *x* components of the two fields will cancel each other at the point P. Thus the net electric field will be in the negative *y*-direction, and will be twice the *y*-component of either electric field vector.

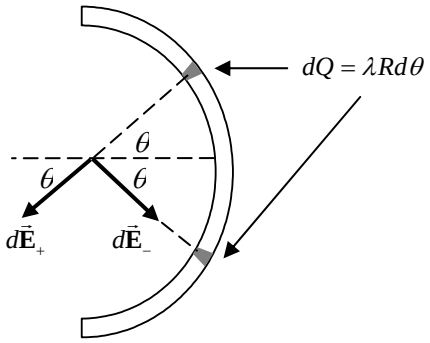


$$E_{\text{net}} = 2E\sin\theta = 2\frac{kQ}{x^2+a^2}\sin\theta$$

$$= \frac{2kQ}{x^2+a^2}\frac{a}{\left(x^2+a^2\right)^{1/2}}$$

$$= \boxed{\frac{2kQa}{\left(x^2+a^2\right)^{3/2}} \text{ in the negative } y \text{ direction}}$$

49. Select a differential element of the arc which makes an angle of θ with the *x* axis. The length of this element is $Rd\theta$, and the charge on that element is $dq = \lambda Rd\theta$. The magnitude of the field produced by that element is $dE = \frac{1}{4\pi\varepsilon_0}\frac{\lambda Rd\theta}{R^2}$. From the diagram, considering pieces of the arc that are symmetric with respect to the *x* axis, we see that the total field will only have an *x* component. The vertical components of the field due to symmetric portions of the arc will cancel each other. So we have the following.



$$dE_{\text{horizontal}} = \frac{1}{4\pi\varepsilon_0}\frac{\lambda Rd\theta}{R^2}\cos\theta$$

$$E_{\text{horizontal}} = \int_{-\theta_0}^{\theta_0}\frac{1}{4\pi\varepsilon_0}\cos\theta\frac{\lambda Rd\theta}{R^2} = \frac{\lambda}{4\pi\varepsilon_0 R}\int_{-\theta_0}^{\theta_0}\cos\theta d\theta = \frac{\lambda}{4\pi\varepsilon_0 R}\left[\sin\theta_0-\sin\left(-\theta_0\right)\right] = \frac{2\lambda\sin\theta_0}{4\pi\varepsilon_0 R}$$

The field points in the negative *x* direction, so $E = \boxed{-\frac{2\lambda\sin\theta_0}{4\pi\varepsilon_0 R}\hat{\mathbf{i}}}$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

50. (*a*) Select a differential element of the arc which makes an angle of θ with the *x* axis. The length of this element is $Rd\theta$, and the charge on that element is $dq = \lambda R d\theta$. The magnitude of the field produced by that element is $dE = \dfrac{1}{4\pi\varepsilon_0}\dfrac{\lambda R d\theta}{R^2}$. From the diagram, considering pieces of the arc that are symmetric with respect to the *x* axis, we see that the total field will only have a *y* component, because the magnitudes of the fields due to those two pieces are the same. From the diagram we see that the field will point down. The horizontal components of the field cancel.

$$dE_{\text{vertical}} = \frac{1}{4\pi\varepsilon_0}\frac{\lambda R d\theta}{R^2}\sin\theta = \frac{\lambda_0}{4\pi\varepsilon_0 R}\sin^2\theta d\theta$$

$$E_{\text{vertical}} = \int_{-\pi/2}^{\pi/2}\frac{\lambda_0}{4\pi\varepsilon_0 R}\sin^2\theta d\theta = \frac{\lambda_0}{4\pi\varepsilon_0 R}\int_{-\pi/2}^{\pi/2}\sin^2\theta d\theta = \frac{\lambda_0}{4\pi\varepsilon_0 R}\left(\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right)_{-\pi/2}^{\pi/2}$$

$$= \frac{\lambda_0}{4\pi\varepsilon_0 R}\left(\tfrac{1}{2}\pi\right) = \frac{\lambda_0}{8\varepsilon_0 R} \quad \rightarrow \quad \vec{\mathbf{E}} = \boxed{-\frac{\lambda_0}{8\varepsilon_0 R}\hat{\mathbf{j}}}$$

(*b*) The force on the electron is given by Eq. 21-3. The acceleration is found from the force.

$$\vec{\mathbf{F}} = m\vec{\mathbf{a}} = q\vec{\mathbf{E}} = -\frac{q\lambda_0}{8\varepsilon_0 R}\hat{\mathbf{j}} \quad \rightarrow$$

$$\vec{\mathbf{a}} = -\frac{q\lambda_0}{8m\varepsilon_0 R}\hat{\mathbf{j}} = \frac{e\lambda_0}{8m\varepsilon_0 R}\hat{\mathbf{j}} = \frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(1.0\times10^{-6}\,\text{C/m}\right)}{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(0.010\,\text{m}\right)}\hat{\mathbf{j}}$$

$$= \boxed{2.5\times10^{17}\,\text{m/s}^2\,\hat{\mathbf{j}}}$$

51. (*a*) If we follow the first steps of Example 21-11, and refer to Figure 21-29, then the differential electric field due to the segment of wire is still $dE = \dfrac{1}{4\pi\varepsilon_0}\dfrac{\lambda\, dy}{\left(x^2+y^2\right)}$. But now there is no symmetry, and so we calculate both components of the field.

$$dE_x = dE\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{\lambda\, dy}{\left(x^2+y^2\right)}\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{\lambda x\, dy}{\left(x^2+y^2\right)^{3/2}}$$

$$dE_y = -dE\sin\theta = -\frac{1}{4\pi\varepsilon_0}\frac{\lambda\, dy}{\left(x^2+y^2\right)}\sin\theta = -\frac{1}{4\pi\varepsilon_0}\frac{\lambda y\, dy}{\left(x^2+y^2\right)^{3/2}}$$

The anti-derivatives needed are in Appendix B4.

$$E_x = \int_0^{\ell}\frac{1}{4\pi\varepsilon_0}\frac{\lambda x\, dy}{\left(x^2+y^2\right)^{3/2}} = \frac{\lambda x}{4\pi\varepsilon_0}\int_0^{\ell}\frac{dy}{\left(x^2+y^2\right)^{3/2}} = \frac{\lambda x}{4\pi\varepsilon_0}\left(\frac{y}{x^2\sqrt{x^2+y^2}}\right)_0^{\ell}$$

$$= \boxed{\frac{\lambda\ell}{4\pi\varepsilon_0 x\sqrt{x^2+\ell^2}}}$$

$$E_y = -\int_0^{\ell} \frac{1}{4\pi\varepsilon_0}\frac{\lambda y\,dy}{\left(x^2+y^2\right)^{3/2}} = -\frac{\lambda}{4\pi\varepsilon_0}\int_0^{\ell}\frac{y\,dy}{\left(x^2+y^2\right)^{3/2}} = -\frac{\lambda}{4\pi\varepsilon_0}\left(\frac{-1}{\sqrt{x^2+y^2}}\right)_0^{\ell}$$

$$= \frac{\lambda}{4\pi\varepsilon_0}\left(\frac{1}{\sqrt{x^2+\ell^2}} - \frac{1}{x}\right) = \boxed{\frac{\lambda}{4\pi\varepsilon_0 x\sqrt{x^2+\ell^2}}\left(x-\sqrt{x^2+\ell^2}\right)}$$

Note that $E_y < 0$, and so the electric field points to the right and down.

(*b*) The angle that the electric field makes with the *x* axis is given as follows.

$$\tan\theta = \frac{E_y}{E_x} = \frac{\dfrac{\lambda}{4\pi\varepsilon_0 x\sqrt{x^2+\ell^2}}\left(x-\sqrt{x^2+\ell^2}\right)}{\dfrac{\lambda\ell}{4\pi\varepsilon_0 x\sqrt{x^2+\ell^2}}} = \frac{x-\sqrt{x^2+\ell^2}}{\ell} = \frac{x}{\ell} - \sqrt{1+\frac{x^2}{\ell^2}}$$

As $\ell \to \infty$, the expression becomes $\tan\theta = -1$, and so the field makes an angle of $\boxed{45°\text{ below the } x \text{ axis}}$.

52. Please note: the first printing of the textbook gave the length of the charged wire as 6.00 m, but it should have been 6.50 m. That error has been corrected in later printings, and the following solution uses a length of 6.50 m.

(*a*) If we follow the first steps of Example 21-11, and refer to Figure 21-29, then the differential electric field due to the segment of wire is still $dE = \dfrac{1}{4\pi\varepsilon_0}\dfrac{\lambda\,dy}{\left(x^2+y^2\right)}$. But now there is no symmetry, and so we calculate both components of the field.

$$dE_x = dE\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{\lambda\,dy}{\left(x^2+y^2\right)}\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{\lambda x\,dy}{\left(x^2+y^2\right)^{3/2}}$$

$$dE_y = -dE\cos\theta = -\frac{1}{4\pi\varepsilon_0}\frac{\lambda\,dy}{\left(x^2+y^2\right)}\sin\theta = -\frac{1}{4\pi\varepsilon_0}\frac{\lambda y\,dy}{\left(x^2+y^2\right)^{3/2}}$$

The anti-derivatives needed are in Appendix B4.

$$E_x = \int_{y_{\min}}^{y_{\max}} \frac{1}{4\pi\varepsilon_0}\frac{\lambda x\,dy}{\left(x^2+y^2\right)^{3/2}} = \frac{\lambda x}{4\pi\varepsilon_0}\int_{y_{\min}}^{y_{\max}}\frac{dy}{\left(x^2+y^2\right)^{3/2}} = \frac{\lambda x}{4\pi\varepsilon_0}\left(\frac{y}{x^2\sqrt{x^2+y^2}}\right)_{y_{\min}}^{y_{\max}}$$

$$= \frac{\lambda}{4\pi\varepsilon_0 x}\left(\frac{y_{\max}}{\sqrt{x^2+y_{\max}^2}} - \frac{y_{\min}}{\sqrt{x^2+y_{\min}^2}}\right)$$

$$= \left(8.99\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\frac{\left(3.15\times10^{-6}\,\text{C}\right)/\left(6.50\,\text{m}\right)}{\left(0.250\,\text{m}\right)}$$

$$\left(\frac{2.50\,\text{m}}{\sqrt{\left(0.250\,\text{m}\right)^2+\left(2.50\,\text{m}\right)^2}} - \frac{\left(-4.00\,\text{m}\right)}{\sqrt{\left(0.250\,\text{m}\right)^2+\left(-4.00\,\text{m}\right)^2}}\right)$$

$$= 3.473\times10^4\ \text{N/C} \approx \boxed{3.5\times10^4\ \text{N/C}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E_y = -\int_{y_{\min}}^{y_{\max}} \frac{1}{4\pi\varepsilon_0}\frac{\lambda y\,dy}{\left(x^2+y^2\right)^{3/2}} = -\frac{\lambda}{4\pi\varepsilon_0}\int_{y_{\min}}^{y_{\max}} \frac{y\,dy}{\left(x^2+y^2\right)^{3/2}} = -\frac{\lambda}{4\pi\varepsilon_0}\left(\frac{-1}{\sqrt{x^2+y^2}}\right)_{y_{\min}}^{y_{\max}}$$

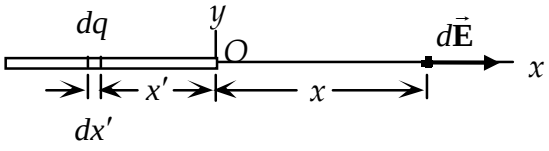
$$= \frac{\lambda}{4\pi\varepsilon_0}\left(\frac{1}{\sqrt{x^2+y_{\max}^2}} - \frac{1}{\sqrt{x^2+y_{\min}^2}}\right)$$

$$= \left(8.99\times10^9\ \frac{\text{N}\bullet\text{m}^2}{\text{C}^2}\right)\frac{\left(3.15\times10^{-6}\text{C}\right)}{\left(6.50\,\text{m}\right)}$$

$$\left(\frac{1}{\sqrt{\left(0.250\,\text{m}\right)^2+\left(2.50\,\text{m}\right)^2}} - \frac{1}{\sqrt{\left(0.250\,\text{m}\right)^2+\left(-4.00\,\text{m}\right)^2}}\right)$$

$$= 647\ \text{N/C} \approx \boxed{650\ \text{N/C}}$$

(*b*) We calculate the infinite line of charge result, and calculate the errors.



$$E = \frac{\lambda}{2\pi\varepsilon_0 x} = \frac{2\lambda}{4\pi\varepsilon_0 x} = 2\left(8.99\times10^9\ \frac{\text{N}\bullet\text{m}^2}{\text{C}^2}\right)\frac{\left(3.15\times10^{-6}\text{C}\right)}{\left(6.50\,\text{m}\right)\left(0.250\,\text{m}\right)} = 3.485\times10^4\ \text{N/m}$$

$$\frac{E_x - E}{E} = \frac{\left(3.473\times10^4\ \text{N/C}\right)-\left(3.485\times10^4\ \text{N/m}\right)}{\left(3.485\times10^4\ \text{N/m}\right)} = \boxed{-0.0034}$$

$$\frac{E_y}{E} = \frac{\left(647\ \text{N/C}\right)}{\left(3.485\times10^4\ \text{N/m}\right)} = \boxed{0.019}$$

And so we see that E_x is only about 0.3% away from the value obtained from the infinite line of charge, and E_y is only about 2% of the value obtained from the infinite line of charge. The field of an infinite line of charge result would be a good approximation for the field due to this wire segment.

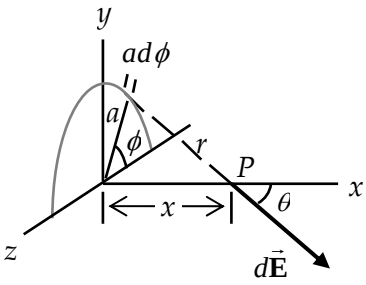
53. Choose a differential element of the rod dx' a distance x' from the origin, as shown in the diagram. The charge on that differential element is $dq = \frac{Q}{\ell}dx'$. The variable x' is treated as positive,

so that the field due to this differential element is $dE = \frac{1}{4\pi\varepsilon_0}\frac{dq}{\left(x+x'\right)^2} = \frac{Q}{4\pi\varepsilon_0\ell}\frac{dx'}{\left(x+x'\right)^2}$. Integrate along the rod to find the total field.

$$E = \int dE = \int_0^{\ell} \frac{Q}{4\pi\varepsilon_0\ell}\frac{dx'}{\left(x+x'\right)^2} = \frac{Q}{4\pi\varepsilon_0\ell}\int_0^{\ell}\frac{dx'}{\left(x+x'\right)^2} = \frac{Q}{4\pi\varepsilon_0\ell}\left(-\frac{1}{x+x'}\right)_0^{\ell} = \frac{Q}{4\pi\varepsilon_0\ell}\left(\frac{1}{x}-\frac{1}{x+\ell}\right)$$

$$= \boxed{\frac{Q}{4\pi\varepsilon_0 x\left(x+\ell\right)}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



54. As suggested, we divide the plane into long narrow strips of width dy and length ℓ. The charge on the strip is the area of the strip times the charge per unit area: $dq = \sigma \ell dy$. The charge per unit length on the strip is $\lambda = \dfrac{dq}{\ell} = \sigma dy$. From Example 21-11, the field due to that narrow strip is $dE = \dfrac{\lambda}{2\pi\varepsilon_0\sqrt{y^2+z^2}} = \dfrac{\sigma dy}{2\pi\varepsilon_0\sqrt{y^2+z^2}}$. From Figure 21-68 in the textbook, we see that this field does not point vertically. From the symmetry of the plate, there is another long narrow strip a distance y on the other side of the origin, which would create the same magnitude electric field. The horizontal components of those two fields would cancel each other, and so we only need calculate the vertical component of the field. Then we integrate along the y direction to find the total field.

$$dE = \frac{\sigma dy}{2\pi\varepsilon_0\sqrt{y^2+z^2}} \;;\; dE_z = dE\cos\theta = \frac{\sigma z dy}{2\pi\varepsilon_0\left(y^2+z^2\right)}$$

$$E = E_z = \int_{-\infty}^{\infty}\frac{\sigma z dy}{2\pi\varepsilon_0\left(y^2+z^2\right)} = \frac{\sigma z}{2\pi\varepsilon_0}\int_{-\infty}^{\infty}\frac{dy}{\left(y^2+z^2\right)} = \frac{\sigma z}{2\pi\varepsilon_0}\frac{1}{z}\left(\tan^{-1}\frac{y}{z}\right)_{-\infty}^{\infty}$$

$$= \frac{\sigma}{2\pi\varepsilon_0}\left[\tan^{-1}(\infty) - \tan^{-1}(-\infty)\right] = \frac{\sigma}{2\pi\varepsilon_0}\left[\frac{\pi}{2} - \left(-\frac{\pi}{2}\right)\right] = \boxed{\frac{\sigma}{2\varepsilon_0}}$$

55. Take Figure 21-28 and add the angle ϕ, measured from the –z axis, as indicated in the diagram. Consider an infinitesimal length of the ring $ad\phi$. The charge on that infinitesimal length is $dq = \lambda(ad\phi) = \dfrac{Q}{\pi a}(ad\phi) = \dfrac{Q}{\pi}d\phi$. The charge creates an infinitesimal electric field, $d\vec{\mathbf{E}}$, with magnitude $dE = \dfrac{1}{4\pi\varepsilon_0}\dfrac{dq}{r^2} = \dfrac{1}{4\pi\varepsilon_0}\dfrac{\frac{Q}{\pi}d\phi}{x^2+a^2}$. From the symmetry of the figure, we see that the z component of $d\vec{\mathbf{E}}$ will be cancelled by the z component due to the piece of the ring that is on the opposite side of the y axis. The trigonometric relationships give $dE_x = dE\cos\theta$ and $dE_y = -dE\sin\theta\sin\phi$. The factor of $\sin\phi$ can be justified by noting that $dE_y = 0$ when $\phi = 0$, and $dE_y = -dE\sin\theta$ when $\phi = \pi/2$.

$$dE_x = dE\cos\theta = \frac{Q}{4\pi^2\varepsilon_0}\frac{d\phi}{x^2+a^2}\frac{x}{\sqrt{x^2+a^2}} = \frac{Qx}{4\pi^2\varepsilon_0}\frac{d\phi}{\left(x^2+a^2\right)^{3/2}}$$

$$E_x = \frac{Qx}{4\pi^2\varepsilon_0\left(x^2+a^2\right)^{3/2}}\int_0^{\pi}d\phi = \boxed{\frac{Qx}{4\pi\varepsilon_0\left(x^2+a^2\right)^{3/2}}}$$

$$dE_y = -dE\sin\theta\sin\phi = -\frac{Q}{4\pi^2\varepsilon_0}\frac{d\phi}{x^2+a^2}\frac{a}{\sqrt{x^2+a^2}}\sin\phi = -\frac{Qa}{4\pi^2\varepsilon_0\left(x^2+a^2\right)^{3/2}}\sin\phi d\phi$$

$$E_y = -\frac{Qa}{4\pi^2\varepsilon_0\left(x^2+a^2\right)^{3/2}}\int_0^{\pi}\sin\phi d\phi = -\frac{Qa}{4\pi^2\varepsilon_0\left(x^2+a^2\right)^{3/2}}\left[(-\cos\pi) - (-\cos 0)\right]$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \boxed{-\frac{2Qa}{4\pi^2\varepsilon_0\left(x^2+a^2\right)^{3/2}}}$$

We can write the electric field in vector notation.

$$\vec{\mathbf{E}} = \frac{Qx}{4\pi\varepsilon_0\left(x^2+a^2\right)^{3/2}}\hat{\mathbf{i}} - \frac{2Qa}{4\pi^2\varepsilon_0\left(x^2+a^2\right)^{3/2}}\hat{\mathbf{j}} = \boxed{\frac{Q}{4\pi\varepsilon_0\left(x^2+a^2\right)^{3/2}}\left(x\hat{\mathbf{i}} - \frac{2a}{\pi}\hat{\mathbf{j}}\right)}$$

56. (*a*) Since the field is uniform, the electron will experience a constant force in the direction opposite to its velocity, so the acceleration is constant and negative. Use constant acceleration relationships with a final velocity of 0.

$$F = ma = qE = -eE \;\rightarrow\; a = -\frac{eE}{m} \;;\; v^2 = v_0^2 + 2a\Delta x = 0 \;\rightarrow$$

$$\Delta x = -\frac{v_0^2}{2a} = -\frac{v_0^2}{2\left(-\frac{eE}{m}\right)} = \frac{mv_0^2}{2eE} = \frac{\left(9.11\times10^{-31}\text{kg}\right)\left(27.5\times10^6\text{ m/s}\right)^2}{2\left(1.60\times10^{-19}\text{C}\right)\left(11.4\times10^3\text{ N/C}\right)} = \boxed{0.189\text{ m}}$$

(*b*) Find the elapsed time from constant acceleration relationships. Upon returning to the original position, the final velocity will be the opposite of the initial velocity.

$$v = v_0 + at \;\rightarrow$$

$$t = \frac{v - v_0}{a} = \frac{-2v_0}{\left(-\frac{eE}{m}\right)} = \frac{2mv_0}{eE} = \frac{2\left(9.11\times10^{-31}\text{kg}\right)\left(27.5\times10^6\text{ m/s}\right)}{\left(1.60\times10^{-19}\text{C}\right)\left(11.4\times10^3\text{ N/C}\right)} = \boxed{2.75\times10^{-8}\text{s}}$$

57. (*a*) The acceleration is produced by the electric force.

$$\vec{\mathbf{F}}_{\text{net}} = m\vec{\mathbf{a}} = q\vec{\mathbf{E}} = -e\vec{\mathbf{E}} \;\rightarrow$$

$$\vec{\mathbf{a}} = -\frac{e}{m}\vec{\mathbf{E}} = -\frac{\left(1.60\times10^{-19}\text{C}\right)}{\left(9.11\times10^{-31}\text{kg}\right)}\left[\left(2.0\hat{\mathbf{i}} + 8.0\hat{\mathbf{j}}\right)\times10^4\text{ N/C}\right] = \left(-3.513\times10^{15}\hat{\mathbf{i}} - 1.405\times10^{16}\hat{\mathbf{j}}\right)\text{m/s}^2$$

$$\approx \boxed{-3.5\times10^{15}\text{ m/s}^2\,\hat{\mathbf{i}} - 1.4\times10^{16}\text{ m/s}^2\,\hat{\mathbf{j}}}$$

(*b*) The direction is found from the components of the velocity.

$$\vec{\mathbf{v}} = \vec{\mathbf{v}} + \vec{\mathbf{a}}t = \left(8.0\times10^4\text{ m/s}\right)\hat{\mathbf{j}} + \left[\left(-3.513\times10^{15}\hat{\mathbf{i}} - 1.405\times10^{16}\hat{\mathbf{j}}\right)\text{m/s}^2\right]\left(1.0\times10^{-9}\text{s}\right)$$

$$= \left(-3.513\times10^6\hat{\mathbf{i}} - 1.397\times10^7\hat{\mathbf{j}}\right)\text{m/s}$$

$$\tan^{-1}\frac{v_y}{v_x} = \tan^{-1}\left(\frac{-1.397\times10^7\text{ m/s}}{-3.513\times10^6\text{ m/s}}\right) = 256^\circ \text{ or } -104^\circ$$

This is the direction relative to the *x* axis. The direction of motion relative to the initial direction is measured from the *y* axis, and so is $\boxed{\theta = 166^\circ \text{ counter-clockwise}}$ from the initial direction.

58. (*a*) The electron will experience a force in the opposite direction to the electric field. Since the electron is to be brought to rest, the electric field must be in the same direction as the initial velocity of the electron, and so is to the $\boxed{\text{right}}$.

(*b*) Since the field is uniform, the electron will experience a constant force, and therefore have a constant acceleration. Use constant acceleration relationships to find the field strength.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$F = qE = ma \;\rightarrow\; a = \frac{qE}{m} \qquad v^2 = v_0^2 + 2a\Delta x = v_0^2 + 2\frac{qE}{m}\Delta x \;\rightarrow$$

$$E = \frac{m\left(v^2 - v_0^2\right)}{2q\Delta x} = \frac{-mv_0^2}{2q\Delta x} = -\frac{\left(9.109\times10^{-31}\,\text{kg}\right)\left(7.5\times10^{5}\,\text{m/s}\right)^2}{2\left(-1.602\times10^{-19}\,\text{C}\right)\left(0.040\,\text{m}\right)} = \boxed{40\,\text{N/C}} \;\text{(2 sig. fig.)}$$

59. The angle is determined by the velocity. The *x* component of the velocity is constant. The time to pass through the plates can be found from the *x* motion. Then the *y* velocity can be found using constant acceleration relationships.

$$x = v_0 t \;\rightarrow\; t = \frac{x}{v_0} \;;\; v_y = v_{y0} + a_y t = -\frac{eE}{m}\frac{x}{v_0}$$

$$\tan\theta = \frac{v_y}{v_x} = \frac{-\frac{eE}{m}\frac{x}{v_0}}{v_0} = -\frac{eEx}{mv_0^2} = -\frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(5.0\times10^{3}\,\text{N/C}\right)\left(0.049\,\text{m}\right)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(1.00\times10^{7}\,\text{m/s}\right)^2} = -.4303 \;\rightarrow$$

$$\theta = \tan^{-1}\left(-0.4303\right) = \boxed{-23^\circ}$$

60. Since the field is constant, the force on the electron is constant, and so the acceleration is constant. Thus constant acceleration relationships can be used. The initial conditions are $x_0 = 0,\; y_0 = 0,$ $v_{x0} = 1.90\,\text{m/s},$ and $v_{y0} = 0.$

$$\vec{\mathbf{F}} = m\vec{\mathbf{a}} = q\vec{\mathbf{E}} \;\rightarrow\; \vec{\mathbf{a}} = \frac{q}{m}\vec{\mathbf{E}} = -\frac{e}{m}\vec{\mathbf{E}} \;;\; a_x = -\frac{e}{m}E_x \;,\; a_y = -\frac{e}{m}E_y$$

$$x = x_0 + v_{x0}t + \tfrac{1}{2}a_x t^2 = v_{x0}t - \frac{eE_x}{2m}t^2$$

$$= \left(1.90\,\text{m/s}\right)\left(2.0\,\text{s}\right) - \frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(2.00\times10^{-11}\,\text{N/C}\right)}{2\left(9.11\times10^{-31}\,\text{kg}\right)}\left(2.0\,\text{s}\right)^2 = \boxed{-3.2\,\text{m}}$$

$$y = y_0 + v_{y0}t + \tfrac{1}{2}a_y t^2 = -\frac{eE_y}{2m}t^2 = -\frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(-1.20\times10^{-11}\,\text{N/C}\right)}{2\left(9.11\times10^{-31}\,\text{kg}\right)}\left(2.0\,\text{s}\right)^2 = \boxed{4.2\,\text{m}}$$

61. (*a*) The field along the axis of the ring is given in Example 21-9, with the opposite sign because this ring is negatively charged. The force on the charge is the field times the charge *q*. Note that if *x* is positive, the force is to the left, and if *x* is negative, the force is to the right. Assume that $x \ll R$.

$$F = qE = \frac{q}{4\pi\varepsilon_0}\frac{\left(-Q\right)x}{\left(x^2 + R^2\right)^{3/2}} = \frac{-qQx}{4\pi\varepsilon_0}\frac{1}{\left(x^2 + R^2\right)^{3/2}} \approx \frac{-qQx}{4\pi\varepsilon_0 R^3}$$

This has the form of a simple harmonic oscillator, where the "spring constant" is $k_{\text{elastic}} = \dfrac{Qq}{4\pi\varepsilon_0 R^3}.$

(*b*) The spring constant can be used to find the period. See Eq. 14-7b.

$$T = 2\pi\sqrt{\frac{m}{k_{\text{elastic}}}} = 2\pi\sqrt{\frac{m}{\frac{Qq}{4\pi\varepsilon_0 R^3}}} = 2\pi\sqrt{\frac{m4\pi\varepsilon_0 R^3}{Qq}} = 4\pi\sqrt{\frac{m\pi\varepsilon_0 R^3}{Qq}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

62. (*a*) The dipole moment is given by the product of the positive charge and the separation distance.

$$p = Q\ell = \left(1.60\times10^{-19}\,\text{C}\right)\left(0.68\times10^{-9}\,\text{m}\right) = 1.088\times10^{-28}\,\text{C•m} \approx \boxed{1.1\times10^{-28}\,\text{C•m}}$$

(*b*) The torque on the dipole is given by Eq. 21-9a.

$$\tau = pE\sin\theta = \left(1.088\times10^{-28}\,\text{C•m}\right)\left(2.2\times10^{4}\ \text{N/C}\right)\left(\sin 90°\right) = \boxed{2.4\times10^{-24}\,\text{C•m}}$$

(*c*) $\tau = pE\sin\theta = \left(1.088\times10^{-28}\,\text{C•m}\right)\left(2.2\times10^{4}\ \text{N/C}\right)\left(\sin 45°\right) = \boxed{1.7\times10^{-24}\,\text{N•m}}$

(*d*) The work done by an external force is the change in potential energy. Use Eq. 21-10.

$$W = \Delta U = \left(-pE\cos\theta_{\text{final}}\right) - \left(-pE\cos\theta_{\text{initial}}\right) = pE\left(\cos\theta_{\text{initial}} - \cos\theta_{\text{final}}\right)$$

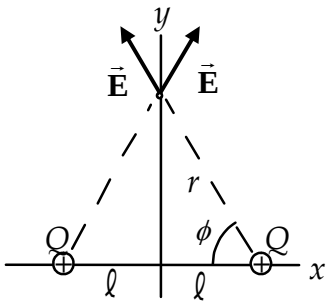
$$= \left(1.088\times10^{-28}\,\text{C•m}\right)\left(2.2\times10^{4}\ \text{N/C}\right)\left[1-(-1)\right] = \boxed{4.8\times10^{-24}\,\text{J}}$$

63. (*a*) The dipole moment is the effective charge of each atom times the separation distance.

$$p = Q\ell \ \rightarrow\ Q = \frac{p}{\ell} = \frac{3.4\times10^{-30}\,\text{C•m}}{1.0\times10^{-10}\,\text{m}} = \boxed{3.4\times10^{-20}\,\text{C}}$$

(*b*) $\dfrac{Q}{e} = \dfrac{3.4\times10^{-20}\,\text{C}}{1.60\times10^{-19}\,\text{C}} = 0.21$ No, the net charge on each atom is not an integer multiple of *e*. This is an indication that the H and Cl atoms are not ionized – they haven't fully gained or lost an electron. But rather, the electrons spend more time near the Cl atom than the H atom, giving the molecule a net dipole moment. The electrons are not distributed symmetrically about the two nuclei.

(*c*) The torque is given by Eq. 21-9a.



$$\tau = pE\sin\theta \ \rightarrow\ \tau_{\max} = pE = \left(3.4\times10^{-30}\,\text{C•m}\right)\left(2.5\times10^{4}\ \text{N/C}\right) = \boxed{8.5\times10^{-26}\,\text{N•m}}$$

(*d*) The energy needed from an external force is the change in potential energy. Use Eq. 21-10.

$$W = \Delta U = \left(-pE\cos\theta_{\text{final}}\right) - \left(-pE\cos\theta_{\text{initial}}\right) = pE\left(\cos\theta_{\text{initial}} - \cos\theta_{\text{final}}\right)$$

$$= \left(3.4\times10^{-30}\,\text{C•m}\right)\left(2.5\times10^{4}\ \text{N/C}\right)\left[1-\cos 45°\right] = \boxed{2.5\times10^{-26}\,\text{J}}$$

64. (*a*) From the symmetry in the diagram, we see that the resultant field will be in the *y* direction. The vertical components of the two fields add together, while the horizontal components cancel.

$$E_{\text{net}} = 2E\sin\phi = 2\frac{Q}{4\pi\varepsilon_0\left(r^2+\ell^2\right)}\frac{r}{\left(r^2+\ell^2\right)^{1/2}}$$

$$= \frac{2Qr}{4\pi\varepsilon_0\left(r^2+\ell^2\right)^{3/2}} \approx \frac{2Qr}{4\pi\varepsilon_0\left(r^3\right)} = \boxed{\frac{2Q}{4\pi\varepsilon_0 r^2}}$$

(*b*) Both charges are the same sign. A long distance away from the charges, they will look like a single charge of magnitude $2Q$, and so $E = k\dfrac{q}{r^2} = \dfrac{2Q}{4\pi\varepsilon_0 r^2}$.

65. (*a*) There will be a torque on the dipole, in a direction to decrease θ. That torque will give the dipole an angular acceleration, in the opposite direction of θ.

$$\tau = -pE\sin\theta = I\alpha \ \rightarrow\ \alpha = \frac{d^2\theta}{dt^2} = -\frac{pE}{I}\sin\theta$$

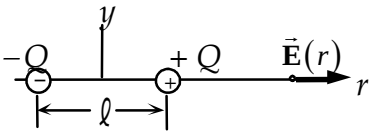
If θ is small, so that $\sin\theta \approx \theta$, then the equation is in the same form as Eq. 14-3, the equation of motion for the simple harmonic oscillator.

$$\frac{d^2\theta}{dt^2} = -\frac{pE}{I}\sin\theta \approx -\frac{pE}{I}\theta \quad \rightarrow \quad \frac{d^2\theta}{dt^2} + \frac{pE}{I}\theta = 0$$

(*b*) The frequency can be found from the coefficient of θ in the equation of motion.

$$\omega^2 = \frac{pE}{I} \quad \rightarrow \quad f = \boxed{\frac{1}{2\pi}\sqrt{\frac{pE}{I}}}$$



66. If the dipole is of very small extent, then the potential energy is a function of position, and so Eq. 21-10 gives $U(x) = -\vec{\mathbf{p}}\bullet\vec{\mathbf{E}}(x)$. Since the potential energy is known, we can use Eq. 8-7.

$$F_x = -\frac{dU}{dx} = -\frac{d}{dx}\left[-\vec{\mathbf{p}}\bullet\vec{\mathbf{E}}(x)\right] = \vec{\mathbf{p}}\bullet\frac{d\vec{\mathbf{E}}}{dx}$$

Since the field does not depend on the *y* or *z* coordinates, all other components of the force will be 0.

Thus $\vec{\mathbf{F}} = F_x\hat{\mathbf{i}} = \boxed{\left(\vec{\mathbf{p}}\bullet\frac{d\vec{\mathbf{E}}}{dx}\right)\hat{\mathbf{i}}}$.

67. (*a*) Along the *x* axis the fields from the two charges are parallel so the magnitude is found as follows.

$$E_{\text{net}} = E_{+Q} + E_{-Q} = \frac{Q}{4\pi\varepsilon_0\left(r-\frac{1}{2}\ell\right)^2} + \frac{(-Q)}{4\pi\varepsilon_0\left(r+\frac{1}{2}\ell\right)^2}$$

$$= \frac{Q\left[\left(r+\frac{1}{2}\ell\right)^2 - \left(r-\frac{1}{2}\ell\right)^2\right]}{4\pi\varepsilon_0\left(r+\frac{1}{2}\ell\right)^2\left(r-\frac{1}{2}\ell\right)^2}$$

$$= \frac{Q(2r\ell)}{4\pi\varepsilon_0\left(r+\frac{1}{2}\ell\right)^2\left(r-\frac{1}{2}\ell\right)^2} \approx \frac{Q(2r\ell)}{4\pi\varepsilon_0 r^4} = \frac{2Q\ell}{4\pi\varepsilon_0 r^3} = \boxed{\frac{1}{4\pi\varepsilon_0}\frac{2p}{r^3}}$$

The same result is obtained if the point is to the left of $-Q$.

(*b*) The electric field points in the same direction as the dipole moment vector.

68. Set the magnitude of the electric force equal to the magnitude of the force of gravity and solve for the distance.

$$F_{\text{E}} = F_{\text{G}} \quad \rightarrow \quad k\frac{e^2}{r^2} = mg \quad \rightarrow$$

$$r = e\sqrt{\frac{k}{mg}} = \left(1.602\times10^{-19}\,\text{C}\right)\sqrt{\frac{\left(8.988\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2\right)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(9.80\,\text{m/s}^2\right)}} = \boxed{5.08\,\text{m}}$$

69. Water has an atomic mass of 18, so 1 mole of water molecules has a mass of 18 grams. Each water molecule contains 10 protons.

$$65\text{kg}\left(\frac{6.02\times10^{23}\,\text{H}_2\text{O molecules}}{0.018\,\text{kg}}\right)\left(\frac{10\,\text{protons}}{1\,\text{molecule}}\right)\left(\frac{1.60\times10^{-19}\,\text{C}}{\text{proton}}\right) = \boxed{3.5\times10^{9}\,\text{C}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

70. Calculate the total charge on all electrons in 3.0 g of copper, and compare $38\mu\text{C}$ to that value.

$$\text{Total electron charge} = 3.0\,\text{g}\left(\frac{1\,\text{mole}}{63.5\,\text{g}}\right)\left(\frac{6.02\times10^{23}\,\text{atoms}}{\text{mole}}\right)\left(\frac{29\,\text{e}}{\text{atoms}}\right)\left(\frac{1.602\times10^{-19}\,\text{C}}{1\,\text{e}}\right) = 1.32\times10^{5}\,\text{C}$$

$$\text{Fraction lost} = \frac{38\times10^{-6}\,\text{C}}{1.32\times10^{5}\,\text{C}} = \boxed{2.9\times10^{-10}}$$

71. Use Eq. 21-4a to calculate the magnitude of the electric charge on the Earth.

$$E = k\frac{Q}{r^2} \;\rightarrow\; Q = \frac{Er^2}{k} = \frac{(150\ \text{N/C})\left(6.38\times10^{6}\,\text{m}\right)^2}{8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2} = \boxed{6.8\times10^{5}\,\text{C}}$$

Since the electric field is pointing towards the Earth's center, the charge must be negative.

72. (*a*) From problem 71, we know that the electric field is pointed towards the Earth's center. Thus an electron in such a field would experience an upwards force of magnitude $F_{\text{E}} = eE$. The force of gravity on the electron will be negligible compared to the electric force.

$$F_{\text{E}} = eE = ma \;\rightarrow$$

$$a = \frac{eE}{m} = \frac{\left(1.602\times10^{-19}\,\text{C}\right)(150\,\text{N/C})}{\left(9.11\times10^{-31}\,\text{kg}\right)} = 2.638\times10^{13}\ \text{m/s}^2 \approx \boxed{2.6\times10^{13}\ \text{m/s}^2\text{, up}}$$

(*b*) A proton in the field would experience a downwards force of magnitude $F_{\text{E}} = eE$. The force of gravity on the proton will be negligible compared to the electric force.

$$F_{\text{E}} = eE = ma \;\rightarrow$$

$$a = \frac{eE}{m} = \frac{\left(1.602\times10^{-19}\,\text{C}\right)(150\,\text{N/C})}{\left(1.67\times10^{-27}\,\text{kg}\right)} = 1.439\times10^{10}\ \text{m/s}^2 \approx \boxed{1.4\times10^{10}\ \text{m/s}^2\text{, down}}$$

(*c*) Electron: $\dfrac{a}{g} = \dfrac{2.638\times10^{13}\ \text{m/s}^2}{9.80\,\text{m/s}^2} \approx \boxed{2.7\times10^{12}}$; Proton: $\dfrac{a}{g} = \dfrac{1.439\times10^{10}\ \text{m/s}^2}{9.80\,\text{m/s}^2} \approx \boxed{1.5\times10^{9}}$

73. For the droplet to remain stationary, the magnitude of the electric force on the droplet must be the same as the weight of the droplet. The mass of the droplet is found from its volume times the density of water. Let *n* be the number of excess electrons on the water droplet.

$$F_{\text{E}} = |q|E = mg \;\rightarrow\; neE = \tfrac{4}{3}\pi r^3\rho g \;\rightarrow$$

$$n = \frac{4\pi r^3\rho g}{3eE} = \frac{4\pi\left(1.8\times10^{-5}\,\text{m}\right)^3\left(1.00\times10^{3}\ \text{kg/m}^3\right)\left(9.80\,\text{m/s}^2\right)}{3\left(1.602\times10^{-19}\,\text{C}\right)(150\,\text{N/C})} = 9.96\times10^{6} \approx \boxed{1.0\times10^{7}\ \text{electrons}}$$

74. There are four forces to calculate. Call the rightward direction the positive direction. The value of *k* is $8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2$ and the value of *e* is $1.602\times10^{-19}\,\text{C}$.

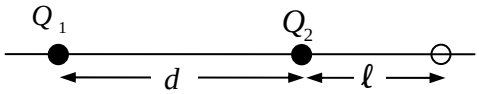
$$F_{\text{net}} = F_{\text{CH}} + F_{\text{CN}} + F_{\text{OH}} + F_{\text{ON}} = \frac{k(0.40e)(0.20e)}{\left(1\times10^{-9}\,\text{m}\right)^2}\left[-\frac{1}{(0.30)^2} + \frac{1}{(0.40)^2} + \frac{1}{(0.18)^2} - \frac{1}{(0.28)^2}\right]$$

$$= 2.445\times10^{-10}\,\text{N} \approx \boxed{2.4\times10^{-10}\,\text{N}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

75. Set the Coulomb electrical force equal to the Newtonian gravitational force on one of the bodies (the Moon).

$$F_E = F_G \rightarrow k\frac{Q^2}{r_{orbit}^2} = G\frac{M_{Moon}M_{Earth}}{r_{orbit}^2} \rightarrow$$



$$Q = \sqrt{\frac{GM_{Moon}M_{Earth}}{k}} = \sqrt{\frac{\left(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(7.35\times10^{22}\ \text{kg}\right)\left(5.98\times10^{24}\ \text{kg}\right)}{\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)}} = \boxed{5.71\times10^{13}\ \text{C}}$$

76. The electric force must be a radial force in order for the electron to move in a circular orbit.

$$F_E = F_{radial} \rightarrow k\frac{Q^2}{r_{orbit}^2} = \frac{mv^2}{r_{orbit}} \rightarrow$$

$$r_{orbit} = k\frac{Q^2}{mv^2} = \left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(1.602\times10^{-19}\ \text{C}\right)^2}{\left(9.109\times10^{-31}\ \text{kg}\right)\left(2.2\times10^{6}\ \text{m/s}\right)^2} = \boxed{5.2\times10^{-11}\ \text{m}}$$

77. Because of the inverse square nature of the electric field, any location where the field is zero must be closer to the weaker charge (Q_2). Also, in between the two charges, the fields due to the two charges are parallel to each other and cannot cancel. Thus the only places where the field can be zero are closer to the weaker charge, but not between them. In the diagram, this means that ℓ must be positive.

$$E = -k\frac{|Q_2|}{\ell^2} + k\frac{Q_1}{(\ell+d)^2} = 0 \rightarrow |Q_2|(\ell+d)^2 = Q_1\ell^2 \rightarrow$$

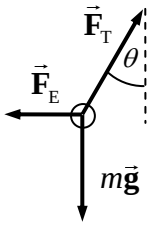
$$\ell = \frac{\sqrt{|Q_2|}}{\sqrt{Q_1}-\sqrt{|Q_2|}}d = \frac{\sqrt{5.0\times10^{-6}\ \text{C}}}{\sqrt{2.5\times10^{-5}\ \text{C}}-\sqrt{5.0\times10^{-6}\ \text{C}}}(2.0\ \text{m}) = \boxed{\begin{matrix}1.6\ \text{m from } Q_2,\\ 3.6\ \text{m from } Q_1\end{matrix}}$$

78. We consider that the sock is only acted on by two forces – the force of gravity, acting downward, and the electrostatic force, acting upwards. If charge Q is on the sweater, then it will create an electric field of $E = \frac{\sigma}{2\varepsilon_0} = \frac{Q/A}{2\varepsilon_0}$, where A is the surface area of one side of the sweater. The same magnitude of charge will be on the sock, and so the attractive force between the sweater and sock is $F_E = QE = \frac{Q^2}{2\varepsilon_0 A}$. This must be equal to the weight of the sweater. We estimate the sweater area as 0.10 m^2, which is roughly a square foot.

$$F_E = QE = \frac{Q^2}{2\varepsilon_0 A} = mg \rightarrow$$

$$Q = \sqrt{2\varepsilon_0 Amg} = \sqrt{2\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(0.10\ \text{m}^2\right)\left(0.040\ \text{kg}\right)\left(9.80\ \text{m/s}^2\right)} = \boxed{8\times10^{-7}\ \text{C}}$$

79. The sphere will oscillate sinusoidally about the equilibrium point, with an amplitude of 5.0 cm. The angular frequency of the sphere is given by $\omega = \sqrt{k/m} = \sqrt{126\ \text{N/m}/0.650\ \text{kg}} = 13.92\ \text{rad/s}$. The distance of the sphere from the table is given by $r = \left[0.150 - 0.0500\cos\left(13.92t\right)\right]\text{m}$. Use this distance



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

and the charge to give the electric field value at the tabletop. That electric field will point upwards at all times, towards the negative sphere.

$$E = k\frac{|Q|}{r^2} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.00\times10^{-6}\,\text{C}\right)}{\left[0.150-0.0500\cos\left(13.92t\right)\right]^2\,\text{m}^2} = \frac{2.70\times10^4}{\left[0.150-0.0500\cos\left(13.92t\right)\right]^2}\,\text{N/C}$$

$$= \boxed{\frac{1.08\times10^7}{\left[3.00-\cos\left(13.9t\right)\right]^2}\,\text{N/C, upwards}}$$

80. The wires form two sides of an isosceles triangle, and so the two charges are separated by a distance $\ell = 2\left(78\,\text{cm}\right)\sin 26° = 68.4\,\text{cm}$ and are directly horizontal from each other. Thus the electric force on each charge is horizontal. From the free-body diagram for one of the spheres, write the net force in both the horizontal and vertical directions and solve for the electric force. Then write the electric force by Coulomb's law, and equate the two expressions for the electric force to find the charge.

$$\sum F_y = F_\text{T}\cos\theta - mg = 0 \;\rightarrow\; F_\text{T} = \frac{mg}{\cos\theta}$$

$$\sum F_x = F_\text{T}\sin\theta - F_\text{E} = 0 \;\rightarrow\; F_\text{E} = F_\text{T}\sin\theta = \frac{mg}{\cos\theta}\sin\theta = mg\tan\theta$$

$$F_\text{E} = k\frac{\left(Q/2\right)^2}{\ell^2} = mg\tan\theta \;\rightarrow\; Q = 2\ell\sqrt{\frac{mg\tan\theta}{k}}$$

$$= 2\left(0.684\,\text{m}\right)\sqrt{\frac{\left(24\times10^{-3}\,\text{kg}\right)\left(9.80\,\text{m/s}^2\right)\tan 26°}{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)}} = 4.887\times10^{-6}\,\text{C} \approx \boxed{4.9\times10^{-6}\,\text{C}}$$

81. The electric field at the surface of the pea is given by Eq. 21-4a. Solve that equation for the charge.

$$E = k\frac{Q}{r^2} \;\rightarrow\; Q = \frac{Er^2}{k} = \frac{\left(3\times10^6\ \text{N/C}\right)\left(3.75\times10^{-3}\,\text{m}\right)^2}{8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2} = \boxed{5\times10^{-9}\,\text{C}}$$

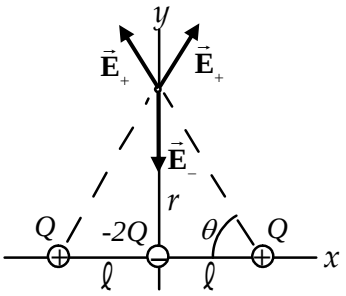
This corresponds to about 3 billion electrons.

82. There will be a rightward force on Q_1 due to Q_2, given by Coulomb's law. There will be a leftward force on Q_1 due to the electric field created by the parallel plates. Let right be the positive direction.

$$\sum F = k\frac{|Q_1Q_2|}{x^2} - |Q_1|E$$

$$= \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(6.7\times10^{-6}\,\text{C}\right)\left(1.8\times10^{-6}\,\text{C}\right)}{\left(0.34\,\text{m}\right)^2} - \left(6.7\times10^{-6}\,\text{C}\right)\left(7.3\times10^4\ \text{N/C}\right)$$

$$= \boxed{0.45\,\text{N, right}}$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

83. The weight of the sphere is the density times the volume. The electric force is given by Eq. 21-1, with both spheres having the same charge, and the separation distance equal to their diameter.

$$mg = k\frac{Q^2}{(d)^2} \quad \rightarrow \quad \rho\tfrac{4}{3}\pi r^3 g = \frac{kQ^2}{(2r)^2} \quad \rightarrow$$

$$Q = \sqrt{\frac{16\rho\pi g r^5}{3k}} = \sqrt{\frac{16\left(35\,\text{kg/m}^3\right)\pi\left(9.80\,\text{m/s}^2\right)\left(1.0\times10^{-2}\,\text{m}\right)^5}{3\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)}} = \boxed{8.0\times10^{-9}\,\text{C}}$$

84. From the symmetry, we see that the resultant field will be in the *y* direction. So we take the vertical component of each field.

$$E_{\text{net}} = 2E_+\sin\theta - E_- = 2\frac{Q}{4\pi\varepsilon_0\left(r^2+\ell^2\right)}\frac{r}{\left(r^2+\ell^2\right)^{1/2}} - \frac{2Q}{4\pi\varepsilon_0 r^2}$$

$$= \frac{2Q}{4\pi\varepsilon_0}\left[\frac{r}{\left(r^2+\ell^2\right)^{3/2}} - \frac{1}{r^2}\right]$$

$$= \frac{2Q}{4\pi\varepsilon_0\left(r^2+\ell^2\right)^{3/2}r^2}\left[r^3 - \left(r^2+\ell^2\right)^{3/2}\right]$$

$$= \frac{2Qr^3\left[1-\left(1+\dfrac{\ell^2}{r^2}\right)^{3/2}\right]}{4\pi\varepsilon_0 r^5\left(1+\dfrac{\ell^2}{r^2}\right)^{3/2}}$$

Use the binomial expansion, assuming $r \gg \ell$.

$$E_{\text{net}} = \frac{2Qr^3\left[1-\left(1+\dfrac{\ell^2}{r^2}\right)^{3/2}\right]}{4\pi\varepsilon_0 r^5\left(1+\dfrac{\ell^2}{r^2}\right)^{3/2}} \approx \frac{2Qr^3\left[1-\left(1+\frac{3}{2}\dfrac{\ell^2}{r^2}\right)\right]}{4\pi\varepsilon_0 r^5\left(1+\frac{3}{2}\dfrac{\ell^2}{r^2}\right)} = \frac{2Qr^3\left(-\frac{3}{2}\dfrac{\ell^2}{r^2}\right)}{4\pi\varepsilon_0 r^5(1)} = \boxed{-\frac{3Q\ell^2}{4\pi\varepsilon_0 r^4}}$$

Notice that the field points toward the negative charges.

85. This is a constant acceleration situation, similar to projectile motion in a uniform gravitational field. Let the width of the plates be ℓ, the vertical gap between the plates be *h*, and the initial velocity be v_0. Notice that the vertical motion has a maximum displacement of *h*/2. Let upwards be the positive vertical direction. We calculate the vertical acceleration produced by the electric field and the time *t* for the electron to cross the region of the field. We then use constant acceleration equations to solve for the angle.

$$F_y = ma_y = qE = -eE \quad \rightarrow \quad a_y = -\frac{eE}{m} \ ; \ \ell = v_0\cos\theta_0(t) \quad \rightarrow \quad t = \frac{\ell}{v_0\cos\theta_0}$$

$$v_{\substack{y\\ \text{top}}} = v_{0y} + a_y t_{\text{top}} \quad \rightarrow \quad 0 = v_0\sin\theta_0 - \frac{eE}{m}\left(\tfrac{1}{2}\frac{\ell}{v_0\cos\theta_0}\right) \quad \rightarrow \quad v_0^2 = \frac{eE}{2m}\left(\frac{\ell}{\sin\theta_0\cos\theta_0}\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$y_{\text{top}} = y_0 + v_{0y}t_{\text{top}} + \tfrac{1}{2}a_y t^2 \quad \rightarrow \quad \tfrac{1}{2}h = v_0 \sin\theta_0 \left(\tfrac{1}{2}\frac{\ell}{v_0 \cos\theta_0} \right) - \tfrac{1}{2}\frac{eE}{m}\left(\tfrac{1}{2}\frac{\ell}{v_0 \cos\theta_0} \right)^2 \quad \rightarrow$$

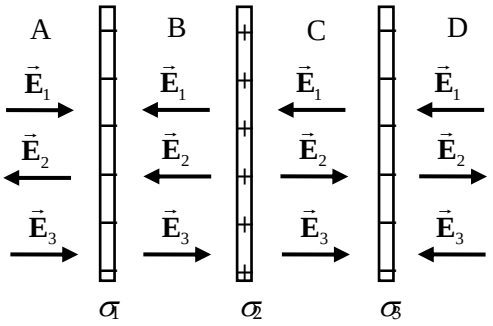
$$h = \ell \tan\theta_0 - \frac{eE\ell^2}{4m\cos^2\theta_0}\frac{1}{v_0^2}^{\,2} = \ell \tan\theta_0 - \frac{eE\ell^2}{4m\cos^2\theta_0}\frac{1}{\dfrac{eE}{2m}\left(\dfrac{\ell}{\sin\theta_0 \cos\theta_0}\right)} = \ell \tan\theta_0 - \tfrac{1}{2}\ell \tan\theta_0$$

$$h = \tfrac{1}{2}\ell \tan\theta_0 \quad \rightarrow \quad \theta_0 = \tan^{-1}\frac{2h}{\ell} = \tan^{-1}\frac{2(1.0\,\text{cm})}{6.0\,\text{cm}} = \boxed{18^\circ}$$

86. (*a*) The electric field from the long wire is derived in Example 21-11.

$$E = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{r}, \text{ radially away from the wire}$$

(*b*) The force on the electron will point radially in, producing a centripetal acceleration.



$$|F| = |qE| = \frac{e}{2\pi\varepsilon_0}\frac{\lambda}{r} = \frac{mv^2}{r} \quad \rightarrow$$

$$v = \sqrt{2\frac{1}{4\pi\varepsilon_0}\frac{e\lambda}{m}} = \sqrt{2\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.14\times10^{-6}\,\text{C/m}\right)}{9.11\times10^{-31}\,\text{kg}}}$$

$$= \boxed{2.1\times10^7\ \text{m/s}}$$

Note that this speed is independent of *r*.

87. We treat each of the plates as if it were infinite, and then use Eq. 21-7. The fields due to the first and third plates point towards their respective plates, and the fields due to the second plate point away from it. See the diagram. The directions of the fields are given by the arrows, so we calculate the magnitude of the fields from Eq. 21-7. Let the positive direction be to the right.

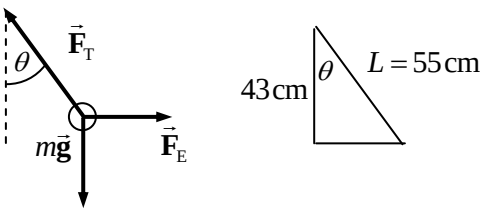
$$E_{\text{A}} = E_1 - E_2 + E_3 = \frac{|\sigma_1|}{2\varepsilon_0} - \frac{\sigma_2}{2\varepsilon_0} + \frac{|\sigma_1|}{2\varepsilon_0}$$

$$= \frac{(0.50 - 0.25 + 0.35)\times10^{-6}\,\text{C/m}^2}{2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = \boxed{3.4\times10^4\ \text{N/C, to the right}}$$

$$E_{\text{B}} = -E_1 - E_2 + E_3 = -\frac{|\sigma_1|}{2\varepsilon_0} - \frac{\sigma_2}{2\varepsilon_0} + \frac{|\sigma_1|}{2\varepsilon_0}$$

$$= \frac{(-0.50 - 0.25 + 0.35)\times10^{-6}\,\text{C/m}^2}{2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = -2.3\times10^4\ \text{N/C} = \boxed{2.3\times10^4\ \text{N/C to the left}}$$

$$E_{\text{C}} = -E_1 + E_2 + E_3 = -\frac{|\sigma_1|}{2\varepsilon_0} - \frac{\sigma_2}{2\varepsilon_0} + \frac{|\sigma_1|}{2\varepsilon_0}$$



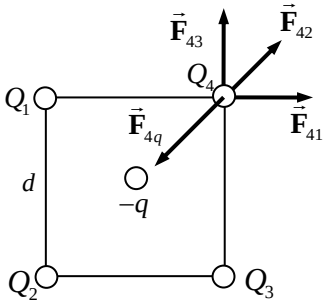
$$= \frac{(-0.50 + 0.25 + 0.35)\times10^{-6}\,\text{C/m}^2}{2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = \boxed{5.6\times10^3\ \text{N/C to the right}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E_D = -E_1 + E_2 - E_3 = -\frac{|\sigma_1|}{2\varepsilon_0} - \frac{\sigma_2}{2\varepsilon_0} + \frac{|\sigma_1|}{2\varepsilon_0}$$

$$= \frac{(-0.50 + 0.25 - 0.35)\times 10^{-6}\ \text{C/m}^2}{2\left(8.85\times 10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)} = -3.4\times 10^4\ \text{N/C} = \boxed{3.4\times 10^3\ \text{N/C to the left}}$$

88. Since the electric field exerts a force on the charge in the same direction as the electric field, the charge is positive. Use the free-body diagram to write the equilibrium equations for both the horizontal and vertical directions, and use those equations to find the magnitude of the charge.



$$\theta = \cos^{-1}\frac{43\,\text{cm}}{55\,\text{cm}} = 38.6^\circ$$

$$\sum F_x = F_E - F_T\sin\theta = 0 \ \rightarrow\ F_E = F_T\sin\theta = QE$$

$$\sum F_y = F_T\cos\theta - mg = 0 \ \rightarrow\ F_T = \frac{mg}{\cos\theta} \ \rightarrow\ QE = mg\tan\theta$$

$$Q = \frac{mg\tan\theta}{E} = \frac{\left(1.0\times 10^{-3}\text{kg}\right)\left(9.80\,\text{m/s}^2\right)\tan 38.6^\circ}{\left(1.5\times 10^4\ \text{N/C}\right)} = \boxed{5.2\times 10^{-7}\,\text{C}}$$

89. A negative charge must be placed at the center of the square. Let $Q = 8.0\,\mu\text{C}$ be the charge at each corner, let $-q$ be the magnitude of negative charge in the center, and let $d = 9.2\,\text{cm}$ be the side length of the square. By the symmetry of the problem, if we make the net force on one of the corner charges be zero, the net force on each other corner charge will also be zero.

$$F_{41} = k\frac{Q^2}{d^2} \ \rightarrow\ F_{41x} = k\frac{Q^2}{d^2}\ ,\ F_{41y} = 0$$

$$F_{42} = k\frac{Q^2}{2d^2} \ \rightarrow\ F_{42x} = k\frac{Q^2}{2d^2}\cos 45^\circ = k\frac{\sqrt{2}Q^2}{4d^2}\ ,\ F_{42y} = k\frac{\sqrt{2}Q^2}{4d^2}$$

$$F_{43} = k\frac{Q^2}{d^2} \ \rightarrow\ F_{43x} = 0\ ,\ F_{43y} = k\frac{Q^2}{d^2}$$

$$F_{4q} = k\frac{qQ}{d^2/2} \ \rightarrow\ F_{4qx} = -k\frac{2qQ}{d^2}\cos 45^\circ = -k\frac{\sqrt{2}qQ}{d^2} = F_{4qy}$$

The net force in each direction should be zero.

$$\sum F_x = k\frac{Q^2}{d^2} + k\frac{\sqrt{2}Q^2}{4d^2} + 0 - k\frac{\sqrt{2}qQ}{d^2} = 0 \ \rightarrow$$

$$q = Q\left(\frac{1}{\sqrt{2}} + \frac{1}{4}\right) = \left(8.0\times 10^{-6}\text{C}\right)\left(\frac{1}{\sqrt{2}} + \frac{1}{4}\right) = 7.66\times 10^{-6}\text{C}$$

So the charge to be placed is $-q = \boxed{-7.7\times 10^{-6}\text{C}}$.

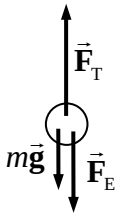
This is an unstable equilibrium. If the center charge were slightly displaced, say towards the right, then it would be closer to the right charges than the left, and would be attracted more to the right. Likewise the positive charges on the right side of the square would be closer to it and would be attracted more to it, moving from their corner positions. The system would not have a tendency to return to the symmetric shape, but rather would have a tendency to move away from it if disturbed.

90. (*a*) The force of sphere B on sphere A is given by Coulomb's law.

$$F_{AB} = \boxed{\frac{kQ^2}{R^2}, \text{ away from B}}$$



(*b*) The result of touching sphere B to uncharged sphere C is that the charge on B is shared between the two spheres, and so the charge on B is reduced to $Q/2$. Again use Coulomb's law.

$$F_{AB} = k\frac{QQ/2}{R^2} = \boxed{\frac{kQ^2}{2R^2}, \text{ away from B}}$$

(*c*) The result of touching sphere A to sphere C is that the charge on the two spheres is shared, and so the charge on A is reduced to $3Q/4$. Again use Coulomb's law.

$$F_{AB} = k\frac{(3Q/4)(Q/2)}{R^2} = \boxed{\frac{3kQ^2}{8R^2}, \text{ away from B}}$$

91. (*a*) The weight of the mass is only about 2 N. Since the tension in the string is more than that, there must be a downward electric force on the positive charge, which means that the electric field must be pointed down. Use the free-body diagram to write an expression for the magnitude of the electric field.

$$\sum F = F_T - mg - F_E = 0 \;\rightarrow\; F_E = QE = F_T - mg \;\rightarrow$$

$$E = \frac{F_T - mg}{Q} = \frac{5.18\,\text{N} - (0.210\,\text{kg})(9.80\,\text{m/s}^2)}{3.40\times10^{-7}\,\text{C}} = \boxed{9.18\times10^6\,\text{N/C}}$$

(*b*) Use Eq. 21-7.

$$E = \frac{\sigma}{2\varepsilon_0} \;\rightarrow\; \sigma = 2E\varepsilon_0 = 2(9.18\times10^6\,\text{N/C})(8.854\times10^{-12}) = \boxed{1.63\times10^{-4}\,\text{C/m}^2}$$

92. (*a*) The force will be attractive. Each successive charge is another distance *d* farther than the previous charge. The magnitude of the charge on the electron is *e*.

$$F = k\frac{eQ}{(d)^2} + k\frac{eQ}{(2d)^2} + k\frac{eQ}{(3d)^2} + k\frac{eQ}{(4d)^2} + \cdots = k\frac{eQ}{d^2}\left(\frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \cdots\right)$$

$$= k\frac{eQ}{d^2}\sum_{n=1}^{\infty}\frac{1}{n^2} = \frac{1}{4\pi\varepsilon_0}\frac{eQ}{d^2}\frac{\pi^2}{6} = \boxed{\frac{\pi eQ}{24\varepsilon_0 d^2}}$$

(*b*) Now the closest *Q* is a distance of 3*d* from the electron.

$$F = k\frac{eQ}{(3d)^2} + k\frac{eQ}{(4d)^2} + k\frac{eQ}{(5d)^2} + k\frac{eQ}{(6d)^2} + \cdots = k\frac{eQ}{d^2}\left(\frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \frac{1}{6^2} + \cdots\right)$$

$$= k\frac{eQ}{d^2}\sum_{n=3}^{\infty}\frac{1}{n^2} = k\frac{eQ}{d^2}\left[\left(\sum_{n=1}^{\infty}\frac{1}{n^2}\right) - \frac{1}{1^2} - \frac{1}{2^2}\right] = k\frac{eQ}{d^2}\left[\frac{\pi^2}{6} - \frac{5}{4}\right] = \boxed{\frac{eQ}{4\pi\varepsilon_0 d^2}\left[\frac{\pi^2}{6} - \frac{5}{4}\right]}$$

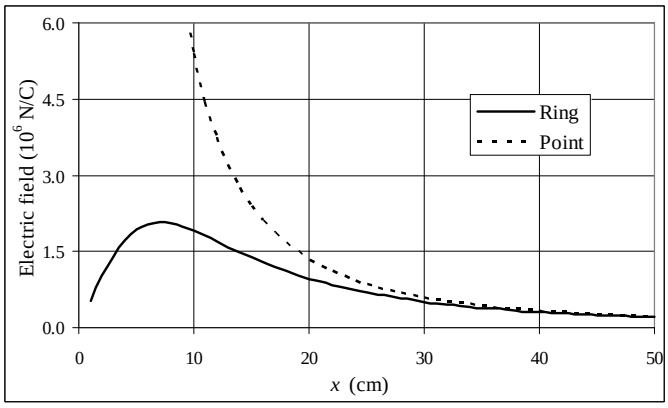
93. (*a*) Take $\frac{dE}{dx}$, set it equal to 0, and solve for the location of the maximum.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Qx}{\left(x^2+a^2\right)^{3/2}}$$

$$\frac{dE}{dx} = \frac{Q}{4\pi\varepsilon_0}\left[\frac{\left(x^2+a^2\right)^{3/2} - x\frac{3}{2}\left(x^2+a^2\right)^{1/2}2x}{\left(x^2+a^2\right)^3}\right] = \frac{Q}{4\pi\varepsilon_0}\frac{\left(a^2-2x^2\right)}{\left(x^2+a^2\right)^{5/2}} = 0 \;\rightarrow\; a^2-2x^2=0 \;\rightarrow$$

$$x = \frac{a}{\sqrt{2}} = \frac{10.0\,\text{cm}}{\sqrt{2}} = \boxed{7.07\,\text{cm}}$$

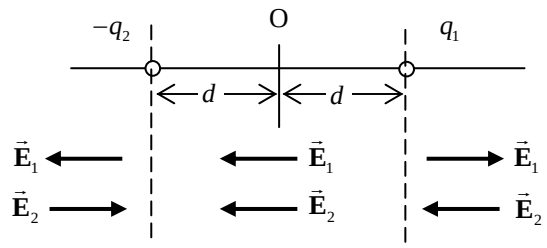


(*b*) Yes, the maximum of the graph does coincide with the analytic maximum. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH21.XLS," on tab "Problem 21.93b."

(*c*) The field due to the ring is

$$E_{\text{ring}} = \frac{1}{4\pi\varepsilon_0}\frac{Qx}{\left(x^2+a^2\right)^{3/2}}.$$

(*d*) The field due to the point charge is $E_{\text{ring}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{x^2}$. Both are plotted on the graph. The graph shows that the two fields converge at large distances from the origin. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH21.XLS," on tab "Problem 21.93cd."



(*e*) According to the spreadsheet, $E_{\text{ring}} = 0.9E_{\text{point}}$ at about $\boxed{37\text{ cm}}$. An analytic calculation gives the same result.

$$E_{\text{ring}} = 0.9E_{\text{point}} \;\rightarrow\; \frac{1}{4\pi\varepsilon_0}\frac{Qx}{\left(x^2+a^2\right)^{3/2}} = 0.9\frac{1}{4\pi\varepsilon_0}\frac{Q}{x^2} \;\rightarrow$$

$$x^3 = 0.9\left(x^2+a^2\right)^{3/2} = 0.9x^3\left(1+\frac{a^2}{x^2}\right)^{3/2} \;\rightarrow\; x = \frac{a}{\sqrt{\left(\frac{1}{0.9}\right)^{2/3}-1}} = \frac{10.0\,\text{cm}}{\sqrt{\left(\frac{1}{0.9}\right)^{2/3}-1}} = 37.07\,\text{cm}$$

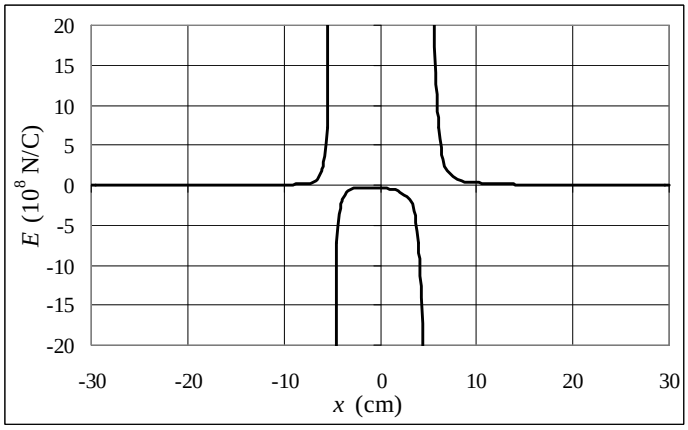
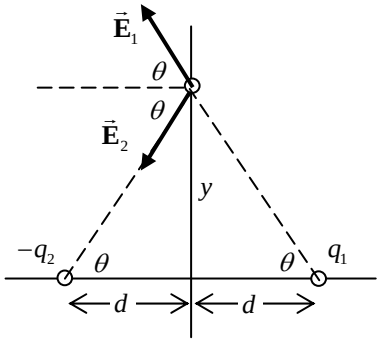
94. (*a*) Let $q_1 = 8.00\,\mu\text{C}$, $q_2 = 2.00\,\mu\text{C}$, and $d = 0.0500\,\text{m}$. The field directions due to the charges are shown in the diagram. We take care with the signs of the *x* coordinate used to calculate the magnitude of the field.



$$E_{x<-d} = E_2 - E_1 = \frac{1}{4\pi\varepsilon_0}\frac{q_2}{\left(|x|-d\right)^2} - \frac{1}{4\pi\varepsilon_0}\frac{q_1}{\left(|x|+d\right)^2} = \frac{1}{4\pi\varepsilon_0}\frac{q_2}{\left(-x-d\right)^2} - \frac{1}{4\pi\varepsilon_0}\frac{q_1}{\left(-x+d\right)^2}$$

$$E_{-d<x<0} = -E_2 - E_1 = -\frac{1}{4\pi\varepsilon_0}\frac{q_2}{\left(d-|x|\right)^2} - \frac{1}{4\pi\varepsilon_0}\frac{q_1}{\left(|x|+d\right)^2} = -\frac{1}{4\pi\varepsilon_0}\frac{q_2}{\left(d+x\right)^2} - \frac{1}{4\pi\varepsilon_0}\frac{q_1}{\left(-x+d\right)^2}$$



$$E_{0<x<d} = -E_2 - E_1 = -\frac{1}{4\pi\varepsilon_0}\frac{q_2}{\left(d+x\right)^2} - \frac{1}{4\pi\varepsilon_0}\frac{q_1}{\left(d-x\right)^2}$$

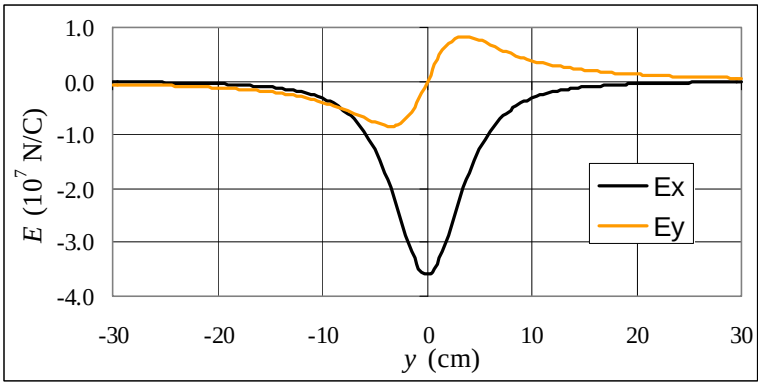
$$E_{d<x} = E_1 - E_2 = \frac{1}{4\pi\varepsilon_0}\frac{q_1}{\left(x-d\right)^2} - \frac{1}{4\pi\varepsilon_0}\frac{q_2}{\left(x+d\right)^2}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH21.XLS," on tab "Problem 21.94a."

(*b*) Now for points on the y axis. See the diagram for this case.

$$E_x = -E_1\cos\theta - E_2\cos\theta$$

$$= -\frac{1}{4\pi\varepsilon_0}\frac{q_1\cos\theta}{\left(d^2+y^2\right)} - \frac{1}{4\pi\varepsilon_0}\frac{q_2\cos\theta}{\left(d^2+y^2\right)}$$



$$= -\frac{1}{4\pi\varepsilon_0}\frac{\left(q_1+q_2\right)}{\left(d^2+y^2\right)}\cos\theta = -\frac{1}{4\pi\varepsilon_0}\frac{\left(q_1+q_2\right)}{\left(d^2+y^2\right)}\frac{d}{\sqrt{d^2+y^2}}$$

$$= -\frac{1}{4\pi\varepsilon_0}\frac{\left(q_1+q_2\right)d}{\left(d^2+y^2\right)^{3/2}}$$

$$E_y = E_1\sin\theta - E_2\sin\theta = \frac{1}{4\pi\varepsilon_0}\frac{q_1\sin\theta}{\left(d^2+y^2\right)} - \frac{1}{4\pi\varepsilon_0}\frac{q_2\sin\theta}{\left(d^2+y^2\right)}$$

$$= \frac{1}{4\pi\varepsilon_0}\frac{\left(q_1-q_2\right)}{\left(d^2+y^2\right)}\sin\theta = \frac{1}{4\pi\varepsilon_0}\frac{\left(q_1-q_2\right)}{\left(d^2+y^2\right)}\frac{y}{\sqrt{d^2+y^2}} = \frac{1}{4\pi\varepsilon_0}\frac{\left(q_1-q_2\right)y}{\left(d^2+y^2\right)^{3/2}}$$

CHAPTER 22: Gauss's Law

Responses to Questions

1. No. If the net electric flux through a surface is zero, then the net charge contained in the surface is zero. However, there may be charges both inside and outside the surface that affect the electric field at the surface. The electric field could point outward from the surface at some points and inward at others. Yes. If the electric field is zero for all points on the surface, then the net flux through the surface must be zero and no net charge is contained within the surface.

2. No. The electric field in the expression for Gauss's law refers to the *total* electric field, not just the electric field due to any enclosed charge. Notice, though, that if the electric field is due to a charge outside the Gaussian surface, then the net flux through the surface due to this charge will be zero.

3. The electric flux will be the same. The flux is equal to the net charge enclosed by the surface divided by ε_0. If the same charge is enclosed, then the flux is the same, regardless of the shape of the surface.

4. The net flux will be zero. An electric dipole consists of two charges that are equal in magnitude but opposite in sign, so the net charge of an electric dipole is zero. If the closed surface encloses a zero net charge, than the net flux through it will be zero.

5. Yes. If the electric field is zero for all points on the surface, then the integral of $\vec{\mathbf{E}} \cdot d\vec{\mathbf{A}}$ over the surface will be zero, the flux through the surface will be zero, and no net charge will be contained in the surface. No. If a surface encloses no net charge, then the net electric flux through the surface will be zero, but the electric field is not necessarily zero for all points on the surface. The integral of $\vec{\mathbf{E}} \cdot d\vec{\mathbf{A}}$ over the surface must be zero, but the electric field itself is not required to be zero. There may be charges outside the surface that will affect the values of the electric field at the surface.

6. The electric flux through a surface is the scalar (dot) product of the electric field vector and the area vector of the surface. Thus, in magnitude, $\Phi_E = EA\cos\theta$. By analogy, the gravitational flux through a surface would be the product of the gravitational field (or force per unit mass) and the area, or $\Phi_g = gA\cos\theta$. Any mass, such as a planet, would be a "sink" for gravitational field. Since there is not "anti-gravity" there would be no sources.

7. No. Gauss's law is most useful in cases of high symmetry, where a surface can be defined over which the electric field has a constant value and a constant relationship to the direction of the outward normal to the surface. Such a surface cannot be defined for an electric dipole.

8. When the ball is inflated and charge is distributed uniformly over its surface, the field inside is zero. When the ball is collapsed, there is no symmetry to the charge distribution, and the calculation of the electric field strength and direction inside the ball is difficult (and will most likely give a non-zero result).

9. For an infinitely long wire, the electric field is radially outward from the wire, resulting from contributions from all parts of the wire. This allows us to set up a Gaussian surface that is cylindrical, with the cylinder axis parallel to the wire. This surface will have zero flux through the top and bottom of the cylinder, since the net electric field and the outward surface normal are perpendicular at all points over the top and bottom. In the case of a short wire, the electric field is not radially outward from the wire near the ends; it curves and points directly outward along the axis of

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

the wire at both ends. We cannot define a useful Gaussian surface for this case, and the electric field must be computed directly.

10. In Example 22-6, there is no flux through the flat ends of the cylindrical Gaussian surface because the field is directed radially outward from the wire. If instead the wire extended only a short distance past the ends of the cylinder, there would be a component of the field through the ends of the cylinder. The result of the example would be altered because the value of the field at a given point would now depend not only on the radial distance from the wire but also on the distance from the ends.

11. The electric flux through the sphere remains the same, since the same charge is enclosed. The electric field at the surface of the sphere is changed, because different parts of the sphere are now at different distances from the charge. The electric field will not have the same magnitude for all parts of the sphere, and the direction of the electric field will not be parallel to the outward normal for all points on the surface of the sphere. The electric field will be stronger on the side closer to the charge and weaker on the side further from the charge.

12. (*a*) A charge of $(Q - q)$ will be on the outer surface of the conductor. The total charge Q is placed on the conductor but since $+q$ will reside on the inner surface, the leftover, $(Q - q)$, will reside on the outer surface.
(*b*) A charge of $+q$ will reside on the inner surface of the conductor since that amount is attracted by the charge $-q$ in the cavity. (Note that E must be zero inside the conductor.)

13. Yes. The charge q will induce a charge $-q$ on the inside surface of the thin metal shell, leaving the outside surface with a charge $+q$. The charge Q outside the sphere will feel the same electric force as it would if the metal shell were not present.

14. The total flux through the balloon's surface will not change because the enclosed charge does not change. The flux per unit surface area will decrease, since the surface area increases while the total flux does not change.

Solutions to Problems

1. The electric flux of a uniform field is given by Eq. 22-1b.

(*a*) $\Phi_E = \vec{\mathbf{E}} \cdot \vec{\mathbf{A}} = EA\cos\theta = (580\,\text{N/C})\,\pi\,(0.13\,\text{m})^2 \cos 0 = \boxed{31\,\text{N}\cdot\text{m}^2/\text{C}}$

(*b*) $\Phi_E = \vec{\mathbf{E}} \cdot \vec{\mathbf{A}} = EA\cos\theta = (580\,\text{N/C})\,\pi\,(0.13\,\text{m})^2 \cos 45° = \boxed{22\,\text{N}\cdot\text{m}^2/\text{C}}$

(*c*) $\Phi_E = \vec{\mathbf{E}} \cdot \vec{\mathbf{A}} = EA\cos\theta = (580\,\text{N/C})\,\pi\,(0.13\,\text{m})^2 \cos 90° = \boxed{0}$

2. Use Eq. 22-1b for the electric flux of a uniform field. Note that the surface area vector points radially outward, and the electric field vector points radially inward. Thus the angle between the two is 180°.

$$\Phi_E = \vec{\mathbf{E}} \cdot \vec{\mathbf{A}} = EA\cos\theta = (150\,\text{N/C})\,4\pi R_E^2 \cos 180° = -4\pi\,(150\,\text{N/C})\left(6.38\times10^6\,\text{m}\right)^2$$

$$= \boxed{-7.7\times10^{16}\,\text{N}\cdot\text{m}^2/\text{C}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

3. (*a*) Since the field is uniform, no lines originate or terminate inside the cube, and so the net flux is $\Phi_{\text{net}} = \boxed{0}$.

(*b*) There are two opposite faces with field lines perpendicular to the faces. The other four faces have field lines parallel to those faces. For the faces parallel to the field lines, no field lines enter or exit the faces. Thus $\Phi_{\text{parallel}} = \boxed{0}$.

Of the two faces that are perpendicular to the field lines, one will have field lines entering the cube, and so the angle between the field lines and the face area vector is 180°. The other will have field lines exiting the cube, and so the angle between the field lines and the face area vector is 0°. Thus we have $\Phi_{\text{entering}} = \vec{E}\bullet\vec{A} = E_0 A\cos 180° = \boxed{-E_0\ell^2}$ and $\Phi_{\text{leaving}} = \vec{E}\bullet\vec{A} = E_0 A\cos 0° = \boxed{E_0\ell^2}$.

4. (*a*) From the diagram in the textbook, we see that the flux outward through the hemispherical surface is the same as the flux inward through the circular surface base of the hemisphere. On that surface all of the flux is perpendicular to the surface. Or, we say that on the circular base, $\vec{\mathbf{E}} \parallel \vec{\mathbf{A}}$. Thus $\Phi_{\text{E}} = \vec{\mathbf{E}}\bullet\vec{\mathbf{A}} = \boxed{\pi r^2 E}$.

(b) $\vec{\mathbf{E}}$ is perpendicular to the axis, then every field line would both enter through the hemispherical surface and leave through the hemispherical surface, and so $\Phi_{\text{E}} = \boxed{0}$.

5. Use Gauss's law to determine the enclosed charge.

$$\Phi_{\text{E}} = \frac{Q_{\text{encl}}}{\varepsilon_o} \rightarrow Q_{\text{encl}} = \Phi_{\text{E}}\varepsilon_o = \left(1840\,\text{N}\cdot\text{m}^2/\text{C}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right) = \boxed{1.63\times10^{-8}\,\text{C}}$$

6. The net flux through each closed surface is determined by the net charge inside. Refer to the picture in the textbook.

$\Phi_1 = \left(+Q-3Q\right)/\varepsilon_0 = \boxed{-2Q/\varepsilon_0}$; $\Phi_2 = \left(+Q+2Q-3Q\right)/\varepsilon_0 = \boxed{0}$;

$\Phi_3 = \left(+2Q-3Q\right)/\varepsilon_0 = \boxed{-Q/\varepsilon_0}$; $\Phi_4 = \boxed{0}$; $\Phi_5 = \boxed{+2Q/\varepsilon_0}$

7. (*a*) Use Gauss's law to determine the electric flux.

$$\Phi_{\text{E}} = \frac{Q_{\text{encl}}}{\varepsilon_o} = \frac{-1.0\times10^{-6}\,\text{C}}{8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2} = \boxed{-1.1\times10^5\,\text{N}\cdot\text{m}^2/\text{C}}$$

(*b*) Since there is no charge enclosed by surface A_2, $\Phi_{\text{E}} = \boxed{0}$.

8. The net flux is only dependent on the charge enclosed by the surface. Since both surfaces enclose the same amount of charge, the flux through both surfaces is the same. Thus the ratio is $\boxed{1:1}$.

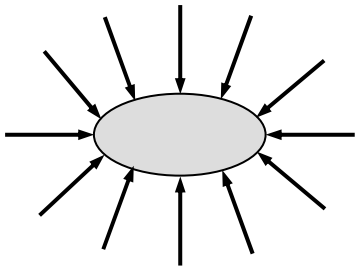
9. The only contributions to the flux are from the faces perpendicular to the electric field. Over each of these two surfaces, the magnitude of the field is constant, so the flux is just $\vec{\mathbf{E}}\bullet\vec{\mathbf{A}}$ on each of these two surfaces.

$$\Phi_{\text{E}} = \left(\vec{\mathbf{E}}\bullet\vec{\mathbf{A}}\right)_{\text{right}} + \left(\vec{\mathbf{E}}\bullet\vec{\mathbf{A}}\right)_{\text{left}} = E_{\text{right}}\ell^2 - E_{\text{left}}\ell^2 = \frac{Q_{\text{encl}}}{\varepsilon_0} \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$Q_{\text{encl}} = \left(E_{\text{right}} - E_{\text{left}}\right)\ell^2\varepsilon_0 = \left(410\,\text{N/C} - 560\,\text{N/C}\right)\left(25\,\text{m}\right)^2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right) = \boxed{-8.3\times10^{-7}\,\text{C}}$$

10. Because of the symmetry of the problem one sixth of the total flux will pass through each face.



$$\Phi_{\text{face}} = \tfrac{1}{6}\Phi_{\text{total}} = \tfrac{1}{6}\frac{Q_{\text{encl}}}{\varepsilon_0} = \boxed{\frac{Q_{\text{encl}}}{6\varepsilon_0}}$$

Notice that the side length of the cube did not enter into the calculation.

11. The charge density can be found from Eq. 22-4, Gauss's law. The charge is the charge density times the length of the rod.

$$\Phi = \frac{Q_{\text{encl}}}{\varepsilon_0} = \frac{\lambda\ell}{\varepsilon_0} = \quad\rightarrow\quad \lambda = \frac{\Phi\varepsilon_0}{\ell} = \frac{\left(7.3\times10^5\,\text{N}\cdot\text{m}^2/\text{C}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}{0.15\,\text{m}} = \boxed{4.3\times10^{-5}\,\text{C/m}}$$

12.

13. The electric field can be calculated by Eq. 21-4a, and that can be solved for the magnitude of the charge.

$$E = k\frac{Q}{r^2} \quad\rightarrow\quad Q = \frac{Er^2}{k} = \frac{\left(6.25\times10^2\,\text{N/C}\right)\left(3.50\times10^{-2}\,\text{m}\right)^2}{8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2} = 8.52\times10^{-11}\,\text{C}$$

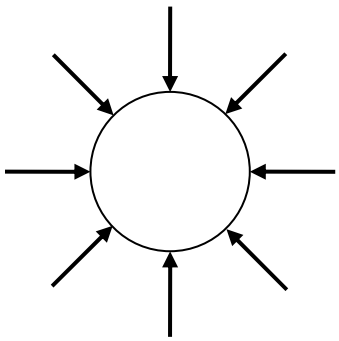
This corresponds to about 5×10^8 electrons. Since the field points toward the ball, the charge must be negative. Thus $Q = \boxed{-8.52\times10^{-11}\,\text{C}}$.

14. The charge on the spherical conductor is uniformly distributed over the surface area of the sphere, so $\sigma = \dfrac{Q}{4\pi R^2}$. The field at the surface of the sphere is evaluated at $r = R$.

$$E\left(r = R\right) = \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2} = \frac{1}{4\pi\varepsilon_0}\frac{4\pi R^2\sigma}{R^2} = \boxed{\frac{\sigma}{\varepsilon_0}}$$

15. The electric field due to a long thin wire is given in Example 22-6 as $E = \dfrac{1}{2\pi\varepsilon_0}\dfrac{\lambda}{R}$.

(*a*) $$E = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{R} = \frac{1}{4\pi\varepsilon_0}\frac{2\lambda}{R} = \left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{2\left(-7.2\times10^{-6}\,\text{C/m}\right)}{\left(5.0\,\text{m}\right)} = \boxed{-2.6\times10^4\,\text{N/C}}$$



The negative sign indicates the electric field is pointed towards the wire.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) $E = \dfrac{1}{2\pi\varepsilon_0}\dfrac{\lambda}{R} = \dfrac{1}{4\pi\varepsilon_0}\dfrac{2\lambda}{R} = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\dfrac{2\left(-7.2\times10^{-6}\ \text{C/m}\right)}{(1.5\,\text{m})} = \boxed{-8.6\times10^4\ \text{N/C}}$

The negative sign indicates the electric field is pointed towards the wire.

16. Because the globe is a conductor, the net charge of -1.50 mC will be arranged symmetrically around the sphere.

17. Due to the spherical symmetry of the problem, the electric field can be evaluated using Gauss's law and the charge enclosed by a spherical Gaussian surface of radius *r*.

$$\oint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad\rightarrow\quad E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2}$$

Since the charge densities are constant, the charge enclosed is found by multiplying the appropriate charge density times the volume of charge enclosed by the Gaussian sphere. Let $r_1 = 6.0\,\text{cm}$ and $r_2 = 12.0\,\text{cm}$.

(*a*) Negative charge is enclosed for $r < r_1$.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{\rho_{(-)}\left(\frac{4}{3}\pi r^3\right)}{r^2} = \frac{\rho_{(-)}r}{3\varepsilon_0} = \frac{\left(-5.0\,\text{C/m}^3\right)r}{3\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}$$

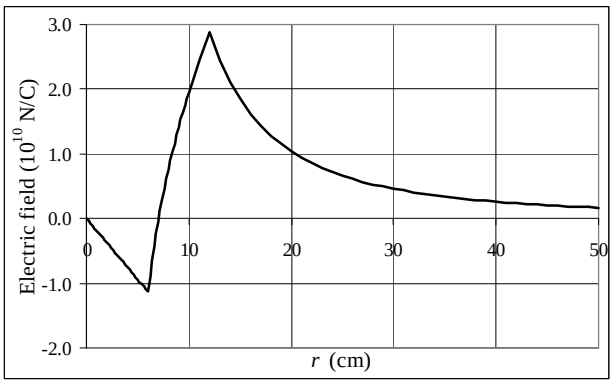
$$= \boxed{\left(-1.9\times10^{11}\ \text{N/C}\bullet\text{m}\right)r}$$

(*b*) In the region $r_1 < r < r_2$, all of the negative charge and part of the positive charge is enclosed.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{\rho_{(-)}\left(\frac{4}{3}\pi r_1^3\right)+\rho_{(+)}\left[\frac{4}{3}\pi\left(r^3-r_1^3\right)\right]}{r^2} = \frac{\left(\rho_{(-)}-\rho_{(+)}\right)\left(r_1^3\right)}{3\varepsilon_0 r^2} + \frac{\rho_{(+)}r}{3\varepsilon_0}$$

$$= \frac{\left[\left(-5.0\,\text{C/m}^3\right)-\left(8.0\,\text{C/m}^3\right)\right](0.060\,\text{m})^3}{3\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)r^2} + \frac{\left(8.0\,\text{C/m}^3\right)r}{3\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}$$

$$= \boxed{\frac{\left(-1.1\times10^8\ \text{N}\bullet\text{m}^2/\text{C}\right)}{r^2} + \left(3.0\times10^{11}\ \text{N/C}\bullet\text{m}\right)r}$$



(*c*) In the region $r_2 < r$, all of the charge is enclosed.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{\rho_{(-)}\left(\frac{4}{3}\pi r_1^3\right)+\rho_{(+)}\left[\frac{4}{3}\pi\left(r_2^3-r_1^3\right)\right]}{r^2} = \frac{\left(\rho_{(-)}-\rho_{(+)}\right)\left(r_1^3\right)+\rho_{(+)}\left(r_2^3\right)}{3\varepsilon_0 r^2} =$$

$$= \frac{\left[\left(-5.0\,\text{C/m}^3\right)-\left(8.0\,\text{C/m}^3\right)\right](0.060\,\text{m})^3+\left(8.0\,\text{C/m}^3\right)(0.120\text{m})^3}{3\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)r^2} = \boxed{\frac{\left(4.1\times10^8\ \text{N}\bullet\text{m}^2/\text{C}\right)}{r^2}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*d*) See the adjacent plot. The field is continuous at the edges of the layers. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH22.XLS," on tab "Problem 22.17d."

18. See Example 22-3 for a detailed discussion related to this problem.
(*a*) Inside a solid metal sphere the electric field is $\boxed{0}$.
(*b*) Inside a solid metal sphere the electric field is $\boxed{0}$.
(*c*) Outside a solid metal sphere the electric field is the same as if all the charge were concentrated at the center as a point charge.

$$|E| = \frac{1}{4\pi\varepsilon_0}\frac{|Q|}{r^2} = \left(8.988\times10^9\ \mathrm{N\cdot m^2/C^2}\right)\frac{\left(5.50\times10^{-6}\mathrm{C}\right)}{\left(3.10\,\mathrm{m}\right)^2} = \boxed{5140\,\mathrm{N/C}}$$

The field would point towards the center of the sphere.
(*d*) Same reasoning as in part (*c*).

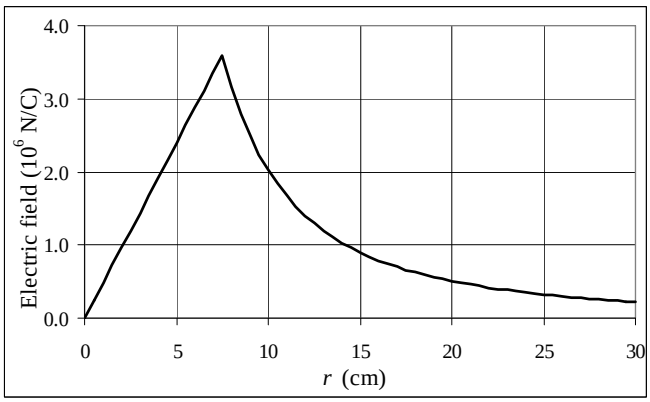
$$|E| = \frac{1}{4\pi\varepsilon_0}\frac{|Q|}{r^2} = \left(8.988\times10^9\ \mathrm{N\cdot m^2/C^2}\right)\frac{\left(5.50\times10^{-6}\mathrm{C}\right)}{\left(8.00\,\mathrm{m}\right)^2} = \boxed{772\,\mathrm{N/C}}$$

The field would point towards the center of the sphere.
(*e*) The answers would be $\boxed{\text{no different}}$ for a thin metal shell.
(*f*) The solid sphere of charge is dealt with in Example 22-4. We see from that Example that the field inside the sphere is given by $|E| = \frac{1}{4\pi\varepsilon_0}\frac{|Q|}{r_0^3}r$. Outside the sphere the field is no different.

So we have these results for the solid sphere.

$$|E(r=0.250\,\mathrm{m})| = \left(8.988\times10^9\ \mathrm{N\cdot m^2/C^2}\right)\frac{5.50\times10^{-6}\mathrm{C}}{\left(3.00\,\mathrm{m}\right)^3}\left(0.250\,\mathrm{m}\right) = \boxed{458\,\mathrm{N/C}}$$

$$|E(r=2.90\,\mathrm{m})| = \left(8.988\times10^9\ \mathrm{N\cdot m^2/C^2}\right)\frac{5.50\times10^{-6}\mathrm{C}}{\left(3.00\,\mathrm{m}\right)^3}\left(2.90\,\mathrm{m}\right) = \boxed{5310\,\mathrm{N/C}}$$



$$|E(r=3.10\,\mathrm{m})| = \left(8.988\times10^9\ \mathrm{N\cdot m^2/C^2}\right)\frac{5.50\times10^{-6}\mathrm{C}}{\left(3.10\,\mathrm{m}\right)^2} = \boxed{5140\,\mathrm{N/C}}$$

$$|E(r=8.00\,\mathrm{m})| = \left(8.988\times10^9\ \mathrm{N\cdot m^2/C^2}\right)\frac{5.50\times10^{-6}\mathrm{C}}{\left(3.10\,\mathrm{m}\right)^2} = \boxed{772\,\mathrm{N/C}}$$

All point towards the center of the sphere.

19. For points inside the nonconducting spheres, the electric field will be determined by the charge inside the spherical surface of radius *r*.

$$Q_{\text{encl}} = Q\left(\frac{\frac{4}{3}\pi r^3}{\frac{4}{3}\pi r_0^3}\right) = Q\left(\frac{r}{r_0}\right)^3$$

The electric field for $r \le r_0$ can be calculated from Gauss's law.

$$E(r \le r_0) = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2}$$

$$= Q\left(\frac{r}{r_0}\right)^3 \frac{1}{4\pi\varepsilon_0 r^2} = \left(\frac{Q}{4\pi\varepsilon_0 r_0^3}\right) r$$

The electric field outside the sphere is calculated from Gauss's law with $Q_{\text{encl}} = Q$.

$$E\left(r \ge r_0\right) = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \frac{Q}{4\pi\varepsilon_0 r^2}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH22.XLS," on tab "Problem 22.19."

20. (*a*) When close to the sheet, we approximate it as an infinite sheet, and use the result of Example 22-7. We assume the charge is over both surfaces of the aluminum.

$$E = \frac{\sigma}{2\varepsilon_o} = \frac{\dfrac{275\times10^{-9}\,\text{C}}{\left(0.25\,\text{m}\right)^2}}{2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = \boxed{2.5\times10^5\,\text{N/C, away from the sheet}}$$

(*b*) When far from the sheet, we approximate it as a point charge.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2} = \left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{275\times10^{-9}\,\text{C}}{\left(15\,\text{m}\right)^2} = \boxed{11\,\text{N/C, away from the sheet}}$$

21. (*a*) Consider a spherical gaussian surface at a radius of 3.00 cm. It encloses all of the charge.

$$\oint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q}{\varepsilon_0} \quad \rightarrow$$

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2} = \left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{5.50\times10^{-6}\,\text{C}}{\left(3.00\times10^{-2}\,\text{m}\right)^2} = \boxed{5.49\times10^7\,\text{N/C, radially outward}}$$

(*b*) A radius of 6.00 cm is inside the conducting material, and so the field must be **0**. Note that there must be an induced charge of $-5.50\times10^{-6}\,\text{C}$ on the surface at r = 4.50 cm, and then an induced charge of $5.50\times10^{-6}\,\text{C}$ on the outer surface of the sphere.

(*c*) Consider a spherical gaussian surface at a radius of 3.00 cm. It encloses all of the charge.

$$\oint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q}{\varepsilon_0} \quad \rightarrow$$

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2} = \left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{5.50\times10^{-6}\,\text{C}}{\left(30.0\times10^{-2}\,\text{m}\right)^2} = \boxed{5.49\times10^5\,\text{N/C, radially outward}}$$

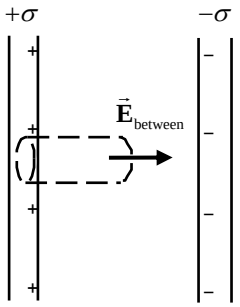
22. (*a*) Inside the shell, the field is that of the point charge, $\boxed{E = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2}}$.

(*b*) There is no field inside the conducting material: $\boxed{E = 0}$.

(*c*) Outside the shell, the field is that of the point charge, $\boxed{E = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2}}$.



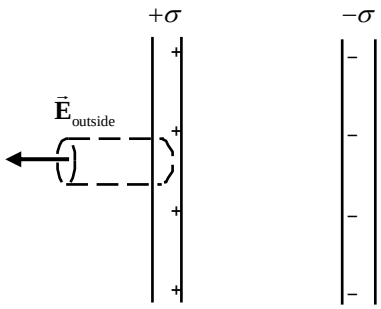
(*d*) The shell does not affect the field due to *Q* alone, except in the shell material, where the field is 0. The charge *Q* does affect the shell – it polarizes it. There will be an induced charge of $-Q$ uniformly distributed over the inside surface of the shell, and an induced charge of $+Q$ uniformly distributed over the outside surface of the shell.

23. (*a*) There can be no field inside the conductor, and so there must be an induced charge of $\boxed{-8.00\,\mu\text{C}}$ on the surface of the spherical cavity.

(*b*) Any charge on the conducting material must reside on its boundaries. If the net charge of the cube is $-6.10\,\mu\text{C}$, and there is a charge of $-8.00\,\mu\text{C}$ on its inner surface, there must be a charge of $\boxed{+1.90\,\mu\text{C}}$ on the outer surface.

24. Since the charges are of opposite sign, and since the charges are free to move since they are on conductors, the charges will attract each other and move to the inside or facing edges of the plates. There will be no charge on the outside edges of the plates. And there cannot be charge in the plates themselves, since they are conductors. All of the charge must reside on surfaces. Due to the symmetry of the problem, all field lines must be perpendicular to the plates, as discussed in Example 22-7.

(*a*) To find the field between the plates, we choose a gaussian cylinder, perpendicular to the plates, with area A for the ends of the cylinder. We place one end inside the left plate (where the field must be zero), and the other end between the plates. No flux passes through the curved surface of the cylinder.

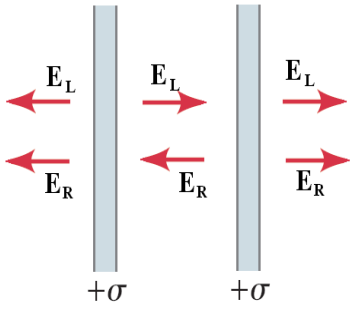


$$\oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} + \int_{\text{side}} \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = \int_{\substack{\text{right}\\ \text{end}}} \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow$$

$$E_{\text{between}}A = \frac{\sigma A}{\varepsilon_0} \quad \rightarrow \quad \boxed{E_{\text{between}} = \frac{\sigma}{\varepsilon_0}}$$

The field lines between the plates leave the inside surface of the left plate, and terminate on the inside surface of the right plate. A similar derivation could have been done with the right end of the cylinder inside of the right plate, and the left end of the cylinder in the space between the plates.

(*b*) If we now put the cylinder from above so that the right end is inside the conducting material, and the left end is to the left of the left plate, the only possible location for flux is through the left end of the cylinder. Note that there is NO charge enclosed by the Gaussian cylinder.



$$\oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} + \int_{\text{side}} \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = \int_{\substack{\text{left}\\ \text{end}}} \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E_{\text{outside}}A = \frac{0}{\varepsilon_0} \quad \rightarrow \quad \boxed{E_{\text{outside}} = \frac{0}{\varepsilon_0}}$$

(*c*) If the two plates were nonconductors, the results would not change. The charge would be distributed over the two plates in a different fashion, and the field inside of the plates would not be zero, but the charge in the empty regions of space would be the same as when the plates are conductors.

25. Example 22-7 gives the electric field from a positively charged plate as $E = \sigma / 2\varepsilon_0$ with the field pointing away from the plate. The fields from the two plates will add, as shown in the figure.

(*a*) Between the plates the fields are equal in magnitude, but point in opposite directions.

$$E_{\text{between}} = \frac{\sigma}{2\varepsilon_0} - \frac{\sigma}{2\varepsilon_0} = \boxed{0}$$

(*b*) Outside the two plates the fields are equal in magnitude and point in the same direction.

$$E_{\text{outside}} = \frac{\sigma}{2\varepsilon_0} + \frac{\sigma}{2\varepsilon_0} = \boxed{\frac{\sigma}{\varepsilon_0}}$$

(*c*) When the plates are conducting the charge lies on the surface of the plates. For nonconducting plates the same charge will be spread across the plate. This will not affect the electric field between or outside the two plates. It will, however, allow for a non-zero field inside each plate.

26. Because 3.0 cm << 1.0 m, we can consider the plates to be infinite in size, and ignore any edge effects. We use the result from Problem 24(*a*).

$$E = \frac{\sigma}{\varepsilon_0} = \frac{Q/A}{\varepsilon_0} \quad \rightarrow \quad Q = EA\varepsilon_0 = (160\,\text{N/C})(1.0\,\text{m})^2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right) = \boxed{1.4\times10^{-9}\,\text{C}}$$

27. (*a*) In the region $0 < r < r_1$, a gaussian surface would enclose no charge. Thus, due to the spherical symmetry, we have the following.

$$\oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} = 0 \quad \rightarrow \quad E = \boxed{0}$$

(*b*) In the region $r_1 < r < r_2$, only the charge on the inner shell will be enclosed.

$$\oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} = \frac{\sigma_1 4\pi r_1^2}{\varepsilon_0} \quad \rightarrow \quad E = \boxed{\frac{\sigma_1 r_1^2}{\varepsilon_0 r^2}}$$

(*c*) In the region $r_2 < r$, the charge on both shells will be enclosed.

$$\oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} = \frac{\sigma_1 4\pi r_1^2 + \sigma_2 4\pi r_2^2}{\varepsilon_0} \quad \rightarrow \quad E = \boxed{\frac{\sigma_1 r_1^2 + \sigma_2 r_2^2}{\varepsilon_0 r^2}}$$

(*d*) To make $E = 0$ for $r_2 < r$, we must have $\boxed{\sigma_1 r_1^2 + \sigma_2 r_2^2 = 0}$. This implies that the shells are of opposite charge.

(*e*) To make $E = 0$ for $r_1 < r < r_2$, we must have $\boxed{\sigma_1 = 0}$. Or, if a charge $Q = -4\pi\sigma_1 r_1^2$ were placed at the center of the shells, that would also make $E = 0$.

28. If the radius is to increase from r_0 to $2r_0$ linearly during an elapsed time of *T*, then the rate of increase must be r_0/T. The radius as a function of time is then $r = r_0 + \frac{r_0}{T}t = r_0\left(1+\frac{t}{T}\right)$. Since the balloon is spherical, the field outside the balloon will have the same form as the field due to a point charge.

(*a*) Here is the field just outside the balloon surface.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2} = \boxed{\frac{1}{4\pi\varepsilon_0}\frac{Q}{r_0^2\left(1+\frac{t}{T}\right)^2}}$$

(*b*) Since the balloon radius is always smaller than $3.2r_0$, the total charge enclosed in a gaussian surface at $r = 3.2r_0$ does not change in time.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2} = \boxed{\frac{1}{4\pi\varepsilon_0}\frac{Q}{\left(3.2r_0\right)^2}}$$

29. Due to the spherical symmetry of the problem, Gauss's law using a sphere of radius *r* leads to the following.

$$\oint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2}$$

(*a*) For the region $0 < r < r_1$, the enclosed charge is 0.

$$E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \boxed{0}$$

(*b*) For the region $r_1 < r < r_0$, the enclosed charge is the product of the volume charge density times the volume of charged material enclosed. The charge density is given by $\rho = \frac{Q}{\frac{4}{3}\pi r_0^3 - \frac{4}{3}\pi r_1^3}$

$$= \frac{3Q}{4\pi\left(r_0^3 - r_1^3\right)}.$$

$$E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \frac{\rho V_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \frac{\rho\left[\frac{4}{3}\pi r^3 - \frac{4}{3}\pi r_1^3\right]}{4\pi\varepsilon_0 r^2} = \frac{\frac{3Q}{4\pi\left(r_0^3 - r_1^3\right)}\left[\frac{4}{3}\pi r^3 - \frac{4}{3}\pi r_1^3\right]}{4\pi\varepsilon_0 r^2} = \boxed{\frac{Q}{4\pi\varepsilon_0 r^2}\frac{\left(r^3 - r_1^3\right)}{\left(r_0^3 - r_1^3\right)}}$$

(*c*) For the region $r > r_0$, the enclosed charge is the total charge, *Q*.

$$E = \frac{Q}{4\pi\varepsilon_0 r^2}$$

30. By the superposition principle for electric fields (Section 21-6), we find the field for this problem by adding the field due to the point charge at the center to the field found in Problem 29. At any location $r > 0$, the field due to the point charge is $E = \frac{q}{4\pi\varepsilon_0 r^2}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*a*) $E = E_q + E_Q = \dfrac{q}{4\pi\varepsilon_0 r^2} + 0 = \boxed{\dfrac{q}{4\pi\varepsilon_0 r^2}}$

(*b*) $E = E_q + E_Q = \dfrac{q}{4\pi\varepsilon_0 r^2} + \dfrac{Q}{4\pi\varepsilon_0 r^2}\dfrac{\left(r^3 - r_1^3\right)}{\left(r_0^3 - r_1^3\right)} = \boxed{\dfrac{1}{4\pi\varepsilon_0 r^2}\left[q + Q\dfrac{\left(r^3 - r_1^3\right)}{\left(r_0^3 - r_1^3\right)}\right]}$

(*c*) $E = E_q + E_Q = \dfrac{q}{4\pi\varepsilon_0 r^2} + \dfrac{Q}{4\pi\varepsilon_0 r^2} = \boxed{\dfrac{q+Q}{4\pi\varepsilon_0 r^2}}$

31. (*a*) Create a gaussian surface that just encloses the inner surface of the spherical shell. Since the electric field inside a conductor must be zero, Gauss's law requires that the enclosed charge be zero. The enclosed charge is the sum of the charge at the center and charge on the inner surface of the conductor.

$$Q_{\text{enc}} = q + Q_{\text{inner}} = 0$$

Therefore $Q_{\text{inner}} = \boxed{-q}$.

(*b*) The total charge on the conductor is the sum of the charges on the inner and outer surfaces.

$$Q = Q_{\text{outer}} + Q_{\text{inner}} \quad \rightarrow \quad Q_{\text{outer}} = Q - Q_{\text{inner}} = \boxed{Q + q}$$

(*c*) A gaussian surface of radius $r < r_1$ only encloses the center charge, *q*. The electric field will therefore be the field of the single charge.

$$\boxed{E(r < r_1) = \frac{q}{4\pi\varepsilon_0 r^2}}$$

(*d*) A gaussian surface of radius $r_1 < r < r_0$ is inside the conductor so $\boxed{E = 0}$.

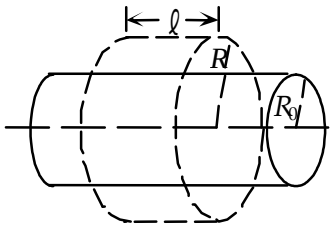
(*e*) A gaussian surface of radius $r > r_0$ encloses the total charge $q + Q$. The electric field will then be the field from the sum of the two charges.

$$\boxed{E(r > r_0) = \frac{q+Q}{4\pi\varepsilon_0 r^2}}$$

32. (*a*) For points inside the shell, the field will be due to the point charge only.

$$E\left(r < r_0\right) = \boxed{\frac{q}{4\pi\varepsilon_0 r^2}}$$

(*b*) For points outside the shell, the field will be that of a point charge, equal to the total charge.



$$E\left(r > r_0\right) = \boxed{\frac{q+Q}{4\pi\varepsilon_0 r^2}}$$

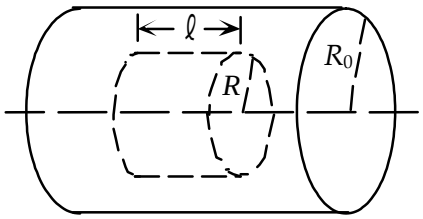
(*c*) If $q = Q$, we have $E\left(r < r_0\right) = \boxed{\dfrac{Q}{4\pi\varepsilon_0 r^2}}$ and $E\left(r > r_0\right) = \boxed{\dfrac{2Q}{4\pi\varepsilon_0 r^2}}$.

(*d*) If $q = -Q$, we have $E\left(r < r_0\right) = \boxed{\dfrac{-Q}{4\pi\varepsilon_0 r^2}}$ and $E\left(r > r_0\right) = \boxed{0}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

33. We follow the development of Example 22-6. Because of the symmetry, we expect the field to be directed radially outward (no fringing effects near the ends of the cylinder) and to depend only on the perpendicular distance, R, from the symmetry axis of the shell. Because of the cylindrical symmetry, the field will be the same at all points on a gaussian surface that is a cylinder whose axis coincides with the axis of the shell. The gaussian surface is of radius r and length ℓ. $\vec{\mathbf{E}}$ is perpendicular to this surface at all points. In order to apply Gauss's law, we need a closed surface, so we include the flat ends of the cylinder. Since $\vec{\mathbf{E}}$ is parallel to the flat ends, there is no flux through the ends. There is only flux through the curved wall of the gaussian cylinder.

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E\left(2\pi R\ell\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} = \frac{\sigma A_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{\sigma A_{\text{encl}}}{2\pi\varepsilon_0 R\ell}$$



(*a*) For $R > R_0$, the enclosed surface area of the shell is $A_{\text{encl}} = 2\pi R_0 \ell$.

$$E = \frac{\sigma A_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{\sigma 2\pi R_0 \ell}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\sigma R_0}{\varepsilon_0 R}, \text{ radially outward}}$$

(*b*) For $R < R_0$, the enclosed surface area of the shell is $A_{\text{encl}} = 0$, and so $E = \boxed{0}$.

(*c*) The field for $R > R_0$ due to the shell is the same as the field due to the long line of charge, if we substitute $\boxed{\lambda = 2\pi R_0 \sigma}$.

34. The geometry of this problem is similar to Problem 33, and so we use the same development, following Example 22-6. See the solution of Problem 33 for details.

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E\left(2\pi R\ell\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} = \frac{\rho_{\text{E}} V_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{\rho_{\text{E}} V_{\text{encl}}}{2\pi\varepsilon_0 R\ell}$$

(*a*) For $R > R_0$, the enclosed volume of the shell is $V_{\text{encl}} = \pi R_0^2 \ell$.

$$E = \frac{\rho_{\text{E}} V_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\rho_{\text{E}} R_0^2}{2\varepsilon_0 R}, \text{ radially outward}}$$

(*b*) For $R < R_0$, the enclosed volume of the shell is $V_{\text{encl}} = \pi R^2 \ell$.

$$E = \frac{\rho_{\text{E}} V_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\rho_{\text{E}} R}{2\varepsilon_0}, \text{ radially outward}}$$

35. The geometry of this problem is similar to Problem 33, and so we use the same development, following Example 22-6. See the solution of Problem 33 for details. We choose the gaussian cylinder to be the same length as the cylindrical shells.

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E\left(2\pi R\ell\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell}$$

(*a*) For $0 < R < R_1$, no charge is enclosed, and so $E = \dfrac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \boxed{0}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) For $R_1 < R < R_2$, charge $+Q$ is enclosed, and so $E = \boxed{\dfrac{Q}{2\pi\varepsilon_0 R\ell}, \text{ radially outward}}$.

(*c*) For $R > R_2$, both charges of $+Q$ and $-Q$ are enclosed, and so $E = \dfrac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \boxed{0}$.

(*d*) The force on an electron between the cylinders points in the direction opposite to the electric field, and so the force is inward. The electric force produces the centripetal acceleration for the electron to move in the circular orbit.

$$F_{\text{centrip}} = eE = \frac{eQ}{2\pi\varepsilon_0 R\ell} = m\frac{v^2}{R} \quad \rightarrow \quad K = \tfrac{1}{2}mv^2 = \boxed{\frac{eQ}{4\pi\varepsilon_0 \ell}}$$

Note that this is independent of the actual value of the radius, as long as $R_1 < R < R_2$.

36. The geometry of this problem is similar to Problem 33, and so we use the same development, following Example 22-6. See the solution of Problem 33 for details. We choose the gaussian cylinder to be the same length as the cylindrical shells.

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E\left(2\pi R\ell\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell}$$

(*a*) At a distance of $R = 3.0\,\text{cm}$, no charge is enclosed, and so $E = \dfrac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \boxed{0}$.

(*b*) At a distance of $R = 7.0\,\text{cm}$, the charge on the inner cylinder is enclosed.

$$E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{2}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{R\ell} = 2\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(-0.88\times10^{-6}\,\text{C}\right)}{\left(0.070\,\text{m}\right)\left(5.0\,\text{m}\right)} = \boxed{-4.5\times10^4\ \text{N/C}}$$

The negative sign indicates that the field points radially inward.

(*c*) At a distance of $R = 12.0\,\text{cm}$, the charge on both cylinders is enclosed.

$$E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{2}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{R\ell} = 2\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(1.56-0.88\right)\times10^{-6}\,\text{C}}{\left(0.120\,\text{m}\right)\left(5.0\,\text{m}\right)} = \boxed{2.0\times10^4\ \text{N/C}}$$

The field points radially outward.

37. (*a*) The final speed can be calculated from the work-energy theorem, where the work is the integral of the force on the electron between the two shells.

$$W = \int \vec{F} \cdot d\vec{r} = \tfrac{1}{2}mv^2 - \tfrac{1}{2}mv_0^2$$

Setting the force equal to the electric field times the charge on the electron, and inserting the electric field from Problem 36 gives the work done on the electron.

$$W = \int_{R_1}^{R_2} \frac{qQ}{2\pi\varepsilon_0 \ell R}\,dR = \frac{qQ}{2\pi\varepsilon_0 \ell}\ln\left(\frac{R_2}{R_1}\right)$$

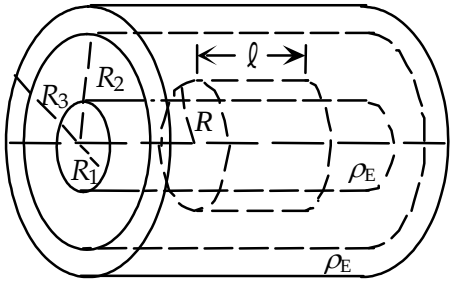
$$= \frac{\left(-1.60\times10^{-19}\,\text{C}\right)\left(-0.88\mu\text{C}\right)}{2\pi\left(8.85\times10^{-12}\,\text{C}^2/\text{Nm}^2\right)\left(5.0\,\text{m}\right)}\ln\left(\frac{9.0\,\text{cm}}{6.5\,\text{cm}}\right) = 1.65\times10^{-16}\ \text{J}$$

Solve for the velocity from the work-energy theorem.

$$v = \sqrt{\frac{2W}{m}} = \sqrt{\frac{2\left(1.65\times10^{-16}\ \text{J}\right)}{9.1\times10^{-31}\ \text{kg}}} = \boxed{1.9\times10^7\ \text{m/s}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The electric force on the proton provides its centripetal acceleration.



$$F_c = \frac{mv^2}{R} = qE = \frac{|qQ|}{2\pi\varepsilon_0 \ell R}$$

The velocity can be solved for from the centripetal acceleration.

$$v = \sqrt{\frac{\left(1.60\times10^{-19}\text{C}\right)\left(0.88\mu\text{C}\right)}{2\pi\left(8.85\times10^{-12}\text{C}^2/\text{Nm}^2\right)\left(1.67\times10^{-27}\text{kg}\right)\left(5.0\text{ m}\right)}} = \boxed{5.5\times10^5\text{m/s}}$$

Note that as long as the proton is between the two cylinders, the velocity is independent of the radius.

38. The geometry of this problem is similar to Problem 33, and so we use the same development, following Example 22-6. See the solution of Problem 33 for details.

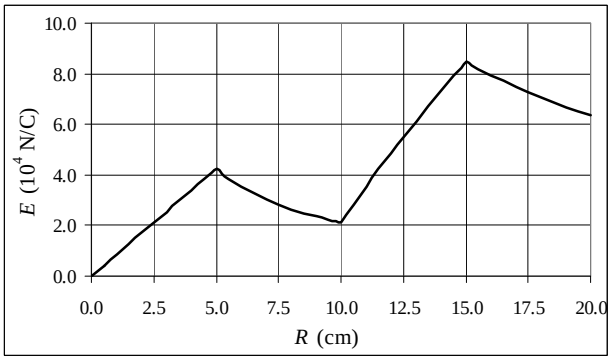
$$\oint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = E\left(2\pi R\ell\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell}$$

(*a*) For $0 < R < R_1$, the enclosed charge is the volume of charge enclosed, times the charge density.

$$E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{\rho_E \pi R^2 \ell}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\rho_E R}{2\varepsilon_0}}$$

(*b*) For $R_1 < R < R_2$, the enclosed charge is all of the charge on the inner cylinder.

$$E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{\rho_E \pi R_1^2 \ell}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\rho_E R_1^2}{2\varepsilon_0 R}}$$



(*c*) For $R_2 < R < R_3$, the enclosed charge is all of the charge on the inner cylinder, and the part of the charge on the shell that is enclosed by the gaussian cylinder.

$$E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{\rho_E \pi R_1^2 \ell + \rho_E\left(\pi R^2\ell - \pi R_2^2\ell\right)}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\rho_E\left(R_1^2 + R^2 - R_2^2\right)}{2\varepsilon_0 R}}$$

(*d*) For $R > R_3$, the enclosed charge is all of the charge on both the inner cylinder and the shell.

$$E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{\rho_E \pi R_1^2 \ell + \rho_E\left(\pi R_3^2\ell - \pi R_2^2\ell\right)}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\rho_E\left(R_1^2 + R_3^2 - R_2^2\right)}{2\varepsilon_0 R}}$$

(*e*) See the graph. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH22.XLS," on tab "Problem 22.38e."

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

39. Due to the spherical symmetry of the geometry, we have the following to find the electric field at any radius *r*. The field will point either radially out or radially in.

$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2}$$

(*a*) For $0 < r < r_0$, the enclosed charge is due to the part of the charged sphere that has a radius smaller than *r*.

$$E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \frac{\rho_{\text{E}}\left(\frac{4}{3}\pi r^3\right)}{4\pi\varepsilon_0 r^2} = \boxed{\frac{\rho_{\text{E}} r}{3\varepsilon_0}}$$

(*b*) For $r_0 < r < r_1$, the enclosed charge is due to the entire charged sphere of radius r_0.

$$E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \frac{\rho_{\text{E}}\left(\frac{4}{3}\pi r_0^3\right)}{4\pi\varepsilon_0 r^2} = \boxed{\frac{\rho_{\text{E}} r_0^3}{3\varepsilon_0 r^2}}$$

(*c*) For $r_1 < r < r_2$, *r* is in the interior of the conducting spherical shell, and so $E = \boxed{0}$. This implies that $Q_{\text{encl}} = 0$, and so there must be an induced charge of magnitude $-\frac{4}{3}\rho_{\text{E}}\pi r_0^3$ on the inner surface of the conducting shell, at r_1.

(*d*) For $r > r_2$, the enclosed charge is the total charge of both the sphere and the shell.

$$E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \frac{Q + \rho_{\text{E}}\left(\frac{4}{3}\pi r_0^3\right)}{4\pi\varepsilon_0 r^2} = \boxed{\left(\frac{Q}{4\pi\varepsilon_0} + \frac{\rho_{\text{E}} r_0^3}{3\varepsilon_0}\right)\frac{1}{r^2}}$$

40. The conducting outer tube is uncharged, and the electric field is 0 everywhere within the conducting material. Because there will be no electric field inside the conducting material of the outer cylinder tube, the charge on the inner nonconducting cylinder will induce an oppositely signed, equal magnitude charge on the inner surface of the conducting tube. This charge will NOT be uniformly distributed, because the inner cylinder is not in the center of the tube. Since the conducting tube has no net charge, there will be an induced charge on the OUTER surface of the conducting tube, equal in magnitude to the charge on the inner cylinder, and of the same sign. This charge will be uniformly distributed. Since there is no electric field in the conducting material of the tube, there is no way for the charges in the region interior to the tube to influence the charge distribution on the outer surface. Thus the field outside the tube is due to a cylindrically symmetric distribution of charge. Application of Gauss's law as in Example 22-6, for a Gaussian cylinder with a radius larger than the conducting tube, and a length ℓ leads to $E\left(2\pi R\ell\right) = \frac{Q_{\text{encl}}}{\varepsilon_0}$. The enclosed charge is the amount of charge on the inner cylinder.

$$Q_{\text{encl}} = \rho_{\text{E}}\pi R_1^2\ell \quad \rightarrow \quad E = \frac{Q_{\text{encl}}}{\varepsilon_0\left(2\pi R\ell\right)} = \boxed{\frac{\rho_{\text{E}} R_1^2}{2\varepsilon_0 R}}$$

41. We treat the source charge as a disk of positive charge of radius concentric with a disk of negative charge of radius R_0. In order for the net charge of the inner space to be 0, the charge per unit area of the source disks must both have the same magnitude but opposite sign. The field due to the annulus is then the sum of the fields due to both the positive and negative rings.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*a*) At a distance of $0.25R_0$ from the center of the ring, we can approximate both of the disks as infinite planes, each producing a uniform field. Since those two uniform fields will be of the same magnitude and opposite sign, the net field is $\boxed{0}$.

(*b*) At a distance of $75R_0$ from the center of the ring, it appears to be approximately a point charge, and so the field will approximate that of a point charge, $E = \boxed{\dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{(75R_0)^2}}$

42. The conducting sphere is uncharged, and the electric field is 0 everywhere within its interior, except for in the cavities. When charge Q_1 is placed in the first cavity, a charge $-Q_1$ will be drawn from the conducting material to the inner surface of the cavity, and the electric field will remain 0 in the conductor. That charge $-Q_1$ will NOT be distributed symmetrically on the cavity surface. Since the conductor is neutral, a compensating charge Q_1 will appear on the outer surface of the conductor (charge can only be on the surfaces of conductors in electrostatics). Likewise, when charge Q_2 is placed in the second cavity, a charge $-Q_2$ will be drawn from the conducting material, and a compensating charge Q_2 will appear on the outer surface. Since there is no electric field in the conducting material, there is no way for the charges in the cavities to influence the charge distribution on the outer surface. So the distribution of charge on the outer surface is uniform, just as it would be if there were no inner charges, and instead a charge $Q_1 + Q_2$ were simply placed on the conductor. Thus the field outside the conductor is due to a spherically symmetric distribution of $Q_1 + Q_2$. Application of Gauss's law leads to $E = \boxed{\dfrac{1}{4\pi\varepsilon_0}\dfrac{Q_1+Q_2}{r^2}}$. If $Q_1 + Q_2 > 0,$ the field will point radially outward. If $Q_1 + Q_2 < 0,$ the field will point radially inward.

43. (*a*) Choose a cylindrical gaussian surface with the flat ends parallel to and equidistant from the slab. By symmetry the electric field must point perpendicularly away from the slab, resulting in no flux passing through the curved part of the gaussian cylinder. By symmetry the flux through each end of the cylinder must be equal with the electric field constant across the surface. $\oint \vec{E}\cdot d\vec{A} = 2EA$

The charge enclosed by the surface is the charge density of the slab multiplied by the volume of the slab enclosed by the surface.

$$q_{enc} = \rho_E (Ad)$$

Gauss's law can then be solved for the electric field.

$$\oint \vec{E}\cdot d\vec{A} = 2EA = \frac{\rho_E Ad}{\varepsilon_0} \quad \rightarrow \quad E = \boxed{\frac{\rho_E d}{2\varepsilon_0}}$$

Note that this electric field is independent of the distance from the slab.

(*b*) When the coordinate system of this problem is changed to axes parallel $(\hat{\mathbf{z}})$ and perpendicular $(\hat{\mathbf{r}})$ to the slab, it can easily be seen that the particle will hit the slab if the initial perpendicular velocity is sufficient for the particle to reach the slab before the acceleration decreases its velocity to zero. In the new coordinate system the axes are rotated by 45°.

$$\vec{r}_0 = y_0\cos 45°\hat{\mathbf{r}} + y_0\sin 45°\hat{\mathbf{z}} = \frac{y_0}{\sqrt{2}}\hat{\mathbf{r}} + \frac{y_0}{\sqrt{2}}\hat{\mathbf{z}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\vec{v}_0 = -v_0 \sin 45°\hat{\mathbf{r}} + v_0 \cos 45°\hat{\mathbf{z}} = -\frac{v_0}{\sqrt{2}}\hat{\mathbf{r}} + \frac{v_0}{\sqrt{2}}\hat{\mathbf{z}}$$

$$\vec{a} = qE/m\hat{\mathbf{r}}$$

The perpendicular components are then inserted into Eq. 2-12c, with the final velocity equal to zero.

$$0 = v_{r0}^2 - 2a(r - r_0) = \frac{v_0^2}{2} - 2\frac{q}{m}\left(\frac{\rho_E d}{2\varepsilon_0}\right)\left(\frac{y_0}{\sqrt{2}} - 0\right)$$

Solving for the velocity gives the minimum speed that the particle can have to reach the slab.

$$v_0 \geq \boxed{\sqrt{\frac{\sqrt{2}q\rho_E dy_0}{m\varepsilon_0}}}$$

44. Due to the spherical symmetry of the problem, Gauss's law using a sphere of radius *r* leads to the following.

$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2}$$

(*a*) For the region $0 < r < r_1$, the enclosed charge is 0.

$$E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \boxed{0}$$

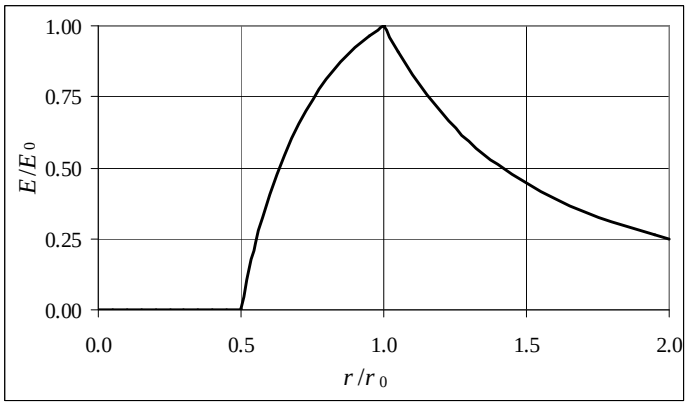
(*b*) For the region $r_1 < r < r_0$, the enclosed charge is the product of the volume charge density times the volume of charged material enclosed. The charge density is given by $\rho = \rho_0 \frac{r_1}{r}$. We must integrate to find the total charge. We follow the procedure given in Example 22-5. We divide the sphere up into concentric thin shells of thickness *dr*, as shown in Fig. 22-14. We then integrate to find the charge.

$$Q_{\text{encl}} = \int \rho_{\text{E}} dV = \int_{r_1}^{r} \rho_0 \frac{r_1}{r'} 4\pi\left(r'\right)^2 dr' = 4\pi r_1 \rho_0 \int_{r_1}^{r} r' dr' = 2\pi r_1 \rho_0 \left(r^2 - r_1^2\right)$$

$$E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \frac{2\pi r_1 \rho_0 \left(r^2 - r_1^2\right)}{4\pi\varepsilon_0 r^2} = \boxed{\frac{\rho_0 r_1 \left(r^2 - r_1^2\right)}{2\varepsilon_0 r^2}}$$

(*c*) For the region $r > r_0$, the enclosed charge is the total charge, found by integration in a similar fashion to part (*b*).

$$Q_{\text{encl}} = \int \rho_{\text{E}} dV = \int_{r_1}^{r_0} \rho_0 \frac{r_1}{r'} 4\pi\left(r'\right)^2 dr' = 4\pi r_1 \rho_0 \int_{r_1}^{r_0} r' dr' = 2\pi r_1 \rho_0 \left(r_0^2 - r_1^2\right)$$



$$E = \frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2} = \frac{2\pi r_1 \rho_0 \left(r_0^2 - r_1^2\right)}{4\pi\varepsilon_0 r^2} = \boxed{\frac{\rho_0 r_1 \left(r_0^2 - r_1^2\right)}{2\varepsilon_0 r^2}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*d*) See the attached graph. We have chosen $r_1 = \frac{1}{2} r_0$. Let

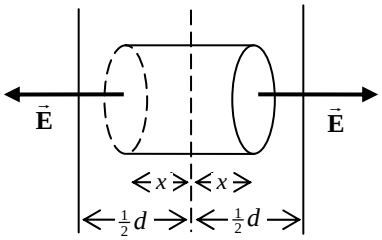
$$E_0 = E\left(r = r_0\right) = \frac{\rho_0 r_1 \left(r_0^2 - r_1^2\right)}{2\varepsilon_0 r_0^2}.$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH22.XLS," on tab "Problem 22.44d."

45. (*a*) The force felt by one plate will be the charge on that plate multiplied by the electric field caused by the other plate. The field due to one plate is found in Example 22-7. Let the positive plate be on the left, and the negative plate on the right. We find the force on the negative plate due to the positive plate.

$$F_{\substack{\text{on} \\ \text{plate} \\ \text{"b"}}} = q_{\substack{\text{on} \\ \text{plate} \\ \text{"b"}}} E_{\substack{\text{due to} \\ \text{plate} \\ \text{"a"}}} = \left(\sigma_b A_b\right) E_a = \left(\sigma_b A_b\right) \frac{\sigma_a}{2\varepsilon_0}$$

$$= \frac{\left(-15\times10^{-6}\,\text{C/m}^2\right)\left(1.0\,\text{m}^2\right)\left(-15\times10^{-6}\,\text{C/m}^2\right)}{2\left(8.85\times10^{-12}\,\text{C}^2/\text{Nm}^2\right)} = -12.71\,\text{N}$$



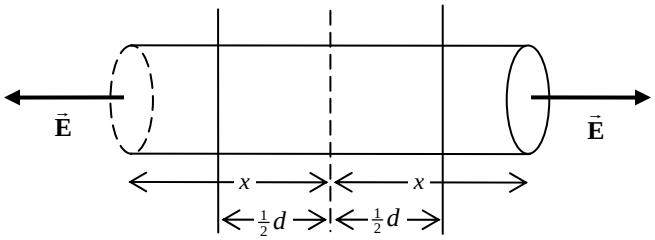
$$\approx \boxed{13\,\text{N, towards the other plate}}$$

(*b*) Since the field due to either plate is constant, the force on the other plate is constant, and then the work is just the force times the distance. Since the plates are oppositely charged, they will attract, and so a force equal to and opposite the force above will be required to separate them. The force will be in the same direction as the displacement of the plates.

$$W = \vec{\mathbf{F}} \bullet \Delta\vec{\mathbf{x}} = \left(12.71\,\text{N}\right)\left(\cos 0°\right)\left(5.0\times10^{-3}\,\text{m}\right) = \boxed{0.064\,\text{J}}$$

46. Because the slab is very large, and we are considering only distances from the slab much less than its height or breadth, the symmetry of the slab results in the field being perpendicular to the slab, with a constant magnitude for a constant distance from the center. We assume that $\rho_E > 0$ and so the electric field points away from the center of the slab.

(*a*) To determine the field inside the slab, choose a cylindrical gaussian surface, of length $2x < d$ and cross-sectional area *A*. Place it so that it is centered in the slab. There will be no flux through the curved wall of the cylinder. The electric field is parallel to the surface area vector on both ends, and is the same magnitude on both ends. Apply Gauss's law to find the electric field at a distance $x < \frac{1}{2} d$ from the center of the slab. See the first diagram.

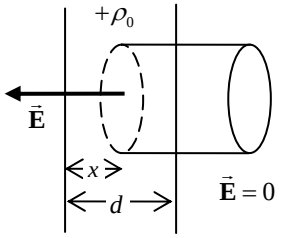


$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + \int_{\text{side}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + 0 = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad 2EA = \frac{\rho\left(2xA\right)}{\varepsilon_0} \quad \rightarrow$$

$$\boxed{E_{\text{inside}} = \frac{\rho x}{\varepsilon_0};\ |x| < \tfrac{1}{2} d}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Use a similar arrangement to determine the field outside the slab. Now let $2x > d$. See the second diagram.



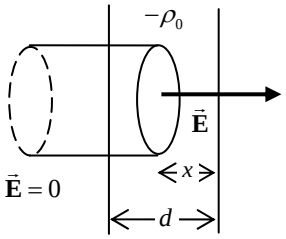
$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow$$

$$2EA = \frac{\rho(dA)}{\varepsilon_0} \quad \rightarrow \quad \boxed{E_{\text{outside}} = \frac{\rho d}{2\varepsilon_0};\ |x| > \tfrac{1}{2}d}$$

Notice that electric field is continuous at the boundary of the slab.

47. (*a*) In Problem 46, it is shown that the field outside a flat slab of nonconducting material with a uniform charge density is given by $E = \dfrac{\rho d}{2\varepsilon_0}$. If the charge density is positive, the field points away from the slab, and if the charge density is negative, the field points towards the slab. So for this problem's configuration, the field outside of both half-slabs is the vector sum of the fields from each half-slab. Since those fields are equal in magnitude and opposite in direction, the field outside the slab is $\boxed{0}$.

(*b*) To find the field in the positively charged half-slab, we use a cylindrical gaussian surface of cross sectional area *A*. Place it so that its left end is in the positively charged half-slab, a distance $x > 0$ from the center of the slab. Its right end is external to the slab. Due to the symmetry of the configuration, there will be no flux through the curved wall of the cylinder. The electric field is parallel to the surface area vector on the left end, and is 0 on the right end. We assume that the electric field is pointing to the left. Apply Gauss's law to find the electric field a distance $0 < x < d$ from the center of the slab. See the diagram.



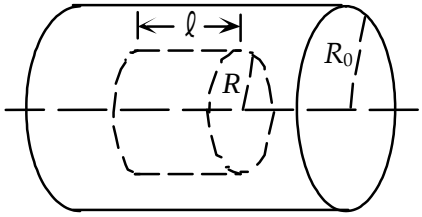
$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + \int_{\text{side}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\substack{\text{left}\\ \text{end}}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + 0 = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow$$

$$EA = \frac{\rho_0 (d - x) A}{\varepsilon_0} \quad \rightarrow \quad E_{x>0} = \frac{\rho_0 (d - x)}{\varepsilon_0}$$

Since the field is pointing to the left, we can express this as $\boxed{E_{x>0} = -\dfrac{\rho_0 (d - x)}{\varepsilon_0}\hat{\mathbf{i}}}$.

(*c*) To find the field in the negatively charged half-slab, we use a cylindrical gaussian surface of cross sectional area *A*. Place it so that its right end is in the negatively charged half-slab, a distance $x < 0$ from the center of the slab. Its left end is external to the slab. Due to the symmetry of the configuration, there will be no flux through the curved wall of the cylinder. The electric field is parallel to the surface area vector on the left end, and is 0 on the right end. We assume that the electric field is pointing to the right. Apply Gauss's law to find the electric field at a distance $-d < x < 0$ from the center of the slab. See the diagram.

$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + \int_{\text{side}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\substack{\text{right}\\ \text{end}}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + 0 = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$EA = \frac{-\rho_0 (d+x) A}{\varepsilon_0} \quad \rightarrow \quad E_{x<0} = \frac{-\rho_0 (d+x)}{\varepsilon_0}$$

Since the field is pointing to the left, we can express this as $\boxed{E_{x<0} = -\frac{\rho_0 (d+x)}{\varepsilon_0}\hat{\mathbf{i}}}$.

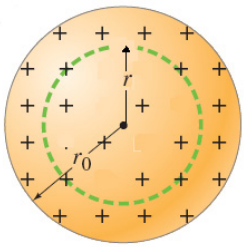
Notice that the field is continuous at all boundaries. At the left edge $(x = -d)$, $E_{x<0} = E_{\text{outside}}$. At the center $(x = 0)$, $E_{x<0} = E_{>0}$. And at the right edge $(x = d)$, $E_{x>0} = E_{\text{outside}}$.

48. We follow the development of Example 22-6. Because of the symmetry, we expect the field to be directed radially outward (no fringing effects near the ends of the cylinder) and to depend only on the perpendicular distance, *R*, from the symmetry axis of the cylinder. Because of the cylindrical symmetry, the field will be the same at all points on a gaussian surface that is a cylinder whose axis coincides with the axis of the cylinder.

The gaussian surface is of radius *r* and length ℓ. $\vec{\mathbf{E}}$ is perpendicular to this surface at all points. In order to apply Gauss's law, we need a closed surface, so we include the flat ends of the cylinder. Since $\vec{\mathbf{E}}$ is parallel to the flat ends, there is no flux through the ends. There is only flux through the curved wall of the gaussian cylinder.

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E(2\pi R\ell) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell}$$

To find the field inside the cylinder, we must find the charge enclosed in the gaussian cylinder. We divide the gaussian cylinder up into coaxial thin cylindrical shells of length ℓ and thickness *dR*. That shell has volume $dV = 2\pi R\ell dR$. The total charge in the gaussian cylinder is found by integration.



$$R < R_0: \quad Q_{\text{encl}} = \int_0^R \rho_E dV = \int_0^R \rho_0 \left(\frac{R}{R_0}\right)^2 2\pi R\ell\, dR = \frac{2\pi\rho_0\ell}{R_0^2}\int_0^R R^3\, dR = \frac{\pi\rho_0\ell R^4}{2R_0^2}$$

$$E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{\frac{\pi\rho_0\ell R^4}{2R_0^2}}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\rho_0 R^3}{4\varepsilon_0 R_0^2}, \text{ radially out}}$$

$$R < R_0: \quad Q_{\text{encl}} = \int_0^{R_0} \rho_E dV = \frac{2\pi\rho_0\ell}{R_0^2}\int_0^{R_0} R^3\, dR = \frac{\pi\rho_0\ell R_0^2}{2}$$

$$E = \frac{Q_{\text{encl}}}{2\pi\varepsilon_0 R\ell} = \frac{\frac{\pi\rho_0\ell R_0^2}{2}}{2\pi\varepsilon_0 R\ell} = \boxed{\frac{\rho_0 R_0^2}{4\varepsilon_0 R}, \text{ radially out}}$$

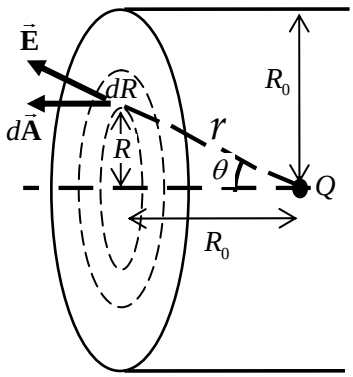
49. The symmetry of the charge distribution allows the electric field inside the sphere to be calculated using Gauss's law with a concentric gaussian sphere of radius $r \le r_0$. The enclosed charge will be found by integrating the charge density over the enclosed volume.

$$Q_{\text{encl}} = \int \rho_E dV = \int_0^r \rho_0 \left(\frac{r'}{r_0}\right) 4\pi r'^2 dr' = \frac{\rho_0 \pi r^4}{r_0}$$

The enclosed charge can be written in terms of the total charge by setting

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$r = r_0$ and solving for the charge density in terms of the total charge.



$$Q = \frac{\rho_0 \pi r_0^4}{r_0} = \rho_0 \pi r_0^3 \quad \rightarrow \quad \rho_0 = \frac{Q}{\pi r_0^3} \quad \rightarrow \quad Q_{\text{encl}}(r) = \frac{\rho_0 \pi r^4}{r_0} = Q\left(\frac{r}{r_0}\right)^4$$

The electric field is then found from Gauss's law

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E\left(4\pi r^2\right) = \frac{Q}{\varepsilon_0}\left(\frac{r}{r_0}\right)^4 \quad \rightarrow \quad E = \boxed{\frac{Q}{4\pi\varepsilon_0}\frac{r^2}{r_0^4}}$$

The electric field points radially outward since the charge distribution is positive.

50. By Gauss's law, the total flux through the cylinder is Q/ε_0. We find the flux through the ends of the cylinder, and then subtract that from the total flux to find the flux through the curved sides. The electric field is that of a point charge. On the ends of the cylinder, that field will vary in both magnitude and direction. Thus we must do a detailed integration to find the flux through the ends of the cylinder. Divide the ends into a series of concentric circular rings, of radius *R* and thickness *dR*. Each ring will have an area of $2\pi R dR$. The angle between $\vec{\mathbf{E}}$ and $d\vec{\mathbf{A}}$ is θ, where $\tan\theta = R/R_0$. See the diagram of the left half of the cylinder.

$$\Phi_{\substack{\text{left}\\\text{end}}} = \int \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \int_0^{R_0} \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2}\cos\theta\left(2\pi R\right)dR$$

The flux integral has three variables: *r*, *R*, and θ. We express *r* and θ in terms of *R* in order to integrate. The anti-derivative is found in Appendix B-4.

$$r = \sqrt{R^2 + R_0^2} \;;\; \cos\theta = \frac{R_0}{r} = \frac{R_0}{\sqrt{R^2 + R_0^2}}$$

$$\Phi_{\substack{\text{left}\\\text{end}}} = \int_0^{R_0} \frac{1}{4\pi\varepsilon_0}\frac{Q}{\left(R^2 + R_0^2\right)}\frac{R_0}{\sqrt{R^2 + R_0^2}}\left(2\pi R\right)dR = \frac{2\pi Q R_0}{4\pi\varepsilon_0}\int_0^{R_0}\frac{R\,dR}{\left(R^2 + R_0^2\right)^{3/2}} = \frac{QR_0}{2\varepsilon_0}\left[-\frac{1}{\sqrt{R^2 + R_0^2}}\right]_0^{R_0}$$

$$= \frac{Q}{2\varepsilon_0}\left[1 - \frac{1}{\sqrt{2}}\right] \;;\; \Phi_{\substack{\text{both}\\\text{ends}}} = 2\Phi_{\substack{\text{left}\\\text{end}}} = \frac{Q}{\varepsilon_0}\left[1 - \frac{1}{\sqrt{2}}\right]$$

$$\Phi_{\text{total}} = \frac{Q}{\varepsilon_0} = \Phi_{\text{sides}} + \Phi_{\substack{\text{both}\\\text{ends}}} \quad \rightarrow \quad \Phi_{\text{sides}} = \frac{Q}{\varepsilon_0} - \Phi_{\substack{\text{both}\\\text{ends}}} = \frac{Q}{\varepsilon_0} - \frac{Q}{\varepsilon_0}\left[1 - \frac{1}{\sqrt{2}}\right] = \boxed{\frac{Q}{\sqrt{2}\varepsilon_0}}$$

51. The gravitational field a distance *r* from a point mass *M* is given by Eq. 6-8, $\vec{\mathbf{g}} = -\frac{GM}{r^2}\hat{\mathbf{r}}$, where $\hat{\mathbf{r}}$ is a unit vector pointing radially outward from mass *M*. Compare this to the electric field of a point charge, $\vec{\mathbf{E}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2}\hat{\mathbf{r}}$. To change the electric field to the gravitational field, we would make these changes: $\vec{\mathbf{E}} \rightarrow \vec{\mathbf{g}}$; $Q/\varepsilon_0 \rightarrow -4\pi GM$. Make these substitutions in Gauss's law.

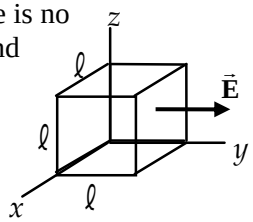
$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad \boxed{\oint \vec{\mathbf{g}} \cdot d\vec{\mathbf{A}} = -4\pi GM_{\text{encl}}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

52. (*a*) We use Gauss's law for a spherically symmetric charge distribution, and assume that all the charge is on the surface of the Earth. Note that the field is pointing radially inward, and so the dot product introduces a negative sign.

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = -E\left(4\pi r^2\right) = Q_{\text{encl}} / \varepsilon_0 \quad \rightarrow$$

$$Q_{\text{encl}} = -4\pi\varepsilon_0 E R_{\text{Earth}}^2 = \frac{-\left(150\ \text{N/C}\right)\left(6.38\times10^6\ \text{m}\right)^2}{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)} = -6.793\times10^5\ \text{C} \approx \boxed{-6.8\times10^5\ \text{C}}$$



(*b*) Find the surface density of electrons. Let *n* be the total number of electrons.

$$\sigma = \frac{Q}{A} = -\frac{ne}{A} \quad \rightarrow$$

$$\frac{n}{A} = -\frac{Q}{eA} = -\frac{-4\pi\varepsilon_0 E R_{\text{Earth}}^2}{e\left(4\pi R_{\text{Earth}}^2\right)} = \frac{\varepsilon_0 E}{e} = \frac{\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(150\ \text{N/C}\right)}{\left(1.60\times10^{-19}\ \text{C}\right)}$$

$$= \boxed{8.3\times10^9\ \text{electrons/m}^2}$$

53. The electric field is strictly in the *y* direction. So, referencing the diagram, there is no flux through the top, bottom, front, or back faces of the cube. Only the "left" and "right" faces will have flux through them. And since the flux is only dependent on the *y* coordinate, the flux through each of those two faces is particularly simple. Calculate the flux and use Gauss's law to find the enclosed charge.

$$\Phi = \oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \int_{\substack{\text{left}\\\text{face}}} \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} + \int_{\substack{\text{right}\\\text{face}}} \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}}$$

$$= \int_{\substack{\text{left}\\\text{face}}} b\hat{\mathbf{j}} \cdot \left(-\hat{\mathbf{j}} dA\right) + \int_{\substack{\text{right}\\\text{face}}} \left(a\ell + b\right)\hat{\mathbf{j}} \cdot \left(\hat{\mathbf{j}} dA\right) = -b\ell^2 + a\ell^3 + b\ell^2$$

$$= a\ell^3 = Q_{\text{encl}} / \varepsilon_0 \quad \rightarrow \quad Q_{\text{encl}} = \boxed{\varepsilon_0 a\ell^3}$$

54. (*a*) Find the value of *b* by integrating the charge density over the entire sphere. Follow the development given in Example 22-5.

$$Q = \int \rho_{\text{E}} dV = \int_0^{r_0} br\left(4\pi r^2 dr\right) = 4\pi b\left(\tfrac{1}{4} r_0^4\right) \quad \rightarrow \quad b = \boxed{\frac{Q}{\pi r_0^4}}$$

(*b*) To find the electric field inside the sphere, we apply Gauss's law to an imaginary sphere of radius *r*, calculating the charge enclosed by that sphere. The spherical symmetry allows us to evaluate the flux integral simply.

$$\Phi = \oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\varepsilon_0} \ ; \ Q = \int \rho_{\text{E}} dV = \int_0^r \frac{Q}{\pi r_0^4} r\left(4\pi r^2 dr\right) = \frac{Qr^4}{r_0^4} \quad \rightarrow$$

$$E = \boxed{\frac{1}{4\pi\varepsilon_0}\frac{Qr^2}{r_0^4},\ r < r_0}$$

(*c*) As discussed in Example 22-4, the field outside a spherically symmetric distribution of charge is the same as that for a point charge of the same magnitude located at the center of the sphere.

$$\boxed{E = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2},\ r > r_0}$$

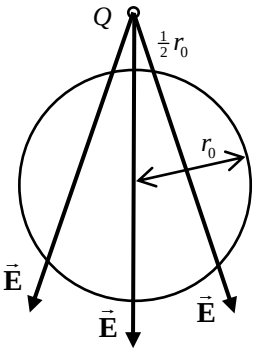
55. The flux through a gaussian surface depends only on the charge enclosed by the surface. For both of these spheres the two point charges are enclosed within the sphere. Therefore the flux is the same for both spheres.



$$\Phi = \frac{Q_{\text{encl}}}{\varepsilon_0} = \frac{\left(9.20\times10^{-9}\,\text{C}\right)+\left(-5.00\times10^{-9}\,\text{C}\right)}{8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2} = \boxed{475\,\text{N}\cdot\text{m}^2/\text{C}}$$

56. (*a*) The flux through any closed surface containing the total charge must be the same, so the flux through the larger sphere is the same as the flux through the smaller sphere, $\boxed{+235\,\text{N}\cdot\text{m}^2/\text{C}}$.

(*b*) Use Gauss's law to determine the enclosed charge.

$$\Phi = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad\rightarrow\quad Q_{\text{encl}} = \varepsilon_0\Phi = \left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(+235\,\text{N}\cdot\text{m}^2/\text{C}\right) = \boxed{2.08\times10^{-9}\,\text{C}}$$

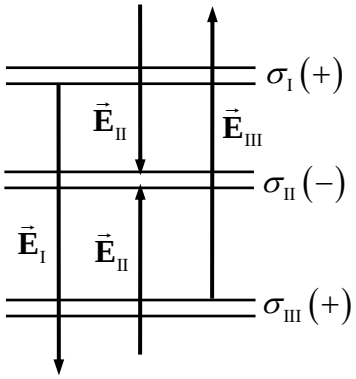
57. (*a*) There is no charge enclosed within the sphere, and so no flux lines can originate or terminate inside the sphere. All field lines enter and leave the sphere. Thus the net flux is $\boxed{0}$.

(*b*) The maximum electric field will be at the point on the sphere closest to *Q*, which is the top of the sphere. The minimum electric field will be at the point on the sphere farthest from Q, which is the bottom of the sphere.

$$E_{\text{max}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r_{\text{closest}}^2} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{\left(\frac{1}{2}r_0\right)^2} = \boxed{\frac{1}{\pi\varepsilon_0}\frac{Q}{r_0^2}}$$

$$E_{\text{min}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r_{\text{farthest}}^2} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{\left(\frac{5}{2}r_0\right)^2} = \boxed{\frac{1}{25\pi\varepsilon_0}\frac{Q}{r_0^2}}$$

Thus the range of values is $\boxed{\dfrac{1}{\pi\varepsilon_0}\dfrac{Q}{r_0^2} \le E_{\substack{\text{sphere}\\\text{surface}}} \le \dfrac{1}{25\pi\varepsilon_0}\dfrac{Q}{r_0^2}}$.



(*c*) $\vec{\mathbf{E}}$ is $\boxed{\text{not perpendicular}}$ at all points. It is only perpendicular at the two points already discussed: the point on the sphere closest to the point charge, and the point on the sphere farthest from the point charge.

(*d*) The electric field is not perpendicular or constant over the surface of the sphere. Therefore Gauss's law is $\boxed{\text{not useful}}$ for obtaining E at the surface of the sphere because a gaussian surface cannot be chosen that simplifies the flux integral.

58. The force on a sheet is the charge on the sheet times the average electric field due to the other sheets: But the fields due to the "other" sheets is uniform, so the field is the same over the entire sheet. The force per unit area is then the charge per unit area, times the field due to the other sheets.

$$F_{\substack{\text{on}\\\text{sheet}}} = q_{\substack{\text{on}\\\text{sheet}}}\,\vec{E}_{\substack{\text{other}\\\text{sheets}}} = q_{\substack{\text{on}\\\text{sheet}}}\,E_{\substack{\text{other}\\\text{sheets}}} \quad\rightarrow$$

$$\left(\frac{F}{A}\right)_{\substack{\text{on}\\\text{sheet}}} = \left(\frac{q}{A}\right)_{\substack{\text{on}\\\text{sheet}}} E_{\substack{\text{other}\\\text{sheets}}} = \sigma_{\substack{\text{on}\\\text{sheet}}}\,E_{\substack{\text{other}\\\text{sheets}}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The uniform fields from each of the three sheets are indicated on the diagram. Take the positive direction as upwards. We take the direction from the diagram, and so use the absolute value of each charge density. The electric field magnitude due to each sheet is given by $E = \sigma/2\varepsilon_0$.

$$\left(\frac{F}{A}\right)_{\text{I}} = \sigma_{\text{I}}\left(E_{\text{III}} - E_{\text{II}}\right) = \frac{\sigma_{\text{I}}}{2\varepsilon_0}\left(|\sigma_{\text{III}}| - |\sigma_{\text{II}}|\right) = \frac{6.5\times10^{-9}\ \text{C/m}^2}{2\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}\left[\left(5.0-2.0\right)\times10^{-9}\ \text{C/m}^2\right]$$

$$= \boxed{1.1\times10^{-6}\ \text{N/m}^2\ \ (\text{up})}$$

$$\left(\frac{F}{A}\right)_{\text{II}} = \sigma_{\text{II}}\left(E_{\text{III}} - E_{\text{I}}\right) = \frac{\sigma_{\text{II}}}{2\varepsilon_0}\left(|\sigma_{\text{III}}| - |\sigma_{\text{I}}|\right) = \frac{-2.0\times10^{-9}\ \text{C/m}^2}{2\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}\left[\left(5.0-6.5\right)\times10^{-9}\ \text{C/m}^2\right]$$

$$= \boxed{1.7\times10^{-7}\ \text{N/m}^2\ \ (\text{up})}$$

$$\left(\frac{F}{A}\right)_{\text{III}} = \sigma_{\text{III}}\left(E_{\text{III}} - E_{\text{I}}\right) = \frac{\sigma_{\text{III}}}{2\varepsilon_0}\left(|\sigma_{\text{II}}| - |\sigma_{\text{I}}|\right) = \frac{5.0\times10^{-9}\ \text{C/m}^2}{2\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)}\left[\left(2.0-6.5\right)\times10^{-9}\ \text{C/m}^2\right]$$

$$= \boxed{-1.3\times10^{-6}\ \text{N/m}^2\ \ (\text{down})}$$

59. (*a*) The net charge inside a sphere of radius a_0 will be made of two parts – the positive point charge at the center of the sphere, and some fraction of the total negative charge, since the negative charge is distributed over all space, as described by the charge density. To evaluate the portion of the negative charge inside the sphere, we must determine the coefficient *A*. We do that by integrating the charge density over all space, in the manner of Example 22-5. Use an integral from Appendix B-5.

$$-e = \int \rho_E dV = \int_0^\infty \left(-Ae^{-2r/a_0}\right)\left(4\pi r^2 dr\right) = -4\pi A\int_0^\infty e^{-2r/a_0} r^2 dr = -4\pi A\frac{2!}{\left(2/a_0\right)^3} = -\pi A a_0^3 \quad \rightarrow$$

$$A = \frac{e}{\pi a_0^3}$$

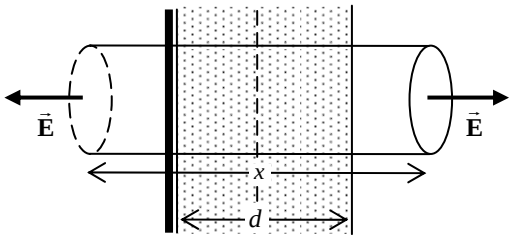
Now we find the negative charge inside the sphere of radius a_0, using an integral from Appendix B-4. We are indicating the elementary charge by (e), so as to not confuse it with the base of the natural logarithms.

$$Q_{\text{neg}} = \int_0^{a_0}\left(-Ae^{-2r/a_0}\right)\left(4\pi r^2 dr\right) = -\frac{4\pi(e)}{\pi a_0^3}\int_0^{a_0} e^{-2r/a_0} r^2 dr$$

$$= -\frac{4\pi(e)}{\pi a_0^3}\left\{\left[-\frac{e^{-2r/a_0}}{\left(2/a_0\right)^3}\right]\left[\left(2/a_0\right)^2 r^2 + 2\left(2/a_0\right)r + 2\right]\right\}_0^{a_0} = (e)\left[5e^{-2} - 1\right]$$

$$Q_{\text{net}} = Q_{\text{neg}} + Q_{\text{pos}} = (e)\left[5e^{-2} - 1\right] + (e) = (e)5e^{-2} = \left(1.6\times10^{-19}\text{C}\right)5e^{-2} = 1.083\times10^{-19}\text{C}$$

$$\approx \boxed{1.1\times10^{-19}\text{C}}$$



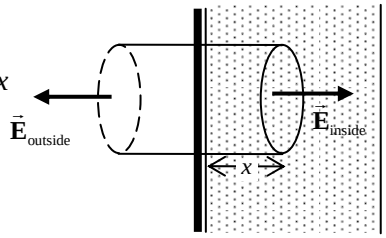
(*b*) The field at a distance $r = a_0$ is that of a point charge of magnitude Q_{net} at the origin, because of the spherical symmetry and Gauss's law.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{net}}}{a_0^2} = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left(1.083\times10^{-19}\text{C}\right)}{\left(0.53\times10^{-10}\text{m}\right)^2} = \boxed{3.5\times10^{11}\ \text{N/C}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

60. The field due to the plane is $E_{\text{plane}} = \dfrac{\sigma}{2\varepsilon_0}$, as discussed in Example 22-7. Because the slab is very large, and we assume that we are considering only distances from the slab much less than its height or breadth, the symmetry of the slab results in its field being perpendicular to the slab, with a constant magnitude for a constant distance from its center. We also assume that $\rho_{\text{E}} > 0$ and so the electric field of the slab points away from the center of the slab.

(*a*) To determine the field to the left of the plane, we choose a cylindrical gaussian surface, of length $x > d$ and cross-sectional area *A*. Place it so that the plane is centered inside the cylinder. See the diagram. There will be no flux through the curved wall of the cylinder. From the symmetry, the electric field is parallel to the surface area vector on both ends. We already know that the field due to the plane is the same on both ends, and by the symmetry of the problem, the field due to the slab must also be the same on both ends. Thus the total field is the same magnitude on both ends.



$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + \int_{\text{side}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\text{ends}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + 0 = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad 2E_{\text{outside}} A = \frac{\sigma A + \rho_{\text{E}} dA}{\varepsilon_0} \quad \rightarrow$$

$$E_{\substack{\text{outside} \\ \text{left} \\ \text{of plane}}} = \boxed{\frac{\sigma + \rho_{\text{E}} d}{2\varepsilon_0}}$$

(*b*) As argued above, the field is symmetric on the outside of the charged matter.

$$E_{\substack{\text{right} \\ \text{of plane}}} = \boxed{\frac{\sigma + \rho_{\text{E}} d}{2\varepsilon_0}}$$

(*c*) To determine the field inside the slab, we choose a cylindrical gaussian surface of cross-sectional area *A* with one face to the left of the plane, and the other face inside the slab, a distance *x* from the plane. Due to symmetry, the field again is parallel to the surface area vector on both ends, has a constant value on each end, and no flux pierces the curved walls. Apply Gauss's law.

$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = \int_{\substack{\text{left} \\ \text{end}}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + \int_{\substack{\text{right} \\ \text{end}}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} + \int_{\text{side}} \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = E_{\text{outside}} A + E_{\text{inside}} A + 0 = \frac{Q_{\text{encl}}}{\varepsilon_0}$$

$$Q_{\text{encl}} = \sigma A + \rho_{\text{E}} xA \quad \rightarrow \quad \left(\frac{\sigma + \rho_{\text{E}} d}{2\varepsilon_0} \right) A + E_{\text{inside}} A = \frac{\sigma A + \rho_{\text{E}} xA}{\varepsilon_0} \quad \rightarrow$$

$$E_{\text{inside}} = \boxed{\frac{\sigma + \rho_{\text{E}} (2x - d)}{2\varepsilon_0}}, \; 0 < x < d$$

Notice that the field is continuous from "inside" to "outside" at the right edge of the slab, but not at the left edge of the slab. That discontinuity is due to the surface charge density.

61. Consider this sphere as a combination of two spheres. Sphere 1 is a solid sphere of radius r_0 and charge density ρ_E centered at A and sphere 2 is a second sphere of radius $r_0/2$ and density $-\rho_E$ centered at C.

(*a*) The electric field at A will have zero contribution from sphere 1 due to its symmetry about point A. The electric field is then calculated by creating a gaussian surface centered at point C with radius $r_0/2$.

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \frac{q_{\text{enc}}}{\varepsilon_0} \rightarrow E \cdot 4\pi\left(\tfrac{1}{2}r_0\right)^2 = \frac{\left(-\rho_E\right)\frac{4}{3}\pi\left(\frac{1}{2}r_0\right)^3}{\varepsilon_0} \rightarrow \boxed{E = -\frac{\rho_E r_0}{6\varepsilon_0}}$$

Since the electric field points into the gaussian surface (negative) the electric field at point A points to the right.

(*b*) At point B the electric field will be the sum of the electric fields from each sphere. The electric field from sphere 1 is calculated using a gaussian surface of radius r_0 centered at A.

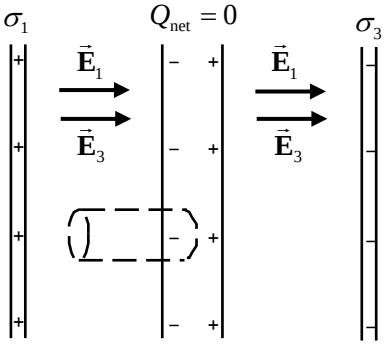
$$\oint \vec{\mathbf{E}}_1 \cdot d\vec{\mathbf{A}} = \frac{q_{\text{enc}}}{\varepsilon_0} \rightarrow E_1 \cdot 4\pi r_0^2 = \frac{\frac{4}{3}\pi r_0^3\left(\rho_E\right)}{\varepsilon_0} \rightarrow E_1 = \frac{\rho_E r_0}{3\varepsilon_0}$$

At point B the field from sphere 1 points toward the left. The electric field from sphere 2 is calculated using a gaussian surface centered at C of radius $3r_0/2$.

$$\oint \vec{\mathbf{E}}_2 \cdot d\vec{\mathbf{A}} = \frac{q_{\text{enc}}}{\varepsilon_0} \rightarrow E_2 \cdot 4\pi\left(\tfrac{3}{2}r_0\right)^2 = \frac{\left(-\rho_E\right)\frac{4}{3}\pi\left(\frac{1}{2}r_0\right)^3}{\varepsilon_0} \rightarrow E_2 = -\frac{\rho_E r_0}{54\varepsilon_0}$$

At point B, the electric field from sphere 2 points toward the right. The net electric field is the sum of these two fields. The net field points to the left.

$$E = E_1 + E_2 = \frac{\rho_E r_0}{3\varepsilon_0} + \frac{-\rho_E r_0}{54\varepsilon_0} = \boxed{\frac{17\rho_E r_0}{54\varepsilon_0}}.$$



62. We assume the charge is uniformly distributed, and so the field of the pea is that of a point charge.

$$E\left(r = R\right) = \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2} \rightarrow$$

$$Q = E4\pi\varepsilon_0 R^2 = \left(3\times10^6\ \text{N/C}\right)4\pi\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(0.00375\,\text{m}\right)^2 = \boxed{5\times10^{-9}\,\text{C}}$$

63. (*a*) In an electrostatic situation, there is no electric field inside a conductor. Thus $E = \boxed{0}$ inside the conductor.

(*b*) The positive sheet produces an electric field, external to itself, directed away from the plate with a magnitude as given in Example 22-7, of $E_1 = \dfrac{|\sigma_1|}{2\varepsilon_0}$. The negative sheet produces an electric field, external to itself, directed towards the plate with a magnitude of $E_2 = \dfrac{|\sigma_2|}{2\varepsilon_0}$. Between the left and middle sheets, those two fields are parallel and so add to each other.

$$E_{\substack{\text{left}\\\text{middle}}} = E_1 + E_2 = \frac{|\sigma_1| + |\sigma_2|}{2\varepsilon_0} = \frac{2\left(5.00\times10^{-6}\ \text{C/m}^2\right)}{2\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)} = \boxed{5.65\times10^5\ \text{N/C}}, \text{ to the right}$$

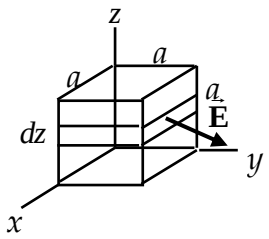
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) The same field is between the middle and right sheets. See the diagram.

$$E_{\substack{\text{middle}\\\text{right}}} = \boxed{5.65\times10^{5}\ \text{N/C}}, \text{ to the right}$$

(*d*) To find the charge density on the surface of the left side of the middle sheet, choose a gaussian cylinder with ends of area *A*. Let one end be inside the conducting sheet, where there is no electric field, and the other end be in the area between the left and middle sheets. Apply Gauss's law in the manner of Example 22-16. Note that there is no flux through the curved sides of the cylinder, and there is no flux through the right end since it is in conducting material. Also note that the field through the left end is in the opposite direction as the area vector of the left end.

$$\oint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = \int_{\substack{\text{left}\\\text{end}}} \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} + \int_{\substack{\text{right}\\\text{end}}} \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} + \int_{\text{side}} \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = -E_{\substack{\text{left}\\\text{middle}}} A + 0 + 0 = \frac{Q_{\text{encl}}}{\varepsilon_0} = \frac{\sigma_{\text{left}} A}{\varepsilon_0} \quad \rightarrow$$



$$\sigma_{\text{left}} = -\varepsilon_0 E_{\substack{\text{left}\\\text{middle}}} = -\varepsilon_0\left(\frac{|\sigma_1| + |\sigma_2|}{2\varepsilon_0}\right) = \boxed{-5.00\times10^{-6}\ \text{C/m}^2}$$

(*e*) Because the middle conducting sheet has no net charge, the charge density on the right side must be the opposite of the charge density on the left side.

$$\sigma_{\text{right}} = -\sigma_{\text{left}} = \boxed{5.00\times10^{-6}\ \text{C/m}^2}$$

Alternatively, we could have applied Gauss's law on the right side in the same manner that we did on the left side. The same answer would result.

64. Because the electric field has only *x* and *y* components, there will be no flux through the top or bottom surfaces. For the other faces, we choose a horizontal strip of height *dz* and width *a* for a differential element and integrate to find the flux. The total flux is used to determine the enclosed charge.

$$\Phi_{\substack{\text{front}\\(x=a)}} = \int \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = \int_0^a \left[E_0\left(1+\frac{z}{a}\right)\hat{\mathbf{i}} + E_0\left(\frac{z}{a}\right)\hat{\mathbf{j}}\right]\bullet\left(a\,dz\,\hat{\mathbf{i}}\right)$$

$$= E_0 a\int_0^a \left(1+\frac{z}{a}\right)dz = E_0 a\left(z+\frac{z^2}{2a}\right)_0^a = \tfrac{3}{2}E_0 a^2$$

$$\Phi_{\substack{\text{back}\\(x=0)}} = \int_0^a \left[E_0\left(1+\frac{z}{a}\right)\hat{\mathbf{i}} + E_0\left(\frac{z}{a}\right)\hat{\mathbf{j}}\right]\bullet\left(-a\,dz\,\hat{\mathbf{i}}\right) = -\tfrac{3}{2}E_0 a^2$$

$$\Phi_{\substack{\text{right}\\(y=a)}} = \int_0^a \left[E_0\left(1+\frac{z}{a}\right)\hat{\mathbf{i}} + E_0\left(\frac{z}{a}\right)\hat{\mathbf{j}}\right]\bullet\left(a\,dz\,\hat{\mathbf{j}}\right) = E_0 a\int_0^a \left(\frac{z}{a}\right)dz = E_0 a\left(\frac{z^2}{2a}\right)_0^a = \tfrac{1}{2}E_0 a^2$$

$$\Phi_{\substack{\text{left}\\(y=a)}} = \int_0^a \left[E_0\left(1+\frac{z}{a}\right)\hat{\mathbf{i}} + E_0\left(\frac{z}{a}\right)\hat{\mathbf{j}}\right]\bullet\left(-a\,dz\,\hat{\mathbf{j}}\right) = -\tfrac{1}{2}E_0 a^2$$

$$\Phi_{\text{total}} = \Phi_{\text{front}} + \Phi_{\text{back}} + \Phi_{\text{right}} + \Phi_{\text{left}} + \Phi_{\text{top}} + \Phi_{\text{bottom}} = \tfrac{3}{2}E_0 a^2 - \tfrac{3}{2}E_0 a^2 + \tfrac{1}{2}E_0 a^2 - \tfrac{1}{2}E_0 a^2 = 0 + 0$$

$$= 0 = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad \boxed{Q_{\text{encl}} = 0}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

65. (*a*) Because the shell is a conductor, there is no electric field in the conducting material, and all charge must reside on its surfaces. All of the field lines that originate from the point charge at the center must terminate on the inner surface of the shell. Therefore the inner surface must have an equal but opposite charge to the point charge at the center. Since the conductor has the same magnitude of charge as the point charge at the center, all of the charge on the conductor is on the inner surface of the shell, in a spherically symmetric distribution.

(*b*) By Gauss's law and the spherical symmetry of the problem, the electric field can be calculated by $E = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q_{\text{encl}}}{r^2}$.

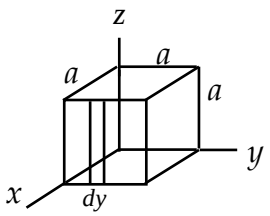
$$r < 0.10\,\text{m}: \; E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.0\times10^{-6}\,\text{C}\right)}{r^2} = \boxed{\frac{2.7\times10^4\ \text{N}\cdot\text{m}^2/\text{C}}{r^2}}$$

$$r > 0.15\,\text{m}: \; E = \boxed{0}$$

And since there is no electric field in the shell, we could express the second answer as $r > 0.10\,\text{m}: \; E = \boxed{0}$.

66. (*a*) At a strip such as is marked in the textbook diagram, $d\vec{\mathbf{A}}$ is perpendicular to the surface, and $\vec{\mathbf{E}}$ is inclined at an angle θ relative to $d\vec{\mathbf{A}}$.

$$\Phi_{\text{hemisphere}} = \int \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = \int_0^{\pi/2} E\cos\theta\left(2\pi R^2\sin\theta d\theta\right)$$



$$= 2\pi R^2 E\int_0^{\pi/2}\cos\theta\sin\theta d\theta = 2\pi R^2 E\left(\tfrac{1}{2}\sin^2\theta\right)_0^{\pi/2} = \pi R^2 E$$

(*b*) Choose a closed gaussian surface consisting of the hemisphere and the circle of radius *R* at the base of the hemisphere. There is no charge inside that closed gaussian surface, and so the total flux through the two surfaces (hemisphere and base) must be zero. The field lines are all perpendicular to the circle, and all of the same magnitude, and so that flux is very easy to calculate.

$$\Phi_{\text{circle}} = \int \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = \int E\left(\cos180°\right)d\vec{\mathbf{A}} = -EA = -E\pi R^2$$

$$\Phi_{\text{total}} = 0 = \Phi_{\text{circle}} + \Phi_{\text{hemisphere}} = -E\pi R^2 + \Phi_{\text{hemisphere}} \;\rightarrow\; \Phi_{\text{hemisphere}} = \boxed{\pi R^2 E}$$

67. The flux is the sum of six integrals, each of the form $\iint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}}$. Because the electric field has only *x* and *y* components, there will be no flux through the top or bottom surfaces. For the other faces, we choose a vertical strip of height *a* and width *dy* (for the front and back faces) or *dx* (for the left and right faces). See the diagram for an illustration of a strip on the front face. The total flux is then calculated, and used to determine the enclosed charge.

$$\Phi_{\substack{\text{front}\\(x=a)}} = \int_0^a \left(E_{x0}e^{-\left(\frac{x+y}{a}\right)^2}\hat{\mathbf{i}} + E_{y0}e^{-\left(\frac{x+y}{a}\right)^2}\hat{\mathbf{j}}\right)\bullet a dy\,\hat{\mathbf{i}} = aE_{x0}\int_0^a e^{-\left(\frac{a+y}{a}\right)^2}dy$$

This integral does not have an analytic anti-derivative, and so must be integrated numerically. We approximate the integral by a sum: $\displaystyle\int_0^a e^{-\left(\frac{a+y}{a}\right)^2}dy \approx \sum_{i=1}^{n} e^{-\left(\frac{a+y_i}{a}\right)^2}\Delta y$. The region of integration is divided

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

into n elements, and so $\Delta y = \dfrac{a-0}{n}$ and $y_i = i\Delta y$. We initially evaluate the sum for $n = 10$. Then we evaluate it for $n = 20$. If the two sums differ by no more than 2%, we take that as the value of the integral. If they differ by more than 2%, we choose a larger n, compute the sum, and compare that to the result for $n = 20$. We continue until a difference of 2% or less is reached. This integral, for $n = 100$ and $a = 1.0$ m, is 0.1335 m. So we have this intermediate result.

$$\Phi_{\substack{\text{front}\\(x=a)}} = aE_{x0}\sum_{i=1}^{n} e^{-\left(\frac{a+y_i}{a}\right)^2}\Delta y = (1.0\,\text{m})(50\,\text{N/C})(0.1335\,\text{m}) = 6.675\,\text{N}\cdot\text{m}^2/\text{C}$$

Now do the integral over the back face.

$$\Phi_{\substack{\text{back}\\(x=0)}} = \int_0^a \left(E_{x0}e^{-\left(\frac{x+y}{a}\right)^2}\hat{\mathbf{i}} + E_{y0}e^{-\left(\frac{x+y}{a}\right)^2}\hat{\mathbf{j}} \right)\cdot\left(-a\,dy\,\hat{\mathbf{i}}\right) = -aE_{x0}\int_0^a e^{-\left(\frac{y}{a}\right)^2} dy$$

We again get an integral that cannot be evaluated analytically. A similar process to that used for the front face is applied again, and so we make this approximation: $-aE_{x0}\int_0^a e^{-\left(\frac{y}{a}\right)^2} dy \approx -aE_{x0}\sum_{i=1}^{n} e^{-\left(\frac{y_i}{a}\right)^2}\Delta y$.

The numeric integration gives a value of 0.7405 m.

$$\Phi_{\substack{\text{back}\\(x=0)}} = -aE_{x0}\sum_{i=1}^{n} e^{-\left(\frac{y_i}{a}\right)^2}\Delta y = -(1.0\,\text{m})(50\,\text{N/C})(0.7405\,\text{m}) = -37.025\,\text{N}\cdot\text{m}^2/\text{C}.$$

Now consider the right side.

$$\Phi_{\substack{\text{right}\\(y=a)}} = \int_0^a \left(E_{x0}e^{-\left(\frac{x+y}{a}\right)^2}\hat{\mathbf{i}} + E_{y0}e^{-\left(\frac{x+y}{a}\right)^2}\hat{\mathbf{j}} \right)\cdot a\,dx\,\hat{\mathbf{j}} = aE_{y0}\int_0^a e^{-\left(\frac{x+a}{a}\right)^2} dx$$

Notice that the same integral needs to be evaluated as for the front side. All that has changed is the variable name. Thus we have the following.

$$\Phi_{\substack{\text{right}\\(y=a)}} = aE_{y0}\int_0^a e^{-\left(\frac{x+a}{a}\right)^2} dx \approx (1.0\,\text{m})(25\,\text{N/C})(0.1335\,\text{m}) = 3.3375\,\text{N}\cdot\text{m}^2/\text{C}$$

Finally, do the left side, following the same process. The same integral arises as for the back face.

$$\Phi_{\substack{\text{left}\\(y=0)}} = \int_0^a \left(E_{x0}e^{-\left(\frac{x+y}{a}\right)^2}\hat{\mathbf{i}} + E_{y0}e^{-\left(\frac{x+y}{a}\right)^2}\hat{\mathbf{j}} \right)\cdot\left(-a\,dx\,\hat{\mathbf{j}}\right) = -aE_{y0}\int_0^a e^{-\left(\frac{x}{a}\right)^2} dx$$

$$\approx -(1.0\,\text{m})(25\,\text{N/C})(0.7405\,\text{m}) = -18.5125\,\text{N}\cdot\text{m}^2/\text{C}$$

Sum to find the total flux, and multiply by ε_0 to find the enclosed charge.

$$\Phi_{\text{total}} = \Phi_{\text{front}} + \Phi_{\text{back}} + \Phi_{\text{right}} + \Phi_{\text{left}} + \Phi_{\text{top}} + \Phi_{\text{bottom}}$$

$$= (6.675 - 37.025 + 3.3375 - 18.5125)\,\text{N}\cdot\text{m}^2/\text{C} = -45.525\,\text{N}\cdot\text{m}^2/\text{C} \approx \boxed{-46\,\text{N}\cdot\text{m}^2/\text{C}}$$

$$Q_{\text{encl}} = \varepsilon_0\Phi_{\text{total}} = \left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(-45.525\,\text{N}\cdot\text{m}^2/\text{C}\right) = \boxed{-4.0\times10^{-10}\,\text{C}}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH22.XLS," on tab "Problem 22.67."

CHAPTER 23: Electric Potential

Responses to Questions

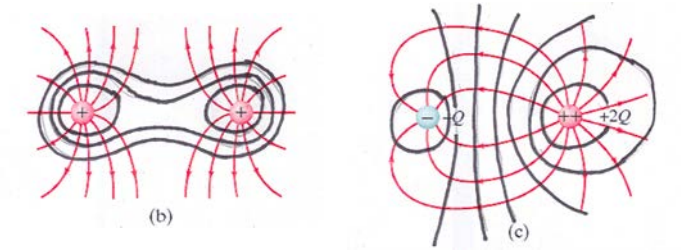
1. Not necessarily. If two points are at the same potential, then no *net* work is done in moving a charge from one point to the other, but work (both positive and negative) could be done at different parts of the path. No. It is possible that positive work was done over one part of the path, and negative work done over another part of the path, so that these two contributions to the net work sum to zero. In this case, a non-zero force would have to be exerted over both parts of the path.

2. The negative charge will move toward a region of higher potential and the positive charge will move toward a region of lower potential. In both cases, the potential energy of the charge will decrease.

3. (*a*) The electric potential is the electric potential energy per unit charge. The electric potential is a scalar. The electric field is the electric force per unit charge, and is a vector.
   (*b*) Electric potential is the electric potential energy per unit charge.

4. Assuming the electron starts from rest in both cases, the final speed will be twice as great. If the electron is accelerated through a potential difference that is four times as great, then its increase in kinetic energy will also be greater by a factor of four. Kinetic energy is proportional to the square of the speed, so the final speed will be greater by a factor of two.

5. Yes. If the charge on the particle is negative and it moves from a region of low electric potential to a region of high electric potential, its electric potential energy will decrease.



6. No. Electric potential is the *potential energy* per unit charge at a point in space and electric field is the *electric force* per unit charge at a point in space. If one of these quantities is zero, the other is not necessarily zero. For example, the point exactly between two charges with equal magnitudes and opposite signs will have a zero electric potential because the contributions from the two charges will be equal in magnitude and opposite in sign. (Net electric potential is a *scalar* sum.) This point will not have a zero electric field, however, because the electric field contributions will be in the same direction (towards the negative and away from the positive) and so will add. (Net electric field is a *vector* sum.) As another example, consider the point exactly between two equal positive point charges. The electric potential will be positive since it is the sum of two positive numbers, but the electric field will be zero since the field contributions from the two charges will be equal in magnitude but opposite in direction.

7. (*a*) V at other points would be lower by 10 V. E would be unaffected, since E is the negative gradient of V, and a change in V by a constant value will not change the value of the gradient.
   (*b*) If V represents an absolute potential, then yes, the fact that the Earth carries a net charge would affect the value of V at the surface. If V represents a potential difference, then no, the net charge on the Earth would not affect the choice of V.

8. No. An equipotential line is a line connecting points of equal electric potential. If two equipotential lines crossed, it would indicate that their intersection point has two different values of electric potential simultaneously, which is impossible. As an analogy, imagine contour lines on a topographic map. They also never cross because one point on the surface of the Earth cannot have two different values for elevation above sea level.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9. The equipotential lines (in black) are perpendicular to the electric field lines (in red).

10. The electric field is zero in a region of space where the electric potential is constant. The electric field is the gradient of the potential; if the potential is constant, the gradient is zero.

11. The Earth's gravitational equipotential lines are roughly circular, so the orbit of the satellite would have to be roughly circular.

12. The potential at point P would be unchanged. Each bit of positive charge will contribute an amount to the potential based on its charge and its distance from point P. Moving charges to different locations on the ring does not change their distance from P, and hence does not change their contributions to the potential at P.

    The value of the electric field will change. The electric field is the vector sum of all the contributions to the field from the individual charges. When the charge Q is distributed uniformly about the ring, the y-components of the field contributions cancel, leaving a net field in the x-direction. When the charge is not distributed uniformly, the y-components will not cancel, and the net field will have both x- and y-components, and will be larger than for the case of the uniform charge distribution. There is no discrepancy here, because electric potential is a scalar and electric field is a vector.

13. The charge density and the electric field strength will be greatest at the pointed ends of the football because the surface there has a smaller radius of curvature than the middle.

14. No. You cannot calculate electric potential knowing only electric field at a point and you cannot calculate electric field knowing only electric potential at a point. As an example, consider the uniform field between two charged, conducting plates. If the potential difference between the plates is known, then the distance between the plates must also be known in order to calculate the field. If the field between the plates is known, then the distance to a point of interest between the plates must also be known in order to calculate the potential there. In general, to find V, you must know E and be able to integrate it. To find E, you must know V and be able to take its derivative. Thus you need E or V in the region around the point, not just at the point, in order to be able to find the other variable.

15. (*a*) Once the two spheres are placed in contact with each other, they effectively become one larger conductor. They will have the same potential because the potential everywhere on a conducting surface is constant.
    (*b*) Because the spheres are identical in size, an amount of charge $Q/2$ will flow from the initially charged sphere to the initially neutral sphere so that they will have equal charges.
    (*c*) Even if the spheres do not have the same radius, they will still be at the same potential once they are brought into contact because they still create one larger conductor. However, the amount of charge that flows will not be exactly equal to half the total charge. The larger sphere will end up with the larger charge.

16. If the electric field points due north, the change in the potential will be (*a*) greatest in the direction opposite the field, south; (*b*) least in the direction of the field, north; and (*c*) zero in a direction perpendicular to the field, east and west.

17. Yes. In regions of space where the equipotential lines are closely spaced, the electric field is stronger than in regions of space where the equipotential lines are farther apart.

18. If the electric field in a region of space is uniform, then you can infer that the electric potential is increasing or decreasing uniformly in that region. For example, if the electric field is 10 V/m in a region of space then you can infer that the potential difference between two points 1 meter apart (measured parallel to the direction of the field) is 10 V. If the electric potential in a region of space is uniform, then you can infer that the electric field there is zero.

19. The electric potential energy of two unlike charges is negative. The electric potential energy of two like charges is positive. In the case of unlike charges, work must be done to separate the charges. In the case of like charges, work must be done to move the charges together.

Solutions to Problems

1. Energy is conserved, so the change in potential energy is the opposite of the change in kinetic energy. The change in potential energy is related to the change in potential.

$$\Delta U = q\Delta V = -\Delta K \quad \rightarrow$$

$$\Delta V = \frac{-\Delta K}{q} = \frac{K_{\text{initial}} - K_{\text{final}}}{q} = \frac{mv^2}{2q} = \frac{\left(9.11\times10^{-31}\,\text{kg}\right)\left(5.0\times10^{5}\,\text{m/s}\right)^2}{2\left(-1.60\times10^{-19}\,\text{C}\right)} = \boxed{-0.71\,\text{V}}$$

The final potential should be lower than the initial potential in order to stop the electron.

2. The work done by the electric field can be found from Eq. 23-2b.

$$V_{\text{ba}} = -\frac{W_{\text{ba}}}{q} \quad \rightarrow \quad W_{\text{ba}} = -qV_{\text{ba}} = -\left(1.60\times10^{-19}\,\text{C}\right)\left[-55\,\text{V} - 185\,\text{V}\right] = \boxed{3.84\times10^{-17}\,\text{J}}$$

3. The kinetic energy gained by the electron is the work done by the electric force. Use Eq. 23-2b to calculate the potential difference.

$$V_{\text{ba}} = -\frac{W_{\text{ba}}}{q} = -\frac{5.25\times10^{-16}\,\text{J}}{\left(-1.60\times10^{-19}\,\text{C}\right)} = \boxed{3280\,\text{V}}$$

The electron moves from low potential to high potential, so $\boxed{\text{plate B}}$ is at the higher potential.

4. By the work energy theorem, the total work done, by the external force and the electric field together, is the change in kinetic energy. The work done by the electric field is given by Eq. 23-2b.

$$W_{\text{external}} + W_{\text{electric}} = \text{KE}_{\text{final}} - \text{KE}_{\text{initial}} \quad \rightarrow \quad W_{\text{external}} - q\left(V_{\text{b}} - V_{\text{a}}\right) = \text{KE}_{\text{final}} \quad \rightarrow$$

$$\left(V_{\text{b}} - V_{\text{a}}\right) = \frac{W_{\text{external}} - \text{KE}_{\text{final}}}{q} = \frac{7.00\times10^{-4}\,\text{J} - 2.10\times10^{-4}\,\text{J}}{-9.10\times10^{-6}\,\text{C}} = \boxed{-53.8\,\text{V}}$$

Since the potential difference is negative, we see that $V_{\text{a}} > V_{\text{b}}$.

5. As an estimate, the length of the bolt would be the voltage difference of the bolt divided by the breakdown electric field of air.

$$\frac{1\times10^{8}\,\text{V}}{3\times10^{6}\,\text{V/m}} = 33\,\text{m} \approx \boxed{30\,\text{m}}$$

6. The distance between the plates is found from Eq. 23-4b, using the magnitude of the electric field.

$$|E| = \frac{V_{\text{ba}}}{d} \quad \rightarrow \quad d = \frac{V_{\text{ba}}}{|E|} = \frac{45\,\text{V}}{1300\,\text{V/m}} = \boxed{3.5\times10^{-2}\,\text{m}}$$

7. The maximum charge will produce an electric field that causes breakdown in the air. We use the same approach as in Examples 23-4 and 23-5.

$$V_{\text{surface}} = r_0 E_{\text{breakdown}} \text{ and } V_{\text{surface}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r_0} \quad \rightarrow$$

$$Q = 4\pi\varepsilon_0 r_0^2 E_{\text{breakdown}} = \left(\frac{1}{8.99\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2}\right)(0.065\,\text{m})^2\left(3\times10^{6}\,\text{V/m}\right) = \boxed{1.4\times10^{-6}\,\text{C}}$$

8. We assume that the electric field is uniform, and so use Eq. 23-4b, using the magnitude of the electric field.

$$E = \frac{V_{\text{ba}}}{d} = \frac{110\,\text{V}}{4.0\times10^{-3}\,\text{m}} = \boxed{2.8\times10^{4}\,\text{V/m}}$$

9. To find the limiting value, we assume that the E-field at the radius of the sphere is the minimum value that will produce breakdown in air. We use the same approach as in Examples 23-4 and 23-5.

$$V_{\text{surface}} = r_0 E_{\text{breakdown}} \quad \rightarrow \quad r_0 = \frac{V_{\text{surface}}}{E_{\text{breakdown}}} = \frac{35{,}000\,\text{V}}{3\times10^{6}\,\text{V/m}} = 0.0117\,\text{m} \approx \boxed{0.012\,\text{m}}$$

$$V_{\text{surface}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r_0} \quad \rightarrow \quad Q = 4\pi\varepsilon_0 V_{\text{surface}} r_0 = \left(\frac{1}{8.99\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2}\right)(35{,}000\,\text{V})(0.0117\,\text{m})$$

$$= \boxed{4.6\times10^{-8}\,\text{C}}$$

10. If we assume the electric field is uniform, then we can use Eq. 23-4b to estimate the magnitude of the electric field. From Problem 22-24 we have an expression for the electric field due to a pair of oppositely charged planes. We approximate the area of a shoe as 30 cm x 8 cm.

$$E = \frac{V}{d} = \frac{\sigma}{\varepsilon_0} = \frac{Q}{\varepsilon_0 A} \quad \rightarrow$$

$$Q = \frac{\varepsilon_0 A V}{d} = \frac{\left(8.85\times10^{-12}\,\text{C}^2/\text{Nm}^2\right)\left(0.024\,\text{m}^2\right)\left(5.0\times10^{3}\,\text{V}\right)}{1.0\times10^{-3}\,\text{m}} = \boxed{1.1\times10^{-6}\,\text{C}}$$

11. Since the field is uniform, we may apply Eq. 23-4b. Note that the electric field always points from high potential to low potential.

(*a*) $\boxed{V_{\text{BA}} = 0}$. The distance between the two points is exactly perpendicular to the field lines.

(*b*) $V_{\text{CB}} = V_{\text{C}} - V_{\text{B}} = \left(-4.20\,\text{N/C}\right)\left(7.00\,\text{m}\right) = \boxed{-29.4\,\text{V}}$

(*c*) $V_{\text{CA}} = V_{\text{C}} - V_{\text{A}} = V_{\text{C}} - V_{\text{B}} + V_{\text{B}} - V_{\text{A}} = V_{\text{CB}} + V_{\text{BA}} = -29.4\,\text{V} + 0 = \boxed{-29.4\,\text{V}}$

12. From Example 22-7, the electric field produced by a large plate is uniform with magnitude $E = \dfrac{\sigma}{2\varepsilon_0}$.

The field points away from the plate, assuming that the charge is positive. Apply Eq. 23-41.

$$V(x) - V(0) = V(x) - V_0 = -\int_0^x \vec{\mathbf{E}} \bullet \left(d\vec{\boldsymbol{\ell}}\right) = -\int_0^x \left(\frac{\sigma}{2\varepsilon_0}\hat{\mathbf{i}}\right) \bullet \left(dx\hat{\mathbf{i}}\right) = -\frac{\sigma x}{2\varepsilon_0} \quad \rightarrow \quad \boxed{V(x) = V_0 - \frac{\sigma x}{2\varepsilon_0}}$$

13. (*a*) The electric field at the surface of the Earth is the same as that of a point charge, $E = \dfrac{Q}{4\pi\varepsilon_0 r_0^2}$.

The electric potential at the surface, relative to $V(\infty) = 0$ is given by Eq. 23-5. Writing this in terms of the electric field and radius of the earth gives the electric potential.

$$V = \frac{Q}{4\pi\varepsilon_0 r_0} = Er_0 = \left(-150\,\text{V/m}\right)\left(6.38\times10^6\,\text{m}\right) = \boxed{-0.96\ \text{GV}}$$

(*b*) Part (*a*) demonstrated that the potential at the surface of the earth is 0.96 GV lower than the potential at infinity. Therefore if the potential at the surface of the Earth is taken to be zero, the potential at infinity must be $V(\infty) = \boxed{0.96\ \text{GV}}$. If the charge of the ionosphere is included in the calculation, the electric field outside the ionosphere is basically zero. The electric field between the earth and the ionosphere would remain the same. The electric potential, which would be the integral of the electric field from infinity to the surface of the earth, would reduce to the integral of the electric field from the ionosphere to the earth. This would result in a negative potential, but of a smaller magnitude.

14. (*a*) The potential at the surface of a charged sphere is derived in Example 23-4.

$$V_0 = \frac{Q}{4\pi\varepsilon_0 r_0} \quad \rightarrow \quad Q = 4\pi\varepsilon_0 r_0 V_0 \quad \rightarrow$$

$$\sigma = \frac{Q}{\text{Area}} = \frac{Q}{4\pi r_0^2} = \frac{4\pi\varepsilon_0 r_0 V_0}{4\pi r_0^2} = \frac{V_0\varepsilon_0}{r_0} = \frac{\left(680\,\text{V}\right)\left(8.85\times10^{-12}\ \text{C}^2/\text{Nm}^2\right)}{\left(0.16\,\text{m}\right)} = 3.761\times10^{-8}\,\text{C/m}^2$$

$$\approx \boxed{3.8\times10^{-8}\,\text{C/m}^2}$$

(*b*) The potential away from the surface of a charged sphere is also derived in Example 23-4.

$$V = \frac{Q}{4\pi\varepsilon_0 r} = \frac{4\pi\varepsilon_0 r_0 V_0}{4\pi\varepsilon_0 r} = \frac{r_0 V_0}{r} \quad \rightarrow \quad r = \frac{r_0 V_0}{V} = \frac{\left(0.16\,\text{m}\right)\left(680\,\text{V}\right)}{\left(25\,\text{V}\right)} = 4.352\,\text{m} \approx \boxed{4.4\,\text{m}}$$

15. (*a*) After the connection, the two spheres are at the same potential. If they were at different potentials, then there would be a flow of charge in the wire until the potentials were equalized.

(*b*) We assume the spheres are so far apart that the charge on one sphere does not influence the charge on the other sphere. Another way to express this would be to say that the potential due to either of the spheres is zero at the location of the other sphere. The charge splits between the spheres so that their potentials (due to the charge on them only) are equal. The initial charge on sphere 1 is Q, and the final charge on sphere 1 is Q_1.

$$V_1 = \frac{Q_1}{4\pi\varepsilon_0 r_1} \ ; \ V_2 = \frac{Q - Q_1}{4\pi\varepsilon_0 r_2} \ ; \ V_1 = V_2 \quad \rightarrow \quad \frac{Q_1}{4\pi\varepsilon_0 r_1} = \frac{Q - Q_1}{4\pi\varepsilon_0 r_2} \quad \rightarrow \quad Q_1 = Q\frac{r_1}{\left(r_1 + r_2\right)}$$

Charge transferred $Q - Q_1 = Q - Q\dfrac{r_1}{\left(r_1 + r_2\right)} = \boxed{Q\dfrac{r_2}{\left(r_1 + r_2\right)}}$

16. From Example 22-6, the electric field due to a long wire is radial relative to the wire, and is of magnitude $E = \dfrac{1}{2\pi\varepsilon_0}\dfrac{\lambda}{R}$. If the charge density is positive, the field lines point radially away from the wire. Use Eq. 23-41 to find the potential difference, integrating along a line that is radially outward from the wire.

$$V_\text{b} - V_\text{a} = -\int_{R_\text{a}}^{R_\text{b}} \vec{\mathbf{E}}\bullet\left(d\vec{\boldsymbol{\ell}}\right) = -\int_{R_\text{a}}^{R_\text{b}} \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{R}\,dR = -\frac{\lambda}{2\pi\varepsilon_0}\ln\left(R_\text{b} - R_\text{a}\right) = \boxed{\frac{\lambda}{2\pi\varepsilon_0}\ln\frac{R_\text{a}}{\text{R}_\text{b}}}$$

17. (*a*) The width of the end of a finger is about 1 cm, and so consider the fingertip to be a part of a sphere of diameter 1 cm. We assume that the electric field at the radius of the sphere is the minimum value that will produce breakdown in air. We use the same approach as in Examples 23-4 and 23-5.

$$V_\text{surface} = r_0 E_\text{breakdown} = \left(0.005\,\text{m}\right)\left(3\times10^6\ \text{V/m}\right) = \boxed{15{,}000\,\text{V}}$$

Since this is just an estimate, we might expect anywhere from 10,000 V to 20,000 V.

(*b*) $V_\text{surface} = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{r_0} = \dfrac{1}{4\pi\varepsilon_0}\dfrac{4\pi r_0^2\sigma}{r_0} \quad \rightarrow$

$$\sigma = V_\text{surface}\frac{\varepsilon_0}{r_0} = \left(15{,}000\,\text{V}\right)\frac{\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\bullet\text{m}^2\right)}{0.005\,\text{m}} = \boxed{2.7\times10^{-5}\,\text{C/m}^2}$$

Since this is an estimate, we might say the charge density is on the order of $30\,\mu\text{C/m}^2$.

18. We assume the field is uniform, and so Eq. 23-4b applies.

$$E = \frac{V}{d} = \frac{0.10\,\text{V}}{10\times10^{-9}\,\text{m}} = \boxed{1\times10^7\ \text{V/m}}$$

19. (*a*) The electric field outside a charged, spherically symmetric volume is the same as that for a point charge of the same magnitude of charge. Integrating the electric field from infinity to the radius of interest will give the potential at that radius.

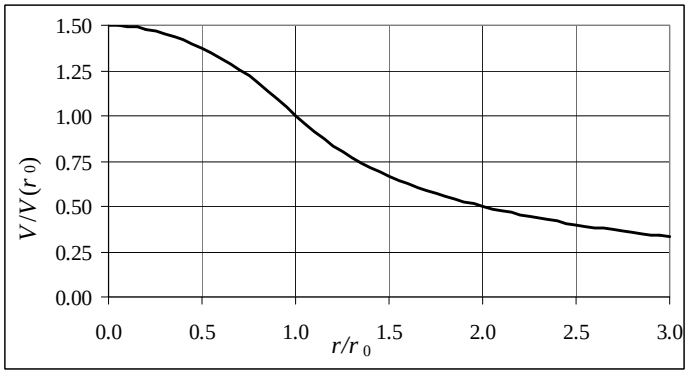
$$E\left(r \ge r_0\right) = \frac{Q}{4\pi\varepsilon_0 r^2} \ ;\ V\left(r \ge r_0\right) = -\int_\infty^r \frac{Q}{4\pi\varepsilon_0 r^2}\,dr = \frac{Q}{4\pi\varepsilon_0 r}\bigg|_\infty^r = \boxed{\frac{Q}{4\pi\varepsilon_0 r}}$$

(*b*) Inside the sphere the electric field is obtained from Gauss's Law using the charge enclosed by a sphere of radius *r*.

$$4\pi r^2 E = \frac{Q}{\varepsilon_0}\frac{\frac{4}{3}\pi r^3}{\frac{4}{3}\pi r_0^3} \quad \rightarrow \quad E\left(r < r_0\right) = \frac{Qr}{4\pi\varepsilon_0 r_0^3}$$

Integrating the electric field from the surface to $r < r_0$ gives the electric potential inside the sphere.

$$V\left(r < r_0\right) = V\left(r_0\right) - \int_{r_0}^r \frac{Qr}{4\pi\varepsilon_0 r_0^3}\,dr = \frac{Q}{4\pi\varepsilon_0 r_0} - \frac{Qr^2}{8\pi\varepsilon_0 r_0^3}\bigg|_{r_0}^r = \boxed{\frac{Q}{8\pi\varepsilon_0 r_0}\left(3 - \frac{r^2}{r_0^2}\right)}$$



(*c*) To plot, we first calculate $V_0 = V\left(r = r_0\right) = \dfrac{Q}{4\pi\varepsilon_0 r_0}$ and $E_0 = E\left(r = r_0\right) = \dfrac{Q}{4\pi\varepsilon_0 r_0^2}$. Then we plot V/V_0 and E/E_0 as functions of r/r_0.

For $r < r_0$: $\quad V/V_0 = \dfrac{\dfrac{Q}{8\pi\varepsilon_0 r_0}\left(3 - \dfrac{r^2}{r_0^2}\right)}{\dfrac{Q}{4\pi\varepsilon_0 r_0}} = \tfrac{1}{2}\left(3 - \dfrac{r^2}{r_0^2}\right)$; $E/E_0 = \dfrac{\dfrac{Qr}{4\pi\varepsilon_0 r_0^3}}{\dfrac{Q}{4\pi\varepsilon_0 r_0^2}} = \dfrac{r}{r_0}$

For $r > r_0$: $\quad V/V_0 = \dfrac{\dfrac{Q}{4\pi\varepsilon_0 r}}{\dfrac{Q}{4\pi\varepsilon_0 r_0}} = \dfrac{r_0}{r} = (r/r_0)^{-1}$; $E/E_0 = \dfrac{\dfrac{Q}{4\pi\varepsilon_0 r^2}}{\dfrac{Q}{4\pi\varepsilon_0 r_0^2}} = \dfrac{r_0^2}{r^2} = (r/r_0)^{-2}$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH23.XLS," on tab "Problem 23.19c."

20. We assume the total charge is still Q, and let $\rho_E = kr^2$. We evaluate the constant k by calculating the total charge, in the manner of Example 22-5.

$$Q = \int \rho_E dV = \int_0^{r_0} kr^2\left(4\pi r^2 dr\right) = \tfrac{4}{5}k\pi r_0^5 \quad \rightarrow \quad k = \frac{5Q}{4\pi r_0^5}$$

(*a*) The electric field outside a charged, spherically symmetric volume is the same as that for a point charge of the same magnitude of charge. Integrating the electric field from infinity to the radius of interest gives the potential at that radius.

$$E\left(r \geq r_0\right) = \frac{Q}{4\pi\varepsilon_0 r^2} \quad ; \quad V\left(r \geq r_0\right) = -\int_\infty^r \frac{Q}{4\pi\varepsilon_0 r^2}dr = \frac{Q}{4\pi\varepsilon_0 r}\bigg|_\infty^r = \boxed{\frac{Q}{4\pi\varepsilon_0 r}}$$

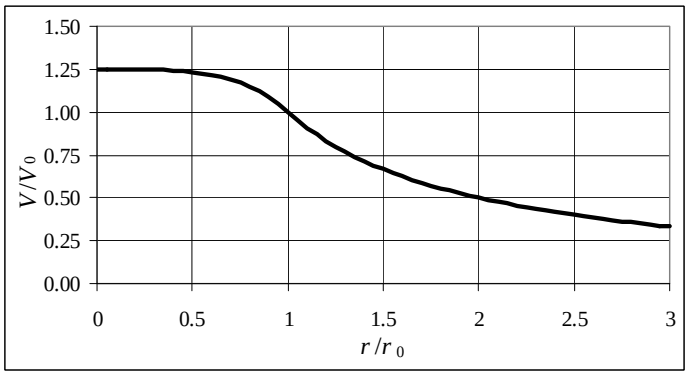
(*b*) Inside the sphere the electric field is obtained from Gauss's Law using the charge enclosed by a sphere of radius r.

$$4\pi r^2 E = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad ; \quad Q_{\text{encl}} = \int \rho_E dV = \frac{5Q}{4\pi r_0^5}\int_0^r r^2\left(4\pi r^2 dr\right) = \frac{5Q}{4\pi r_0^5}\tfrac{4}{5}\pi r^5 = \frac{Qr^5}{r_0^5} \quad \rightarrow$$

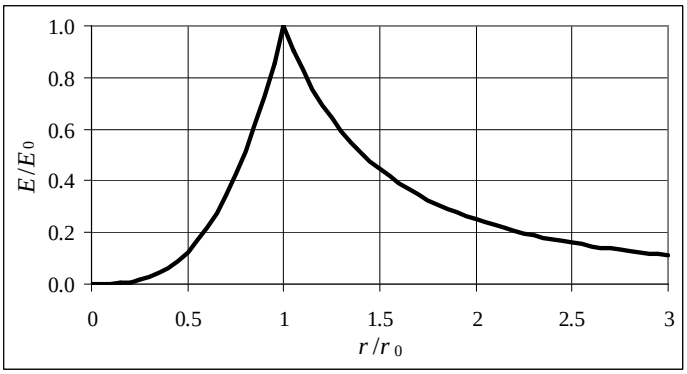
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E\left(r<r_0\right)=\frac{Q_{\text{encl}}}{4\pi\varepsilon_0 r^2}=\frac{Qr^3}{4\pi\varepsilon_0 r_0^5}$$

Integrating the electric field from the surface to $r<r_0$ gives the electric potential inside the sphere.



$$V\left(r<r_0\right)=V\left(r_0\right)-\int_{r_0}^{r}\frac{Qr^3}{4\pi\varepsilon_0 r_0^5}dr=\frac{Q}{4\pi\varepsilon_0 r_0}-\left.\frac{Qr^4}{16\pi\varepsilon_0 r_0^5}\right|_{r_0}^{r}=\frac{Q}{16\pi\varepsilon_0 r_0}\left(5-\frac{r^4}{r_0^4}\right)$$



(*c*) To plot, we first calculate $V_0=V\left(r=r_0\right)=\dfrac{Q}{4\pi\varepsilon_0 r_0}$ and $E_0=E\left(r=r_0\right)=\dfrac{Q}{4\pi\varepsilon_0 r_0^2}$. Then we plot V/V_0 and E/E_0 as functions of r/r_0.

For $r<r_0$: $\quad V/V_0=\dfrac{\dfrac{Q}{16\pi\varepsilon_0 r_0}\left(5-\dfrac{r^4}{r_0^4}\right)}{\dfrac{Q}{4\pi\varepsilon_0 r_0}}=\frac{1}{4}\left(5-\dfrac{r^4}{r_0^4}\right)$; $E/E_0=\dfrac{\dfrac{Qr^3}{4\pi\varepsilon_0 r_0^5}}{\dfrac{Q}{4\pi\varepsilon_0 r_0^2}}=\dfrac{r^3}{r_0^3}$

For $r>r_0$: $\quad V/V_0=\dfrac{\dfrac{Q}{4\pi\varepsilon_0 r}}{\dfrac{Q}{4\pi\varepsilon_0 r_0}}=\dfrac{r_0}{r}=\left(r/r_0\right)^{-1}$; $E/E_0=\dfrac{\dfrac{Q}{4\pi\varepsilon_0 r^2}}{\dfrac{Q}{4\pi\varepsilon_0 r_0^2}}=\dfrac{r_0^2}{r^2}=\left(r/r_0\right)^{-2}$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH23.XLS," on tab "Problem 23.20c."

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21. We first need to find the electric field. Since the charge distribution is spherically symmetric, Gauss's law tells us the electric field everywhere.

$$\oint \vec{\mathbf{E}} \bullet d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad \rightarrow \quad E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2}$$

If $r < r_0$, calculate the charge enclosed in the manner of Example 22-5.

$$Q_{\text{encl}} = \int \rho_{\text{E}} dV = \int_0^r \rho_0 \left[1 - \frac{r^2}{r_0^2}\right] 4\pi r^2 dr = 4\pi\rho_0 \int_0^r \left[r^2 - \frac{r^4}{r_0^2}\right] dr = 4\pi\rho_0 \left[\frac{r^3}{3} - \frac{r^5}{5r_0^2}\right]$$

The total charge in the sphere is the above expression evaluated at $r = r_0$.

$$Q_{\text{total}} = 4\pi\rho_0 \left[\frac{r_0^3}{3} - \frac{r_0^5}{5r_0^2}\right] = \frac{8\pi\rho_0 r_0^3}{15}$$

Outside the sphere, we may treat it as a point charge, and so the potential at the surface of the sphere is given by Eq. 23-5, evaluated at the surface of the sphere.

$$V\left(r = r_0\right) = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{total}}}{r_0} = \frac{1}{4\pi\varepsilon_0}\frac{\frac{8\pi\rho_0 r_0^3}{15}}{r_0} = \frac{2\rho_0 r_0^2}{15\varepsilon_0}$$

The potential inside is found from Eq. 23-4a. We need the field inside the sphere to use Eq. 23-4a. The field is radial, so we integrate along a radial line so that $\vec{\mathbf{E}} \bullet d\vec{\boldsymbol{\ell}} = E dr$.

$$E\left(r < r_0\right) = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{4\pi\rho_0\left[\frac{r^3}{3} - \frac{r^5}{5r_0^2}\right]}{r^2} = \frac{\rho_0}{\varepsilon_0}\left[\frac{r}{3} - \frac{r^3}{5r_0^2}\right]$$

$$V_r - V_{r_0} = -\int_{r_0}^r \vec{\mathbf{E}} \bullet d\vec{\boldsymbol{\ell}} = -\int_{r_0}^r E\, dr = -\int_{r_0}^r \frac{\rho_0}{\varepsilon_0}\left[\frac{r}{3} - \frac{r^3}{5r_0^2}\right] dr = -\frac{\rho_0}{\varepsilon_0}\left[\frac{r^2}{6} - \frac{r^4}{20r_0^2}\right]_{r_0}^r$$

$$V_r = V_{r_0} + \left(-\frac{\rho_0}{\varepsilon_0}\left[\frac{r^2}{6} - \frac{r^4}{20r_0^2}\right]_{r_0}^r\right) = \frac{2\rho_0 r_0^2}{15\varepsilon_0} - \frac{\rho_0}{\varepsilon_0}\left[\left(\frac{r^2}{6} - \frac{r^4}{20r_0^2}\right) - \left(\frac{r_0^2}{6} - \frac{r_0^4}{20r_0^2}\right)\right]$$

$$= \boxed{\frac{\rho_0}{\varepsilon_0}\left(\frac{r_0^2}{4} - \frac{r^2}{6} + \frac{r^4}{20r_0^2}\right)}$$

22. Because of the spherical symmetry of the problem, the electric field in each region is the same as that of a point charge equal to the net enclosed charge.

(*a*) For $r > r_2$: $E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{\frac{3}{2}Q}{r^2} = \boxed{\frac{3}{8\pi\varepsilon_0}\frac{Q}{r^2}}$

For $r_1 < r < r_2$: $E = \boxed{0}$, because the electric field is 0 inside of conducting material.

For $0 < r < r_1$: $E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{\frac{1}{2}Q}{r^2} = \boxed{\frac{1}{8\pi\varepsilon_0}\frac{Q}{r^2}}$

(*b*) For $r > r_2$, the potential is that of a point charge at the center of the sphere.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r} = \frac{1}{4\pi\varepsilon_0}\frac{\frac{3}{2}Q}{r} = \boxed{\frac{3}{8\pi\varepsilon_0}\frac{Q}{r}}, \; r > r_2$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

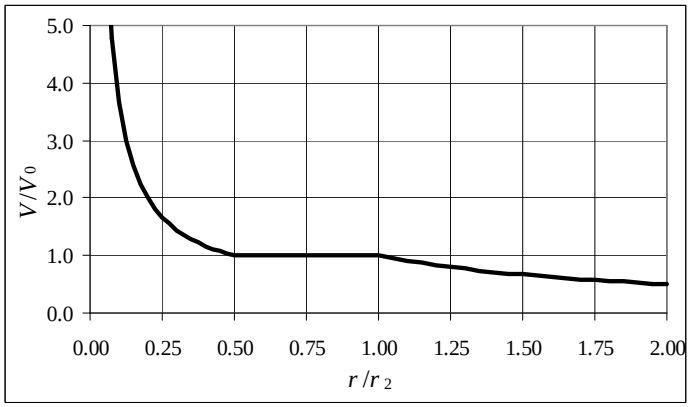
(*c*) For $r_1 < r < r_2$, the potential is constant and equal to its value on the outer shell, because there is no electric field inside the conducting material.

$$V = V\left(r = r_2\right) = \boxed{\frac{3}{8\pi\varepsilon_0}\frac{Q}{r_2}}, \; r_1 < r < r_2$$

(*d*) For $0 < r < r_1$, we use Eq. 23-4a. The field is radial, so we integrate along a radial line so that $\vec{\mathbf{E}} \bullet d\vec{\boldsymbol{\ell}} = E dr$.

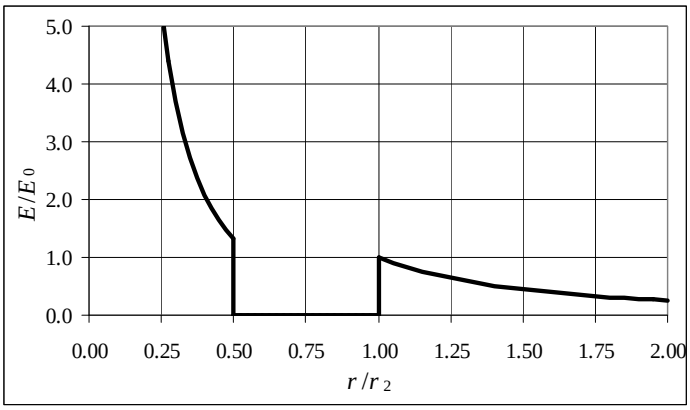
$$V_r - V_{r_1} = -\int_{r_1}^{r} \vec{\mathbf{E}} \bullet d\vec{\boldsymbol{\ell}} = -\int_{r_1}^{r} E\, dr = -\int_{r_1}^{r} \frac{1}{8\pi\varepsilon_0}\frac{Q}{r^2} dr = \frac{Q}{8\pi\varepsilon_0}\left(\frac{1}{r} - \frac{1}{r_1}\right)$$

$$V_r = V_{r_1} + \frac{Q}{8\pi\varepsilon_0}\left(\frac{1}{r} - \frac{1}{r_1}\right) = \frac{Q}{8\pi\varepsilon_0}\left(\frac{1}{2r_1} + \frac{1}{r}\right) = \boxed{\frac{Q}{8\pi\varepsilon_0}\left(\frac{1}{r_2} + \frac{1}{r}\right)}, \; 0 < r < r_1$$



(*e*) To plot, we first calculate $V_0 = V\left(r = r_2\right) = \dfrac{3Q}{8\pi\varepsilon_0 r_2}$ and $E_0 = E\left(r = r_2\right) = \dfrac{3Q}{8\pi\varepsilon_0 r_2^2}$. Then we plot V/V_0 and E/E_0 as functions of r/r_2.

For $0 < r < r_1$: $\dfrac{V}{V_0} = \dfrac{\dfrac{Q}{8\pi\varepsilon_0}\left(\dfrac{1}{r_2} + \dfrac{1}{r}\right)}{\dfrac{3Q}{8\pi\varepsilon_0 r_2}} = \frac{1}{3}\left[1 + \left(r/r_2\right)^{-1}\right]$; $\dfrac{E}{E_0} = \dfrac{\dfrac{1}{8\pi\varepsilon_0}\dfrac{Q}{r^2}}{\dfrac{3Q}{8\pi\varepsilon_0 r_2^2}} = \frac{1}{3}\dfrac{r_2^2}{r^2} = \frac{1}{3}\left(r/r_2\right)^{-2}$



For $r_1 < r < r_2$: $\dfrac{V}{V_0} = \dfrac{\dfrac{3}{8\pi\varepsilon_0}\dfrac{Q}{r_2}}{\dfrac{3Q}{8\pi\varepsilon_0 r_2}} = 1$; $\dfrac{E}{E_0} = \dfrac{0}{\dfrac{3Q}{8\pi\varepsilon_0 r_2^2}} = 0$

For $r > r_2$: $\dfrac{V}{V_0} = \dfrac{\dfrac{3}{8\pi\varepsilon_0}\dfrac{Q}{r}}{\dfrac{3Q}{8\pi\varepsilon_0 r_2}} = \dfrac{r_2}{r} = \left(r/r_2\right)^{-1}$; $\dfrac{E}{E_0} = \dfrac{\dfrac{3}{8\pi\varepsilon_0}\dfrac{Q}{r^2}}{\dfrac{3Q}{8\pi\varepsilon_0 r_2^2}} = \dfrac{r_2^2}{r^2} = \left(r/r_2\right)^{-2}$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH23.XLS," on tab "Problem 23.22e."

23. The field is found in Problem 22-33. The field inside the cylinder is 0, and the field outside the cylinder is $\dfrac{\sigma R_0}{\varepsilon_0 R}$.

(*a*) Use Eq. 23-4a to find the potential. Integrate along a radial line, so that $\vec{\mathbf{E}}\bullet d\vec{\boldsymbol{\ell}} = E\,dR$.

$$V_R - V_{R_0} = -\int_{R_0}^{R} \vec{\mathbf{E}}\bullet d\vec{\boldsymbol{\ell}} = -\int_{R_0}^{R} E\,dR = -\int_{R_0}^{R} \frac{\sigma R_0}{\varepsilon_0 R}\,dR = -\frac{\sigma R_0}{\varepsilon_0}\ln\frac{R}{R_0} \quad \rightarrow$$

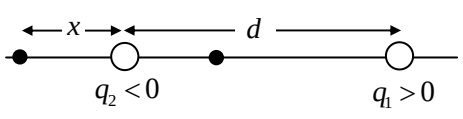
$$V_R = \boxed{V_0 - \frac{\sigma R_0}{\varepsilon_0}\ln\frac{R}{R_0}},\ R > R_0$$

(*b*) The electric field inside the cylinder is 0, so the potential inside is constant and equal to the potential on the surface, $\boxed{V_0}$.

(*c*) No, we are not able to assume that $V = 0$ at $R = \infty$. $V \neq 0$ because there would be charge at infinity for an infinite cylinder. And from the formula derived in (*a*), if $R = \infty$, $V_R = -\infty$.

24. Use Eq. 23-5 to find the charge.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r} \rightarrow Q = (4\pi\varepsilon_0)rV = \left(\frac{1}{8.99\times10^9\ \text{N}\bullet\text{m}^2/\text{C}^2}\right)(0.15\ \text{m})(185\ \text{V}) = \boxed{3.1\times10^{-9}\ \text{C}}$$



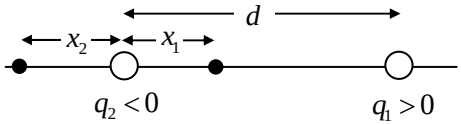
25. (*a*) The electric potential is given by Eq. 23-5.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r} = \left(8.99\times10^9\ \text{N}\bullet\text{m}^2/\text{C}^2\right)\frac{1.60\times10^{-19}\ \text{C}}{0.50\times10^{-10}\ \text{m}} = 28.77\ \text{V} \approx \boxed{29\ \text{V}}$$

(*b*) The potential energy of the electron is the charge of the electron times the electric potential due to the proton.

$$U = QV = \left(-1.60\times10^{-19}\ \text{C}\right)(28.77\ \text{V}) = \boxed{-4.6\times10^{-18}\ \text{J}}$$

26. (*a*) Because of the inverse square nature of the electric field, any location where the field is zero must be closer to the weaker charge (q_2). Also, in between the two charges, the fields due to the two charges are parallel to each other (both to the left) and cannot cancel. Thus the only places where the field can be zero are closer to the weaker charge,



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

but not between them. In the diagram, this is the point to the left of q_2. Take rightward as the positive direction.

$$E = \frac{1}{4\pi\varepsilon_0}\frac{|q_2|}{x^2} - \frac{1}{4\pi\varepsilon_0}\frac{q_1}{(d+x)^2} = 0 \;\rightarrow\; |q_2|(d+x)^2 = q_1 x^2 \;\rightarrow$$

$$x = \frac{\sqrt{|q_2|}}{\sqrt{q_1}-\sqrt{|q_2|}}d = \frac{\sqrt{2.0\times10^{-6}\,\text{C}}}{\sqrt{3.4\times10^{-6}\,\text{C}}-\sqrt{2.0\times10^{-6}\,\text{C}}}(5.0\,\text{cm}) = \boxed{16\,\text{cm left of } q_2}$$

(*b*) The potential due to the positive charge is positive everywhere, and the potential due to the negative charge is negative everywhere. Since the negative charge is smaller in magnitude than the positive charge, any point where the potential is zero must be closer to the negative charge. So consider locations between the charges (position x_1) and to the left of the negative charge (position x_2) as shown in the diagram.

$$V_{\text{location 1}} = \frac{1}{4\pi\varepsilon_0}\left[\frac{q_1}{(d-x_1)} + \frac{q_2}{x_1}\right] = 0 \;\rightarrow\; x_1 = \frac{q_2 d}{(q_2-q_1)} = \frac{(-2.0\times10^{-6}\,\text{C})(5.0\,\text{cm})}{(-5.4\times10^{-6}\,\text{C})} = 1.852\,\text{cm}$$

$$V_{\text{location 2}} = \frac{1}{4\pi\varepsilon_0}\left[\frac{q_1}{(d+x_2)} + \frac{q_2}{x_2}\right] = 0 \;\rightarrow$$

$$x_2 = -\frac{q_2 d}{(q_1+q_2)} = -\frac{(-2.0\times10^{-6}\,\text{C})(5.0\,\text{cm})}{(1.4\times10^{-6}\,\text{C})} = 7.143\,\text{cm}$$

So the two locations where the potential is zero are 1.9 cm from the negative charge towards the positive charge, and 7.1 cm from the negative charge away from the positive charge.

27. The work required is the difference in the potential energy of the charges, calculated with the test charge at the two different locations. The potential energy of a pair of charges is given in Eq. 23-10 as $U = \frac{1}{4\pi\varepsilon_0}\frac{qQ}{r}$. So to find the work, calculate the difference in potential energy with the test charge at the two locations. Let *Q* represent the $25\mu\text{C}$ charge, let *q* represent the $0.18\mu\text{C}$ test charge, *D* represent the 6.0 cm distance, and let *d* represent the 1.0 cm distance. Since the potential energy of the two $25\mu\text{C}$ charges doesn't change, we don't include it in the calculation.

$$U_{\text{initial}} = \frac{1}{4\pi\varepsilon_0}\frac{Qq}{D/2} + \frac{1}{4\pi\varepsilon_0}\frac{Qq}{D/2} \qquad U_{\text{final}} = \frac{1}{4\pi\varepsilon_0}\frac{Qq}{[D/2-d]} + \frac{1}{4\pi\varepsilon_0}\frac{Qq}{[D/2+d]}$$

$$\text{Work}_{\substack{\text{external}\\\text{force}}} = U_{\text{final}} - U_{\text{initial}} = \frac{1}{4\pi\varepsilon_0}\frac{Qq}{[D/2-d]} + \frac{1}{4\pi\varepsilon_0}\frac{Qq}{[D/2+d]} - 2\left(\frac{1}{4\pi\varepsilon_0}\frac{Qq}{D/2}\right)$$

$$= \frac{2Qq}{4\pi\varepsilon_0}\left[\frac{1}{[D-2d]} + \frac{1}{[D+2d]} - \frac{1}{D/2}\right]$$

$$= 2\left(8.99\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\left(25\times10^{-6}\,\text{C}\right)\left(0.18\times10^{-6}\,\text{C}\right)\left[\frac{1}{0.040\,\text{m}} + \frac{1}{0.080\,\text{m}} - \frac{1}{0.030\,\text{m}}\right]$$

$$= \boxed{0.34\,\text{J}}$$

An external force needs to do positive work to move the charge.

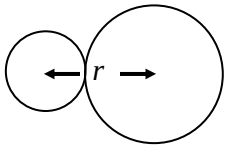
28. (*a*) The potential due to a point charge is given by Eq. 23-5.

$$V_{ba} = V_b - V_a = \frac{1}{4\pi\varepsilon_0}\frac{q}{r_b} - \frac{1}{4\pi\varepsilon_0}\frac{q}{r_a} = \frac{q}{4\pi\varepsilon_0}\left(\frac{1}{r_b} - \frac{1}{r_a}\right)$$

$$= \left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(-3.8\times10^{-6}\text{C}\right)\left(\frac{1}{0.36\,\text{m}} - \frac{1}{0.26\,\text{m}}\right) = \boxed{3.6\times10^4\,\text{V}}$$

(*b*) The magnitude of the electric field due to a point charge is given by Eq. 21-4a. The direction of the electric field due to a negative charge is towards the charge, so the field at point a will point downward, and the field at point b will point to the right. See the vector diagram.

$$\vec{\mathbf{E}}_b = \frac{1}{4\pi\varepsilon_0}\frac{|q|}{r_b^2}\hat{\mathbf{i}} = \frac{\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.8\times10^{-6}\text{C}\right)}{\left(0.36\,\text{m}\right)^2}\hat{\mathbf{i}} = 2.636\times10^5\ \text{V/m}\,\hat{\mathbf{i}}$$



$$\vec{\mathbf{E}}_a = -\frac{1}{4\pi\varepsilon_0}\frac{|q|}{r_a^2}\hat{\mathbf{j}} = -\frac{\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.8\times10^{-6}\text{C}\right)}{\left(0.26\,\text{m}\right)^2}\hat{\mathbf{j}} = -5.054\times10^5\ \text{V/m}\,\hat{\mathbf{j}}$$

$$\vec{\mathbf{E}}_b - \vec{\mathbf{E}}_a = 2.636\times10^5\ \text{V/m}\,\hat{\mathbf{i}} + 5.054\times10^5\ \text{V/m}\,\hat{\mathbf{j}}$$

$$\left|\vec{\mathbf{E}}_b - \vec{\mathbf{E}}_a\right| = \sqrt{\left(2.636\times10^5\ \text{V/m}\right)^2 + \left(5.054\times10^5\ \text{V/m}\right)^2} = \boxed{5.7\times10^5\ \text{V/m}}$$

$$\theta = \tan^{-1}\frac{-E_a}{E_b} = \tan^{-1}\frac{5.054\times10^5}{2.636\times10^5} = \boxed{62°}$$

29. We assume that all of the energy the proton gains in being accelerated by the voltage is changed to potential energy just as the proton's outer edge reaches the outer radius of the silicon nucleus.

$$U_{\text{initial}} = U_{\text{final}} \quad\rightarrow\quad eV_{\text{initial}} = \frac{1}{4\pi\varepsilon_0}\frac{e(14e)}{r} \quad\rightarrow$$

$$V_{\text{initial}} = \frac{1}{4\pi\varepsilon_0}\frac{14e}{r} = \left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(14)\left(1.60\times10^{-19}\text{C}\right)}{(1.2+3.6)\times10^{-15}\text{m}} = \boxed{4.2\times10^6\,\text{V}}$$

30. By energy conservation, all of the initial potential energy of the charges will change to kinetic energy when the charges are very far away from each other. By momentum conservation, since the initial momentum is zero and the charges have identical masses, the charges will have equal speeds in opposite directions from each other as they move. Thus each charge will have the same kinetic energy.

$$E_{\text{initial}} = E_{\text{final}} \quad\rightarrow\quad U_{\text{initial}} = K_{\text{final}} \quad\rightarrow\quad \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{r} = 2\left(\tfrac{1}{2}mv^2\right) \quad\rightarrow$$

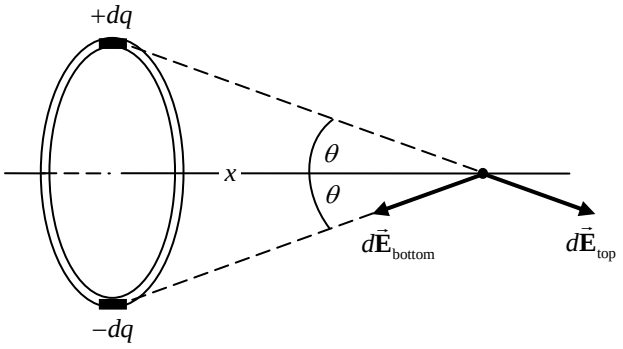
$$v = \sqrt{\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{mr}} = \sqrt{\frac{\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(5.5\times10^{-6}\text{C}\right)^2}{\left(1.0\times10^{-6}\text{kg}\right)\left(0.065\,\text{m}\right)}} = \boxed{2.0\times10^3\,\text{m/s}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31. By energy conservation, all of the initial potential energy will change to kinetic energy of the electron when the electron is far away. The other charge is fixed, and so has no kinetic energy. When the electron is far away, there is no potential energy.

$$E_{\text{initial}} = E_{\text{final}} \;\rightarrow\; U_{\text{initial}} = K_{\text{final}} \;\rightarrow\; \frac{(-e)(Q)}{4\pi\varepsilon_0 r} = \tfrac{1}{2}mv^2 \;\rightarrow$$

$$v = \sqrt{\frac{2(-e)(Q)}{(4\pi\varepsilon_0)mr}} = \sqrt{\frac{2\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(-1.60\times10^{-19}\,\text{C}\right)\left(-1.25\times10^{-10}\,\text{C}\right)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(0.425\,\text{m}\right)}}$$



$$= \boxed{9.64\times10^5\ \text{m/s}}$$

32. Use Eq. 23-2b and Eq. 23-5.

$$V_{\text{BA}} = V_{\text{B}} - V_{\text{A}} = \left(\frac{1}{4\pi\varepsilon_0}\frac{q}{d-b} + \frac{1}{4\pi\varepsilon_0}\frac{(-q)}{b}\right) - \left(\frac{1}{4\pi\varepsilon_0}\frac{q}{b} + \frac{1}{4\pi\varepsilon_0}\frac{(-q)}{d-b}\right)$$

$$= \frac{q}{4\pi\varepsilon_0}\left(\frac{1}{d-b} - \frac{1}{b} - \frac{1}{b} + \frac{1}{d-b}\right) = 2\frac{1}{4\pi\varepsilon_0}q\left(\frac{1}{d-b} - \frac{1}{b}\right) = \boxed{\frac{2q(2b-d)}{4\pi\varepsilon_0 b(d-b)}}$$

33. (*a*) For every element *dq* as labeled in Figure 23-14 on the top half of the ring, there will be a diametrically opposite element of charge *–dq*. The potential due to those two infinitesimal elements will cancel each other, and so the potential due to the entire ring is $\boxed{0}$.

(*b*) We follow Example 21-9 from the textbook. But because the upper and lower halves of the ring are oppositely charged, the parallel components of the fields from diametrically opposite infinitesimal segments of the ring will cancel each other, and the perpendicular components add, in the negative *y* direction. We know then that $\boxed{E_x = 0}$.

$$dE_y = -dE\sin\theta = -\frac{1}{4\pi\varepsilon_0}\frac{dq}{r^2}\sin\theta = -\frac{1}{4\pi\varepsilon_0}\frac{\frac{Q}{2\pi R}d\ell}{\left(x^2+R^2\right)}\frac{R}{\left(x^2+R^2\right)^{1/2}} = -\frac{Q}{8\pi^2\varepsilon_0}\frac{d\ell}{\left(x^2+R^2\right)^{3/2}}$$

$$E_y = \int_0^{2\pi R} dE_y = -\frac{Q}{8\pi^2\varepsilon_0}\frac{1}{\left(x^2+R^2\right)^{3/2}}\int_0^{2\pi R} d\ell = -\frac{Q}{4\pi\varepsilon_0}\frac{R}{\left(x^2+R^2\right)^{3/2}} \;\rightarrow$$

$$\vec{\mathbf{E}} = \boxed{-\frac{Q}{4\pi\varepsilon_0}\frac{R}{\left(x^2+R^2\right)^{3/2}}\hat{\mathbf{j}}}$$

Note that for $x \gg R$, this reduces to $\vec{\mathbf{E}} = -\dfrac{Q}{4\pi\varepsilon_0}\dfrac{R}{x^3}\hat{\mathbf{j}}$, which has the typical distance dependence for the field of a dipole, along the axis of the dipole.

34. The potential at the corner is the sum of the potentials due to each of the charges, using Eq. 23-5.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{(3Q)}{\ell} + \frac{1}{4\pi\varepsilon_0}\frac{Q}{\sqrt{2}\ell} + \frac{1}{4\pi\varepsilon_0}\frac{(-2Q)}{\ell} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{\ell}\left(1+\frac{1}{\sqrt{2}}\right) = \boxed{\frac{1}{4\pi\varepsilon_0}\frac{\sqrt{2}Q}{2\ell}\left(\sqrt{2}+1\right)}$$

35. We follow the development of Example 23-9, with Figure 23-15. The charge on a thin ring of radius R and thickness dR is $dq = \sigma dA = \sigma(2\pi R dR)$. Use Eq. 23-6b to find the potential of a continuous charge distribution.

$$V = \frac{1}{4\pi\varepsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0}\int_{R_1}^{R_2}\frac{\sigma(2\pi R dR)}{\sqrt{x^2+R^2}} = \frac{\sigma}{2\varepsilon_0}\int_{R_1}^{R_2}\frac{R}{\sqrt{x^2+R^2}}dR = \frac{\sigma}{2\varepsilon_0}\left(x^2+R^2\right)^{1/2}\Big|_{R_1}^{R_2}$$

$$= \boxed{\frac{\sigma}{2\varepsilon_0}\left(\sqrt{x^2+R_2^2}-\sqrt{x^2+R_1^2}\right)}$$

36. All of the charge is the same distance from the center of the semicircle – the radius of the semicircle. Use Eq 23-6b to calculate the potential.

$$\ell = \pi r_0 \;\rightarrow\; r_0 = \frac{\ell}{\pi} \;;\; V = \frac{1}{4\pi\varepsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0 r_0}\int dq = \frac{Q}{4\pi\varepsilon_0\frac{\ell}{\pi}} = \boxed{\frac{Q}{4\varepsilon_0\ell}}$$

37. The electric potential energy is the product of the point charge and the electric potential at the location of the charge. Since all points on the ring are equidistant from any point on the axis, the electric potential integral is simple.

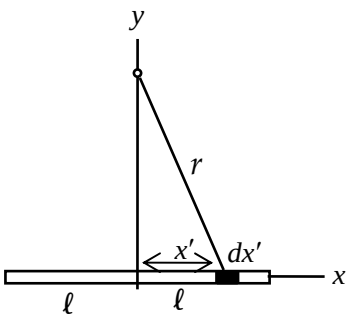
$$U = qV = q\int\frac{dq}{4\pi\varepsilon_0\sqrt{r^2+x^2}} = \frac{q}{4\pi\varepsilon_0\sqrt{r^2+x^2}}\int dq = \frac{qQ}{4\pi\varepsilon_0\sqrt{r^2+x^2}}$$

Energy conservation is used to obtain a relationship between the potential and kinetic energies at the center of the loop and at a point 2.0 m along the axis from the center.

$$K_0 + U_0 = K + U$$

$$0 + \frac{qQ}{4\pi\varepsilon_0\sqrt{r^2}} = \tfrac{1}{2}mv^2 + \frac{qQ}{4\pi\varepsilon_0\sqrt{r^2+x^2}}$$

This is equation is solved to obtain the velocity at x = 2.0 m.

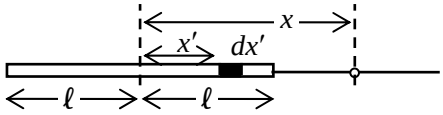


$$v = \sqrt{\frac{qQ}{2\pi\varepsilon_0 m}\left(\frac{1}{r}-\frac{1}{\sqrt{r^2+x^2}}\right)}$$

$$= \sqrt{\frac{(3.0\,\mu\text{C})(15.0\,\mu\text{C})}{2\pi\left(8.85\times10^{-12}\text{C}^2/\text{Nm}^2\right)(7.5\times10^{-3}\text{kg})}\left(\frac{1}{0.12\,\text{m}}-\frac{1}{\sqrt{(0.12\,\text{m})^2+(2.0\,\text{m})^2}}\right)}$$

$$= \boxed{29\text{ m/s}}$$

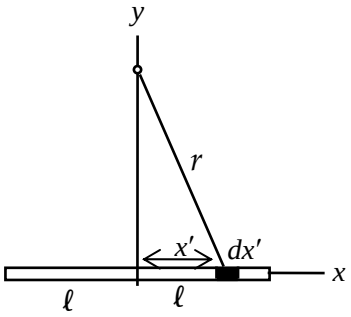
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



38. Use Eq. 23-6b to find the potential of a continuous charge distribution. Choose a differential element of length dx' at position x' along the rod. The charge on the element is $dq = \dfrac{Q}{2\ell}dx'$, and the element is a distance $r = \sqrt{x'^2 + y^2}$ from a point on the *y* axis. Use an indefinite integral from Appendix B-4, page A-7.

$$V_{y\,\text{axis}} = \frac{1}{4\pi\varepsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0}\int_{-\ell}^{\ell}\frac{\frac{Q}{2\ell}dx'}{\sqrt{x'^2+y^2}}$$

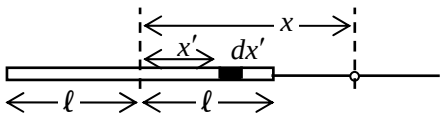
$$= \frac{1}{4\pi\varepsilon_0}\frac{Q}{2\ell}\left[\ln\left(\sqrt{x'^2+y^2}+x'\right)\right]_{-\ell}^{\ell} = \boxed{\frac{Q}{8\pi\varepsilon_0\ell}\left[\ln\left(\frac{\sqrt{\ell^2+y^2}+\ell}{\sqrt{\ell^2+y^2}-\ell}\right)\right]}$$



39. Use Eq. 23-6b to find the potential of a continuous charge distribution. Choose a differential element of length dx' at position x' along the rod. The charge on the element is $dq = \dfrac{Q}{2\ell}dx'$, and the element is a distance $x - x'$ from a point outside the rod on the *x* axis.

$$V = \frac{1}{4\pi\varepsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0}\int_{-\ell}^{\ell}\frac{\frac{Q}{2\ell}dx'}{x-x'} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{2\ell}\left[-\ln\left(x-x'\right)\right]_{-\ell}^{\ell} = \boxed{\frac{Q}{8\pi\varepsilon_0\ell}\left[\ln\left(\frac{x+\ell}{x-\ell}\right)\right]},\ x > \ell$$

40. For both parts of the problem, use Eq. 23-6b to find the potential of a continuous charge distribution. Choose a differential element of length dx' at position x' along the rod. The charge on the element is $dq = \lambda dx' = ax'dx'$.



(*a*) The element is a distance $r = \sqrt{x'^2 + y^2}$ from a point on the *y* axis.

$$V = \frac{1}{4\pi\varepsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0}\int_{-\ell}^{\ell}\frac{ax'dx'}{\sqrt{x'^2+y^2}} = 0$$

The integral is equal to 0 because the region of integration is "even" with respect to the origin, while the integrand is "odd." Alternatively, the antiderivative can be found, and the integral can be shown to be 0. This is to be expected since the potential from points symmetric about the origin would cancel on the *y* axis.

(*b*) The element is a distance $x - x'$ from a point outside the rod on the *x* axis.

$$V = \frac{1}{4\pi\varepsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0}\int_{-\ell}^{\ell}\frac{ax'dx'}{x-x'} = \frac{a}{4\pi\varepsilon_0}\int_{-\ell}^{\ell}\frac{x'dx'}{x-x'}$$

A substitution of $z = x - x'$ can be used to do the integration.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$V = \frac{a}{4\pi\varepsilon_0}\int_{-\ell}^{\ell}\frac{x'dx'}{x-x'} = \frac{a}{4\pi\varepsilon_0}\int_{x+\ell}^{x-\ell}\frac{(x-z)(-dz)}{z} = \frac{a}{4\pi\varepsilon_0}\int_{x-\ell}^{x+\ell}\left(\frac{x}{z}-1\right)dz$$

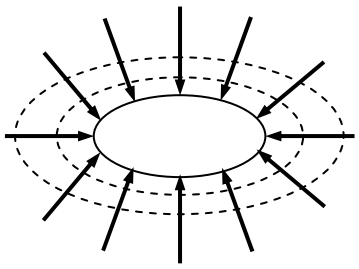
$$= \frac{a}{4\pi\varepsilon_0}\left(x\ln z - z\right)_{x-\ell}^{x+\ell} = \boxed{\frac{a}{4\pi\varepsilon_0}\left[x\ln\left(\frac{x+\ell}{x-\ell}\right)-2\ell\right]},\ x>\ell$$

41. We follow the development of Example 23-9, with Figure 23-15. The charge on a thin ring of radius R and thickness dR will now be $dq = \sigma dA = \left(aR^2\right)\left(2\pi R dR\right)$. Use Eq. 23-6b to find the potential of a continuous charge distribution.

$$V = \frac{1}{4\pi\varepsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0}\int_0^{R_0}\frac{\left(aR^2\right)\left(2\pi R dR\right)}{\sqrt{x^2+R^2}} = \frac{a}{2\varepsilon_0}\int_0^{R_0}\frac{R^3 dR}{\sqrt{x^2+R^2}}$$

A substitution of $x^2+R^2=u^2$ can be used to do the integration.

$$x^2+R^2=u^2 \ \rightarrow\ R^2=u^2-x^2\ ;\ 2RdR=2udu$$



$$V = \frac{a}{2\varepsilon_0}\int_0^{R_0}\frac{R^3dR}{\sqrt{x^2+R^2}} = \frac{a}{2\varepsilon_0}\int_{R=0}^{R=R_0}\frac{\left(u^2-x^2\right)udu}{u} = \frac{a}{2\varepsilon_0}\left[\tfrac{1}{3}u^3-ux^2\right]_{R=0}^{R=R_0}$$

$$= \frac{a}{2\varepsilon_0}\left[\tfrac{1}{3}\left(x^2+R^2\right)^{3/2}-x^2\left(x^2+R^2\right)^{1/2}\right]_{R=0}^{R=R_0}$$

$$= \frac{a}{2\varepsilon_0}\left[\left\{\tfrac{1}{3}\left(x^2+R_0^2\right)^{3/2}-x^2\left(x^2+R_0^2\right)^{1/2}\right\}+\tfrac{2}{3}x^3\right]$$

$$= \boxed{\frac{a}{6\varepsilon_0}\left[\left(R_0^2-2x^2\right)\left(x^2+R_0^2\right)^{1/2}+2x^3\right]},\ x>0$$

42.

43. The electric field from a large plate is uniform with magnitude $E = \sigma/2\varepsilon_0$, with the field pointing away from the plate on both sides. Equation 23-4(a) can be integrated between two arbitrary points to calculate the potential difference between those points.

$$\Delta V = -\int_{x_0}^{x_1}\frac{\sigma}{2\varepsilon_0}dx = \frac{\sigma(x_0-x_1)}{2\varepsilon_0}$$

Setting the change in voltage equal to 100 V and solving for $x_0 - x_1$ gives the distance between field lines.

$$x_0 - x_1 = \frac{2\varepsilon_0\Delta V}{\sigma} = \frac{2\left(8.85\times10^{-12}\ \text{C}^2/\text{Nm}^2\right)(100\ \text{V})}{0.75\times10^{-6}\,\text{C/m}^2} = 2.36\times10^{-3}\,\text{m} \approx \boxed{2\,\text{mm}}$$

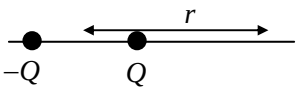
44. The potential at the surface of the sphere is $V_0 = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{r_0}$. The potential outside the sphere is $V = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{r} = V_0\dfrac{r_0}{r}$, and decreases as you move away from the surface. The difference in potential between a given location and the surface is to be a multiple of 100 V.

$$V_0 = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r_0} = \left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(\frac{0.50\times10^{-6}\,\text{C}}{0.44\,\text{m}}\right) = 10,216\,\text{V}$$

$$V_0 - V = V_0 - V_0\frac{r_0}{r} = (100\,\text{V})n \quad\rightarrow\quad r = \frac{V_0}{\left[V_0 - (100\,\text{V})n\right]}r_0$$

(*a*) $r_1 = \dfrac{V_0}{\left[V_0 - (100\,\text{V})1\right]}r_0 = \dfrac{10,216\,\text{V}}{10,116\,\text{V}}(0.44\,\text{m}) = \boxed{0.444\,\text{m}}$

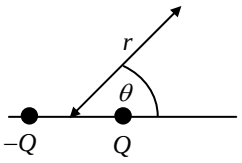
Note that to within the appropriate number of significant figures, this location is at the surface of the sphere. That can be interpreted that we don't know the voltage well enough to be working with a 100-V difference.



(*b*) $r_{10} = \dfrac{V_0}{\left[V_0 - (100\,\text{V})10\right]}r_0 = \dfrac{10,216\,\text{V}}{9,216\,\text{V}}(0.44\,\text{m}) = \boxed{0.49\,\text{m}}$

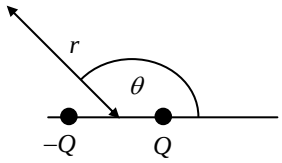
(*c*) $r_{100} = \dfrac{V_0}{\left[V_0 - (100\,\text{V})100\right]}r_0 = \dfrac{10,216\,\text{V}}{216\,\text{V}}(0.44\,\text{m}) = \boxed{21\,\text{m}}$

45. The potential due to the dipole is given by Eq. 23-7.



(*a*) $V = \dfrac{1}{4\pi\varepsilon_0}\dfrac{p\cos\theta}{r^2} = \dfrac{\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(4.8\times10^{-30}\,\text{C}\cdot\text{m}\right)\cos 0}{\left(4.1\times10^{-9}\,\text{m}\right)^2}$

$= \boxed{2.6\times10^{-3}\,\text{V}}$



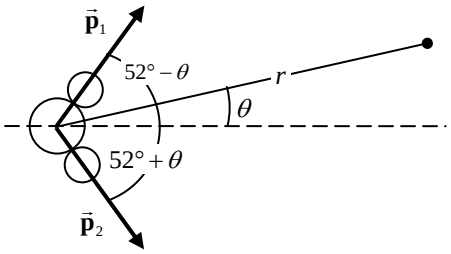
(*b*) $V = \dfrac{1}{4\pi\varepsilon_0}\dfrac{p\cos\theta}{r^2} = \dfrac{\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(4.8\times10^{-30}\,\text{C}\cdot\text{m}\right)\cos 45^\circ}{\left(4.1\times10^{-9}\,\text{m}\right)^2}$

$= \boxed{1.8\times10^{-3}\,\text{V}}$

(*c*) $V = \dfrac{1}{4\pi\varepsilon_0}\dfrac{p\cos\theta}{r^2} = \dfrac{\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(4.8\times10^{-30}\,\text{C}\cdot\text{m}\right)\cos 135^\circ}{\left(1.1\times10^{-9}\,\text{m}\right)^2}$

$= \boxed{-1.8\times10^{-3}\,\text{V}}$

46. (*a*) We assume that $\vec{\mathbf{p}}_1$ and $\vec{\mathbf{p}}_2$ are equal in magnitude, and that each makes a 52° angle with $\vec{\mathbf{p}}$. The magnitude of $\vec{\mathbf{p}}_1$ is also given by $p_1 = qd$, where q is the net charge on the hydrogen atom, and d is the distance between the H and the O.



$$p = 2p_1\cos 52^\circ \quad\rightarrow\quad p_1 = \frac{p}{2\cos 52^\circ} = qd \quad\rightarrow$$

$$q = \frac{p}{2d\cos 52^\circ} = \frac{6.1\times10^{-30}\,\text{C}\cdot\text{m}}{2\left(0.96\times10^{-10}\,\text{m}\right)\cos 52^\circ} = \boxed{5.2\times10^{-20}\,\text{C}}$$

This is about 0.32 times the charge on an electron.

(*b*) Since we are considering the potential far from the dipoles, we will take the potential of each dipole to be given by Eq. 23-7. See the diagram for the angles involved. From part (a), $p_1 = p_2 = \dfrac{p}{2\cos 52°}$.

$$\begin{aligned} V &= V_{p_1} + V_{p_2} \\ &= \frac{1}{4\pi\varepsilon_0}\frac{p_1\cos(52°-\theta)}{r} + \frac{1}{4\pi\varepsilon_0}\frac{p_2\cos(52°+\theta)}{r} \\ &= \frac{1}{4\pi\varepsilon_0 r}\frac{p}{2\cos 52°}\left[\cos(52°-\theta)+\cos(52°+\theta)\right] \\ &= \frac{1}{4\pi\varepsilon_0 r}\frac{p}{2\cos 52°}\left(\cos 52°\cos\theta + \sin 52°\cos\theta + \cos 52°\cos\theta - \sin 52°\cos\theta\right) \\ &= \frac{1}{4\pi\varepsilon_0 r}\frac{p}{2\cos 52°}\left(2\cos 52°\cos\theta\right) = \boxed{\frac{1}{4\pi\varepsilon_0}\frac{p\cos\theta}{r}} \end{aligned}$$

47. $$E = -\frac{dV}{dr} = -\frac{d}{dr}\left(\frac{1}{4\pi\varepsilon_0}\frac{q}{r}\right) = -\frac{q}{4\pi\varepsilon_0}\frac{d}{dr}\left(\frac{1}{r}\right) = -\frac{q}{4\pi\varepsilon_0}\left(-\frac{1}{r^2}\right) = \boxed{\frac{1}{4\pi\varepsilon_0}\frac{q}{r^2}}$$

48. The potential gradient is the negative of the electric field. Outside of a spherically symmetric charge distribution, the field is that of a point charge at the center of the distribution.

$$\frac{dV}{dr} = -E = -\frac{1}{4\pi\varepsilon_0}\frac{q}{r^2} = -\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(92)\left(1.60\times10^{-19}\text{C}\right)}{\left(7.5\times10^{-15}\text{m}\right)^2} = \boxed{-2.4\times10^{21}\ \text{V/m}}$$

49. The electric field between the plates is obtained from the negative derivative of the potential.

$$E = -\frac{dV}{dx} = -\frac{d}{dx}\left[(8.0\ \text{V/m})\,x\ +\ 5.0\ \text{V}\right] = -8.0\ \text{V/m}$$

The charge density on the plates (assumed to be conductors) is then calculated from the electric field between two large plates, $E = \sigma/\varepsilon_0$.

$$\sigma = E\varepsilon_0 = (8.0\,\text{V/m})\left(8.85\times10^{-12}\ \text{C}^2/\text{Nm}^2\right) = \boxed{7.1\times10^{-11}\text{C/m}^2}$$

The plate at the origin has the charge $-7.1\times10^{-11}\text{C/m}^2$ and the other plate, at a positive x, has charge $+7.1\times10^{-11}\text{C/m}^2$ so that the electric field points in the negative direction.

50. We use Eq. 23-9 to find the components of the electric field.

$$E_x = -\frac{\partial V}{\partial x} = 0\ ;\ E_z = -\frac{\partial V}{\partial z} = 0$$

$$E_y = -\frac{\partial V}{\partial y} = -\frac{\partial}{\partial y}\left[\frac{by}{\left(a^2+y^2\right)}\right] = -\frac{\left(a^2+y^2\right)b - by(2y)}{\left(a^2+y^2\right)^2} = \frac{\left(y^2-a^2\right)b}{\left(a^2+y^2\right)^2}$$

$$\vec{\mathbf{E}} = \boxed{\frac{\left(y^2-a^2\right)b}{\left(a^2+y^2\right)^2}\hat{\mathbf{j}}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

51. We use Eq. 23-9 to find the components of the electric field.

$$E_x = -\frac{\partial V}{\partial x} = -2.5y + 3.5yz \;\; ; \;\; E_y = -\frac{\partial V}{\partial y} = -2y - 2.5x + 3.5xz \; ; \; E_z = -\frac{\partial V}{\partial z} = 3.5xy$$

$$\vec{\mathbf{E}} = \boxed{\left(-2.5y + 3.5yz\right)\hat{\mathbf{i}} + \left(-2y - 2.5x + 3.5xz\right)\hat{\mathbf{j}} + \left(3.5xy\right)\hat{\mathbf{k}}}$$

52. We use the potential to find the electric field, the electric field to find the force, and the force to find the acceleration.

$$E_x = -\frac{\partial V}{\partial x} \;\; ; \;\; F_x = qE_x \;\; ; \;\; a_x = \frac{F_x}{m} = \frac{qE_x}{m} = -\frac{q}{m}\frac{\partial V}{\partial x} = -\frac{q}{m}\frac{\partial V}{\partial x}$$

$$a_x\left(x = 2.0\,\text{m}\right) = -\frac{2.0\times10^{-6}\,\text{C}}{5.0\times10^{-5}\,\text{kg}}\left[2\left(2.0\,\text{V/m}^2\right)\left(2.0\,\text{m}\right) - 3\left(3.0\,\text{V/m}^3\right)\left(2.0\,\text{m}\right)^2\right] = \boxed{1.1\,\text{m/s}^2}$$

53. (*a*) The potential along the *y* axis was derived in Problem 38.

$$V_{y\,\text{axis}} = \frac{Q}{8\pi\varepsilon_0\ell}\left[\ln\left(\frac{\sqrt{\ell^2 + y^2} + \ell}{\sqrt{\ell^2 + y^2} - \ell}\right)\right] = \frac{Q}{8\pi\varepsilon_0\ell}\left[\ln\left(\sqrt{\ell^2 + y^2} + \ell\right) - \ln\left(\sqrt{\ell^2 + y^2} - \ell\right)\right]$$

$$E_y = -\frac{\partial V}{\partial y} = -\frac{Q}{8\pi\varepsilon_0\ell}\left[\frac{\frac{1}{2}\left(\ell^2 + y^2\right)^{-1/2}2y}{\sqrt{\ell^2 + y^2} + \ell} - \frac{\frac{1}{2}\left(\ell^2 + y^2\right)^{-1/2}2y}{\sqrt{\ell^2 + y^2} - \ell}\right] = \frac{Q}{4\pi\varepsilon_0 y\sqrt{\ell^2 + y^2}}$$

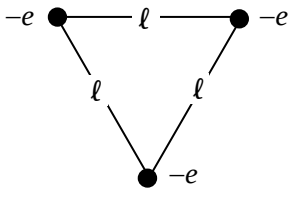
From the symmetry of the problem, this field will point along the *y* axis.

$$\vec{\mathbf{E}} = \boxed{\frac{1}{4\pi\varepsilon_0}\frac{Q}{y\sqrt{\ell^2 + y^2}}\hat{\mathbf{j}}}$$

Note that for $y \gg \ell$, this reduces to the field of a point charge at the origin.

(*b*) The potential along the *x* axis was derived in Problem 39.

$$V_{x\,\text{axis}} = \frac{Q}{8\pi\varepsilon_0\ell}\left[\ln\left(\frac{x + \ell}{x - \ell}\right)\right] = \frac{Q}{8\pi\varepsilon_0\ell}\left[\ln\left(x + \ell\right) - \ln\left(x - \ell\right)\right]$$



$$E_x = -\frac{\partial V}{\partial x} = -\frac{Q}{8\pi\varepsilon_0\ell}\left[\frac{1}{x + \ell} - \frac{1}{x - \ell}\right] = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q}{x^2 - \ell^2}\right)$$

From the symmetry of the problem, this field will point along the *x* axis.

$$\vec{\mathbf{E}} = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q}{x^2 - \ell^2}\right)\hat{\mathbf{i}}$$

Note that for $x \gg \ell$, this reduces to the field of a point charge at the origin.

54. Let the side length of the equilateral triangle be $\boldsymbol{\ell}$. Imagine bringing the electrons in from infinity one at a time. It takes no work to bring the first electron to its final location, because there are no other charges present. Thus $W_1 = 0$. The work done in bringing in the second electron to its final location is equal to the charge on the electron times the potential (due to the first electron) at the final location of the second electron.

Thus $W_2 = \left(-e\right)\left(-\frac{1}{4\pi\varepsilon_0}\frac{e}{\ell}\right) = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{L}$. The work done in bringing the third electron to its final

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

location is equal to the charge on the electron times the potential (due to the first two electrons). Thus $W_3 = (-e)\left(-\frac{1}{4\pi\varepsilon_0}\frac{e}{\ell}-\frac{1}{4\pi\varepsilon_0}\frac{e}{\ell}\right)=\frac{1}{4\pi\varepsilon_0}\frac{2e^2}{\ell}$. The total work done is the sum $W_1+W_2+W_3$.

$$W = W_1+W_2+W_3 = 0+\frac{1}{4\pi\varepsilon_0}\frac{e^2}{\ell}+\frac{1}{4\pi\varepsilon_0}\frac{2e^2}{\ell}=\frac{1}{4\pi\varepsilon_0}\frac{3e^2}{\ell}=\frac{3\left(8.99\times10^9\ \text{N•m}^2/\text{C}^2\right)\left(1.60\times10^{-19}\text{C}\right)^2}{\left(1.0\times10^{-10}\text{m}\right)}$$

$$=\boxed{6.9\times10^{-18}\text{J}}=6.9\times10^{-18}\text{J}\left(\frac{1\text{eV}}{1.60\times10^{-19}\text{J}}\right)=\boxed{43\text{eV}}$$

55. The gain of kinetic energy comes from a loss of potential energy due to conservation of energy, and the magnitude of the potential difference is the energy per unit charge. The helium nucleus has a charge of 2*e*.

$$\Delta V=\frac{\Delta U}{q}=-\frac{\Delta K}{q}=-\frac{125\times10^3\text{eV}}{2e}=\boxed{-62.5\text{kV}}$$

The negative sign indicates that the helium nucleus had to go from a higher potential to a lower potential.

56. The kinetic energy of the particle is given in each case. Use the kinetic energy to find the speed.

(*a*) $\frac{1}{2}mv^2=K \rightarrow v=\sqrt{\frac{2K}{m}}=\sqrt{\frac{2\left(1500\text{eV}\right)\left(1.60\times10^{-19}\text{J/eV}\right)}{9.11\times10^{-31}\text{kg}}}=\boxed{2.3\times10^7\text{ m/s}}$

(*b*) $\frac{1}{2}mv^2=K \rightarrow v=\sqrt{\frac{2K}{m}}=\sqrt{\frac{2\left(1500\text{eV}\right)\left(1.60\times10^{-19}\text{J/eV}\right)}{1.67\times10^{-27}\text{kg}}}=\boxed{5.4\times10^5\text{ m/s}}$

57. The potential energy of the two-charge configuration (assuming they are both point charges) is given by Eq. 23-10.

$$U=\frac{1}{4\pi\varepsilon_0}\frac{Q_1Q_2}{r}=-\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r}$$

$$\Delta U=U_{\text{final}}-U_{\text{initial}}=\frac{e^2}{4\pi\varepsilon_0}\left(\frac{1}{r_{\text{initial}}}-\frac{1}{r_{\text{final}}}\right)$$

$$=\left(8.99\times10^9\ \text{N•m}^2/\text{C}^2\right)\left(1.60\times10^{-19}\text{C}\right)^2\left(\frac{1}{0.110\times10^{-9}\text{m}}-\frac{1}{0.100\times10^{-9}\text{m}}\right)\left(\frac{1\text{eV}}{1.60\times10^{-19}\text{J}}\right)$$

$$=-1.31\text{eV}$$

Thus $\boxed{1.3\text{ eV}}$ of potential energy was lost.

58. The kinetic energy of the alpha particle is given. Use the kinetic energy to find the speed.

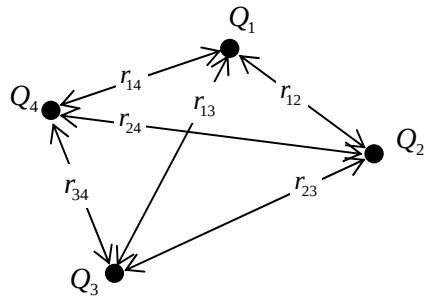
$$\frac{1}{2}mv^2=K \rightarrow v=\sqrt{\frac{2K}{m}}=\sqrt{\frac{2\left(5.53\times10^6\text{eV}\right)\left(1.60\times10^{-19}\text{J/eV}\right)}{6.64\times10^{-27}\text{kg}}}=\boxed{1.63\times10^7\text{ m/s}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

59. Following the same method as presented in Section 23-8, we get the following results.

(*a*) 1 charge: No work is required to move a single charge into a position, so $U_1 = 0$.

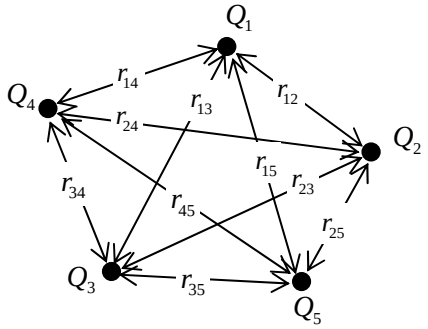
2 charges: This represents the interaction between Q_1 and Q_2.



$$U_2 = \frac{1}{4\pi\varepsilon_0}\frac{Q_1Q_2}{r_{12}}$$

3 charges: This now adds the interactions between $Q_1 \& Q_3$ and $Q_2 \& Q_3$.

$$U_3 = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q_1Q_2}{r_{12}} + \frac{Q_1Q_3}{r_{13}} + \frac{Q_2Q_3}{r_{23}}\right)$$



4 charges: This now adds the interaction between $Q_1 \& Q_4$, $Q_2 \& Q_4$, and $Q_3 \& Q_4$.

$$U_4 = \boxed{\frac{1}{4\pi\varepsilon_0}\left(\frac{Q_1Q_2}{r_{12}} + \frac{Q_1Q_3}{r_{13}} + \frac{Q_1Q_4}{r_{14}} + \frac{Q_2Q_3}{r_{23}} + \frac{Q_2Q_4}{r_{24}} + \frac{Q_3Q_4}{r_{34}}\right)}$$

(*b*) 5 charges: This now adds the interaction between $Q_1 \& Q_5$, $Q_2 \& Q_5$, $Q_3 \& Q_5$, and $Q_4 \& Q_5$.

$$U_5 = \boxed{\frac{1}{4\pi\varepsilon_0}\left(\frac{Q_1Q_2}{r_{12}} + \frac{Q_1Q_3}{r_{13}} + \frac{Q_1Q_4}{r_{14}} + \frac{Q_1Q_5}{r_{15}} + \frac{Q_2Q_3}{r_{23}} + \frac{Q_2Q_4}{r_{24}} + \frac{Q_2Q_5}{r_{25}} + \frac{Q_3Q_4}{r_{34}} + \frac{Q_3Q_5}{r_{35}} + \frac{Q_4Q_5}{r_{45}}\right)}$$

60. (*a*) The potential energy of the four-charge configuration was derived in Problem 59. Number the charges clockwise, starting in the upper right hand corner of the square.

$$U_4 = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q_1Q_2}{r_{12}} + \frac{Q_1Q_3}{r_{13}} + \frac{Q_1Q_4}{r_{14}} + \frac{Q_2Q_3}{r_{23}} + \frac{Q_2Q_4}{r_{24}} + \frac{Q_3Q_4}{r_{34}}\right)$$

$$= \frac{Q^2}{4\pi\varepsilon_0}\left(\frac{1}{b} + \frac{1}{\sqrt{2}b} + \frac{1}{b} + \frac{1}{b} + \frac{1}{\sqrt{2}b} + \frac{1}{b}\right) = \boxed{\frac{Q^2}{4\pi\varepsilon_0 b}\left(4 + \sqrt{2}\right)}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The potential energy of the fifth charge is due to the interaction between the fifth charge and each of the other four charges. Each of those interaction terms is of the same magnitude since the fifth charge is the same distance from each of the other four charges.

$$U_{\substack{5\text{th}\\ \text{charge}}} = \boxed{\frac{Q^2}{4\pi\varepsilon_0 b}\left(4\sqrt{2}\right)}$$

(*c*) If the center charge were moved away from the center, it would be moving closer to 1 or 2 of the other charges. Since the charges are all of the same sign, by moving closer, the center charge would be repelled back towards its original position. Thus it is in a place of stable equilibrium.

(*d*) If the center charge were moved away from the center, it would be moving closer to 1 or 2 of the other charges. Since the corner charges are of the opposite sign as the center charge, the center charge would be attracted towards those closer charges, making the center charge move even farther from the center. So it is in a place of unstable equilibrium.

61. (*a*) The electron was accelerated through a potential difference of 1.33 kV (moving from low potential to high potential) in gaining 1.33 keV of kinetic energy. The proton is accelerated through the opposite potential difference as the electron, and has the exact opposite charge. Thus the proton gains the same kinetic energy, 1.33 keV.

(*b*) Both the proton and the electron have the same KE. Use that to find the ratio of the speeds.

$$\tfrac{1}{2}m_\text{p}v_\text{p}^2 = \tfrac{1}{2}m_\text{e}v_\text{e}^2 \quad\rightarrow\quad \frac{v_\text{e}}{v_\text{p}} = \sqrt{\frac{m_\text{p}}{m_e}} = \sqrt{\frac{1.67\times10^{-27}\,\text{kg}}{9.11\times10^{-31}\,\text{kg}}} = \boxed{42.8}$$

The lighter electron is moving about 43 times faster than the heavier proton.

62. We find the energy by bringing in a small amount of charge at a time, similar to the method given in Section 23-8. Consider the sphere partially charged, with charge $q < Q$. The potential at the surface of the sphere is $V = \dfrac{1}{4\pi\varepsilon_0}\dfrac{q}{r_0}$, and the work to add a charge dq to that sphere will increase the potential energy by $dU = Vdq$. Integrate over the entire charge to find the total potential energy.

$$U = \int dU = \int_0^Q \frac{1}{4\pi\varepsilon_0}\frac{q}{r_0}dq = \boxed{\frac{1}{8\pi\varepsilon_0}\frac{Q^2}{r_0}}$$

63. The two fragments can be treated as point charges for purposes of calculating their potential energy. Use Eq. 23-10 to calculate the potential energy. Using energy conservation, the potential energy is all converted to kinetic energy as the two fragments separate to a large distance.

$$E_\text{initial} = E_\text{final} \quad\rightarrow\quad U_\text{initial} = K_\text{final} = \frac{1}{4\pi\varepsilon_0}\frac{q_1q_2}{r}V$$

$$= \left(8.99\times10^9\ \text{N}\bullet\text{m}^2/\text{C}^2\right)\frac{(38)(54)\left(1.60\times10^{-19}\,\text{C}\right)^2}{\left(5.5\times10^{-15}\,\text{m}\right)+\left(6.2\times10^{-15}\,\text{m}\right)}\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = 250\times10^6\,\text{eV}$$

$$= \boxed{250\,\text{MeV}}$$

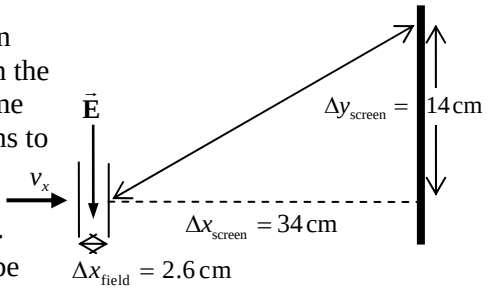
This is about 25% greater than the observed kinetic energy of 200 MeV.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

64. We find the energy by bringing in a small amount of spherically symmetric charge at a time, similar to the method given in Section 23-8. Consider that the sphere has been partially constructed, and so has a charge $q < Q$, contained in a radius $r < r_0$. Since the sphere is made of uniformly charged material, the charge density of the sphere must be $\rho_E = \dfrac{Q}{\frac{4}{3}\pi r_0^3}$. Thus the partially constructed sphere also satisfies $\rho_E = \dfrac{q}{\frac{4}{3}\pi r^3}$, and so $\dfrac{q}{\frac{4}{3}\pi r^3} = \dfrac{Q}{\frac{4}{3}\pi r_0^3} \rightarrow q = \dfrac{Qr^3}{r_0^3}$. The potential at the surface of that sphere can now found.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{q}{r} = \frac{1}{4\pi\varepsilon_0}\frac{\frac{Qr^3}{r_0^3}}{r} = \frac{1}{4\pi\varepsilon_0}\frac{Qr^2}{r_0^3}$$

We now add another infinitesimally thin shell to the partially constructed sphere. The charge of that shell is $dq = \rho_E 4\pi r^2 dr$. The work to add charge dq to the sphere will increase the potential energy by $dU = Vdq$. Integrate over the entire sphere to find the total potential energy.



$$U = \int dU = \int Vdq = \int_0^{r_0} \frac{1}{4\pi\varepsilon_0}\frac{Qr^2}{r_0^3}\rho_E 4\pi r^2 dr = \frac{\rho_E}{\varepsilon_0}\frac{Q}{r_0^3}\int_0^{r_0} r^4 dr = \boxed{\frac{3Q^2}{20\pi\varepsilon_0 r_0}}$$

65. The ideal gas model, from Eq. 18-4, says that $K = \frac{1}{2}mv_{\text{rms}}^2 = \frac{3}{2}kT$.

$$K = \tfrac{1}{2}mv_{\text{rms}}^2 = \tfrac{3}{2}kT \rightarrow v_{\substack{\text{rms}\\273\,\text{K}}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(273\,\text{K}\right)}{9.11\times10^{-31}\,\text{kg}}} = \boxed{1.11\times10^5\,\text{m/s}}$$

$$v_{\substack{\text{rms}\\2700\,\text{K}}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(2700\,\text{K}\right)}{9.11\times10^{-31}\,\text{kg}}} = \boxed{3.5\times10^5\,\text{m/s}}$$

66. If there were no deflecting field, the electrons would hit the center of the screen. If an electric field of a certain direction moves the electrons towards one extreme of the screen, then the opposite field will move the electrons to the opposite extreme of the screen. So we solve for the field to move the electrons to one extreme of the screen. Consider three parts to the electron's motion, and see the diagram, which is a top view. First, during the horizontal acceleration phase, energy will be conserved and so the horizontal speed of the electron v_x can be found from the accelerating potential V. Secondly, during the deflection phase, a vertical force will be applied by the uniform electric field which gives the electron a leftward velocity, v_y. We assume that there is very little leftward displacement during this time. Finally, after the electron leaves the region of electric field, it travels in a straight line to the left edge of the screen.

Acceleration:

$$U_{\text{initial}} = K_{\text{final}} \rightarrow eV = \tfrac{1}{2}mv_x^2 \rightarrow v_x = \sqrt{\frac{2eV}{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Deflection:

time in field: $\Delta x_{\text{field}} = v_x t_{\text{field}} \rightarrow t_{\text{field}} = \dfrac{\Delta x_{\text{field}}}{v_x}$

$$F_y = eE = ma_y \rightarrow a_y = \frac{eE}{m} \qquad v_y = v_0 + a_y t_{\text{field}} = 0 + \frac{eE\Delta x_{\text{field}}}{mv_x}$$

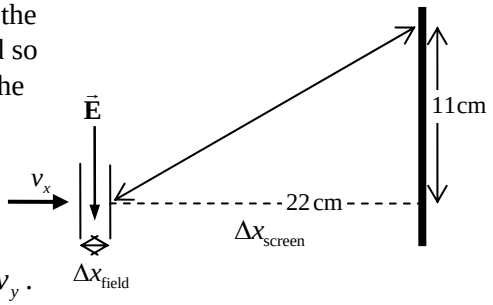
Screen:

$$\Delta x_{\text{screen}} = v_x t_{\text{screen}} \rightarrow t_{\text{screen}} = \frac{\Delta x_{\text{screen}}}{v_x} \qquad \Delta y_{\text{screen}} = v_y t_{\text{screen}} = v_y \frac{\Delta x_{\text{screen}}}{v_x}$$

$$\frac{\Delta y_{\text{screen}}}{\Delta x_{\text{screen}}} = \frac{v_y}{v_x} = \frac{\dfrac{eE\Delta x_{\text{field}}}{mv_x}}{v_x} = \frac{eE\Delta x_{\text{field}}}{mv_x^2} \rightarrow$$

$$E = \frac{\Delta y_{\text{screen}} m v_x^2}{\Delta x_{\text{screen}} e \Delta x_{\text{field}}} = \frac{\Delta y_{\text{screen}} m \dfrac{2eV}{m}}{\Delta x_{\text{screen}} e \Delta x_{\text{field}}} = \frac{2V\Delta y_{\text{screen}}}{\Delta x_{\text{screen}} \Delta x_{\text{field}}} = \frac{2\left(6.0\times10^3\,\text{V}\right)\left(0.14\,\text{m}\right)}{\left(0.34\ \text{m}\right)\left(0.026\,\text{m}\right)}$$

$$= 1.90\times10^5\ \text{V/m} \approx 1.9\times10^5\ \text{V/m}$$



As a check on our assumptions, we calculate the upward distance that the electron would move while in the electric field.

$$\Delta y = v_0 t_{\text{field}} + \tfrac{1}{2} a_y t_{\text{field}}^2 = 0 + \tfrac{1}{2}\left(\frac{eE}{m}\right)\left(\frac{\Delta x_{\text{field}}}{v_x}\right)^2 = \frac{eE\left(\Delta x_{\text{field}}\right)^2}{2m\left(\dfrac{2eV}{m}\right)} = \frac{E\left(\Delta x_{\text{field}}\right)^2}{4V}$$

$$= \frac{\left(1.90\times10^5\ \text{V/m}\right)\left(0.026\,\text{m}\right)^2}{4\left(6000\,\text{V}\right)} = 5.4\times10^{-3}\,\text{m}$$

This is about 4% of the total 15 cm vertical deflection, and so for an estimation, our approximation is acceptable. And so the field must vary from $\boxed{+1.9\times10^5\ \text{V/m to } -1.9\times10^5\ \text{V/m}}$

67. Consider three parts to the electron's motion. First, during the horizontal acceleration phase, energy will be conserved and so the horizontal speed of the electron v_x can be found from the accelerating potential, V. Secondly, during the deflection phase, a vertical force will be applied by the uniform electric field which gives the electron an upward velocity, v_y.

We assume that there is very little upward displacement during this time. Finally, after the electron leaves the region of electric field, it travels in a straight line to the top of the screen.

Acceleration:

$$U_{\text{initial}} = K_{\text{final}} \rightarrow eV = \tfrac{1}{2} m v_x^2 \rightarrow v_x = \sqrt{\frac{2eV}{m}}$$

Deflection:

$$\text{time in field: } \Delta x_{\text{field}} = v_x t_{\text{field}} \quad \rightarrow \quad t_{\text{field}} = \frac{\Delta x_{\text{field}}}{v_x}$$

$$F_y = eE = ma_y \quad \rightarrow \quad a_y = \frac{eE}{m} \qquad v_y = v_0 + a_y t_{\text{field}} = 0 + \frac{eE\Delta x_{\text{field}}}{mv_x}$$

Screen:

$$\Delta x_{\text{screen}} = v_x t_{\text{screen}} \quad \rightarrow \quad t_{\text{screen}} = \frac{\Delta x_{\text{screen}}}{v_x} \qquad \Delta y_{\text{screen}} = v_y t_{\text{screen}} = v_y \frac{\Delta x_{\text{screen}}}{v_x}$$

$$\frac{\Delta y_{\text{screen}}}{\Delta x_{\text{screen}}} = \frac{v_y}{v_x} = \frac{\dfrac{eE\Delta x_{\text{field}}}{mv_x}}{v_x} = \frac{eE\Delta x_{\text{field}}}{mv_x^2} \quad \rightarrow$$

$$E = \frac{\Delta y_{\text{screen}} m v_x^2}{\Delta x_{\text{screen}} e \Delta x_{\text{field}}} = \frac{\Delta y_{\text{screen}} m \dfrac{2eV}{m}}{\Delta x_{\text{screen}} e \Delta x_{\text{field}}} = \frac{2V\Delta y_{\text{screen}}}{\Delta x_{\text{screen}} \Delta x_{\text{field}}} = \frac{2(7200\,\text{V})(0.11\,\text{m})}{(0.22\,\text{m})(0.028\,\text{m})}$$

$$= 2.57\times10^5\ \text{V/m} \approx \boxed{2.6\times10^5\ \text{V/m}}$$

As a check on our assumptions, we calculate the upward distance that the electron would move while in the electric field.

$$\Delta y = v_0 t_{\text{field}} + \tfrac{1}{2} a_y t_{\text{field}}^2 = 0 + \tfrac{1}{2}\left(\frac{eE}{m}\right)\left(\frac{\Delta x_{\text{field}}}{v_x}\right)^2 = \frac{eE(\Delta x_{\text{field}})^2}{2m\left(\dfrac{2eV}{m}\right)} = \frac{E(\Delta x_{\text{field}})^2}{4V}$$

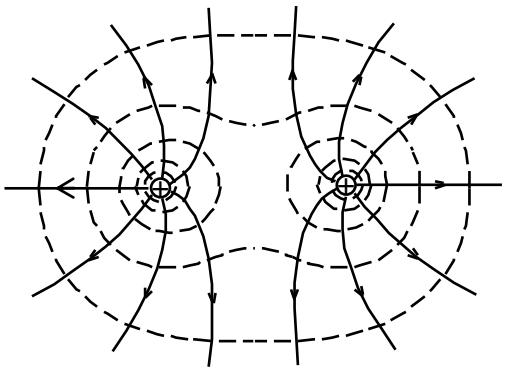
$$= \frac{(2.97\times10^5\ \text{V/m})(0.028\,\text{m})^2}{4(7200\,\text{V})} = 8.1\times10^{-3}\,\text{m}$$

This is about 7% of the total 11 cm vertical deflection, and so for an estimation, our approximation is acceptable.

68. The potential of the earth will increase because the "neutral" Earth will now be charged by the removing of the electrons. The excess charge will be the elementary charge times the number of electrons removed. We approximate this change in potential by using a spherical Earth with all the excess charge at the surface.

$$Q = \left(\frac{1.602\times10^{-19}\,\text{C}}{e^-}\right)\left(\frac{10\ e^-}{\text{H}_2\text{O molecule}}\right)\left(\frac{6.02\times10^{23}\,\text{molecules}}{0.018\,\text{kg}}\right)\left(\frac{1000\,\text{kg}}{\text{m}^3}\right)\tfrac{4}{3}\pi(0.00175\,\text{m})^3$$

$$= 1203\,\text{C}$$



$$V = \frac{1}{4\pi\varepsilon_0}\frac{Q}{R_{\text{Earth}}} = (8.99\times10^9\ \text{N•m}^2/\text{C}^2)\frac{1203\,\text{C}}{6.38\times10^6\,\text{m}} = \boxed{1.7\times10^6\,\text{V}}$$

69. The potential at the surface of a charged sphere is that of a point charge of the same magnitude, located at the center of the sphere.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{q}{r} = (8.99\times10^9\ \text{N•m}^2/\text{C}^2)\frac{(1\times10^{-8}\,\text{C})}{(0.15\,\text{m})} = 599.3\,\text{V} \approx \boxed{600\,\text{V}}$$

70.

71. Let d_1 represent the distance from the left charge to point b, and let d_2 represent the distance from the right charge to point b. Let *Q* represent the positive charges, and let *q* represent the negative charge that moves. The change in potential energy is given by Eq. 23-2b.

$$d_1 = \sqrt{12^2 + 14^2}\,\text{cm} = 18.44\ \text{cm} \qquad d_2 = \sqrt{14^2 + 24^2}\,\text{cm} = 27.78\ \text{cm}$$

$$U_\text{b} - U_\text{a} = q\left(V_\text{b} - V_\text{a}\right) = q\frac{1}{4\pi\varepsilon_0}\left[\left(\frac{Q}{0.1844\,\text{m}} + \frac{Q}{0.2778\,\text{m}}\right) - \left(\frac{Q}{0.12\,\text{m}} + \frac{Q}{0.24\,\text{m}}\right)\right]$$

$$= \frac{1}{4\pi\varepsilon_0}Qq\left[\left(\frac{1}{0.1844\,\text{m}} + \frac{1}{0.2778\,\text{m}}\right) - \left(\frac{1}{0.12\,\text{m}} + \frac{1}{0.24\,\text{m}}\right)\right]$$

$$= \left(8.99\times10^9\ \text{N}\bullet\text{m}^2/\text{C}^2\right)\left(-1.5\times10^{-6}\,\text{C}\right)\left(33\times10^{-6}\,\text{C}\right)\left(-3.477\,\text{m}^{-1}\right) = 1.547\,\text{J} \approx \boxed{1.5\,\text{J}}$$

72. (*a*) All eight charges are the same distance from the center of the cube. Use Eq. 23-5 for the potential of a point charge.

$$V_\text{center} = 8\frac{1}{4\pi\varepsilon_0}\frac{Q}{\frac{\sqrt{3}}{2}\ell} = \boxed{\frac{16}{\sqrt{3}}\frac{1}{4\pi\varepsilon_0}\frac{Q}{\ell}} \approx 9.24\frac{1}{4\pi\varepsilon_0}\frac{Q}{\ell}$$

(*b*) For the seven charges that produce the potential at a corner, three are a distance ℓ away from that corner, three are a distance $\sqrt{2}\ell$ away from that corner, and one is a distance $\sqrt{3}\ell$ away from that corner.

$$V_\text{corner} = 3\frac{1}{4\pi\varepsilon_0}\frac{Q}{\ell} + 3\frac{1}{4\pi\varepsilon_0}\frac{Q}{\sqrt{2}\ell} + \frac{1}{4\pi\varepsilon_0}\frac{Q}{\sqrt{3}\ell} = \boxed{\left(3 + \frac{3}{\sqrt{2}} + \frac{1}{\sqrt{3}}\right)\frac{1}{4\pi\varepsilon_0}\frac{Q}{\ell}} \approx 5.70\frac{1}{4\pi\varepsilon_0}\frac{Q}{\ell}$$

(*c*) The total potential energy of the system is half the energy found by multiplying each charge times the potential at a corner. The factor of half comes from the fact that if you took each charge times the potential at a corner, you would be counting each pair of charges twice.

$$U = \tfrac{1}{2}8\left(QV_\text{corner}\right) = \boxed{4\left(3 + \frac{3}{\sqrt{2}} + \frac{1}{\sqrt{3}}\right)\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{\ell}} \approx 22.8\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{\ell}$$

73. The electric force on the electron must be the same magnitude as the weight of the electron. The magnitude of the electric force is the charge on the electron times the magnitude of the electric field. The electric field is the potential difference per meter: $E = V/d$.

$$F_E = mg \;;\; F_E = |q|E = eV/d \;\rightarrow\; eV/d = mg \;\rightarrow$$

$$V = \frac{mgd}{e} = \frac{\left(9.11\times10^{-31}\,\text{kg}\right)\left(9.80\,\text{m/s}^2\right)\left(0.035\,\text{m}\right)}{1.60\times10^{-19}\,\text{C}} = \boxed{2.0\times10^{-12}\,\text{V}}$$

Since it takes such a tiny voltage to balance gravity, the thousands of volts in a television set are more than enough (by many orders of magnitude) to move electrons upward against the force of gravity.

74. From Problem 59, the potential energy of a configuration of four charges is $U = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q_1Q_2}{r_{12}} + \frac{Q_1Q_3}{r_{13}} + \frac{Q_1Q_4}{r_{14}} + \frac{Q_2Q_3}{r_{23}} + \frac{Q_2Q_4}{r_{24}} + \frac{Q_3Q_4}{r_{34}}\right)$.

Let a side of the square be ℓ, and number the charges clockwise starting with the upper left corner.

$$U = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q_1Q_2}{r_{12}} + \frac{Q_1Q_3}{r_{13}} + \frac{Q_1Q_4}{r_{14}} + \frac{Q_2Q_3}{r_{23}} + \frac{Q_2Q_4}{r_{24}} + \frac{Q_3Q_4}{r_{34}}\right)$$

$$= \frac{1}{4\pi\varepsilon_0}\left(\frac{Q(2Q)}{\ell} + \frac{Q(-3Q)}{\sqrt{2}\ell} + \frac{Q(2Q)}{\ell} + \frac{(2Q)(-3Q)}{\ell} + \frac{(2Q)(2Q)}{\sqrt{2}\ell} + \frac{(-3Q)(2Q)}{\ell}\right)$$

$$= \frac{Q^2}{4\pi\varepsilon_0\ell}\left(\frac{1}{\sqrt{2}} - 8\right) = \left(8.99\times10^9\ \text{N•m}^2/\text{C}^2\right)\frac{\left(3.1\times10^{-6}\,\text{C}\right)^2}{0.080\,\text{m}}\left(\frac{1}{\sqrt{2}} - 8\right) = \boxed{-7.9\,\text{J}}$$

75. The kinetic energy of the electrons (provided by the UV light) is converted completely to potential energy at the plate since they are stopped. Use energy conservation to find the emitted speed, taking the 0 of PE to be at the surface of the barium.

$$\text{KE}_{\text{initial}} = \text{PE}_{\text{final}} \;\rightarrow\; \tfrac{1}{2}mv^2 = qV \;\rightarrow$$

$$v = \sqrt{\frac{2qV}{m}} = \sqrt{\frac{2\left(-1.60\times10^{-19}\,\text{C}\right)\left(-3.02\,\text{V}\right)}{9.11\times10^{-31}\,\text{kg}}} = \boxed{1.03\times10^6\ \text{m/s}}$$

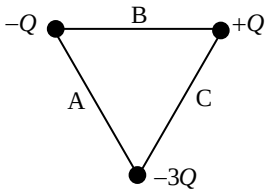
76. To find the angle, the horizontal and vertical components of the velocity are needed. The horizontal component can be found using conservation of energy for the initial acceleration of the electron. That component is not changed as the electron passes through the plates. The vertical component can be found using the vertical acceleration due to the potential difference of the plates, and the time the electron spends between the plates.

Horizontal:

$$\text{PE}_{\text{inital}} = \text{KE}_{\text{final}} \;\rightarrow\; qV = \tfrac{1}{2}mv_x^2 \qquad t = \frac{\Delta x}{v_x}$$

Vertical:

$$F_E = qE_y = ma = m\frac{\left(v_y - v_{y0}\right)}{t} \;\rightarrow\; v_y = \frac{qE_yt}{m} = \frac{qE_y\Delta x}{mv_x}$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Combined:

$$\tan\theta = \frac{v_y}{v_x} = \frac{\dfrac{qE_y\Delta x}{mv_x}}{v_x} = \frac{qE_y\Delta x}{mv_x^2} = \frac{qE_y\Delta x}{2qV} = \frac{E_y\Delta x}{2V} = \frac{\left(\dfrac{250\,\text{V}}{0.013\,\text{m}}\right)(0.065\,\text{m})}{2(5500\,\text{V})} = 0.1136$$

$$\theta = \tan^{-1} 0.1136 = \boxed{6.5^\circ}$$

77. Use Eq. 23-5 to find the potential due to each charge. Since the triangle is equilateral, the 30-60-90 triangle relationship says that the distance from a corner to the midpoint of the opposite side is $\sqrt{3}\ell/2$.

$$V_A = \frac{1}{4\pi\varepsilon_0}\frac{(-Q)}{\ell/2} + \frac{1}{4\pi\varepsilon_0}\frac{(-3Q)}{\ell/2} + \frac{1}{4\pi\varepsilon_0}\frac{(Q)}{\sqrt{3}\ell/2} = \frac{1}{4\pi\varepsilon_0}\frac{2Q}{\ell}\left(-4+\frac{1}{\sqrt{3}}\right)$$

$$= \boxed{\frac{Q}{\pi\varepsilon_0\ell}\left(\frac{\sqrt{3}}{6}-2\right)}$$

$$V_B = \frac{1}{4\pi\varepsilon_0}\frac{(-Q)}{\ell/2} + \frac{1}{4\pi\varepsilon_0}\frac{(Q)}{\ell/2} + \frac{1}{4\pi\varepsilon_0}\frac{(-3Q)}{\sqrt{3}\ell/2} = -\frac{1}{4\pi\varepsilon_0}\frac{6Q}{\sqrt{3}\ell} = \boxed{-\frac{\sqrt{3}Q}{2\pi\varepsilon_0\ell}}$$

$$V_C = \frac{1}{4\pi\varepsilon_0}\frac{(Q)}{\ell/2} + \frac{1}{4\pi\varepsilon_0}\frac{(-3Q)}{\ell/2} + \frac{1}{4\pi\varepsilon_0}\frac{(-Q)}{\sqrt{3}\ell/2} = -\frac{1}{4\pi\varepsilon_0}\frac{2Q}{\ell}\left(2+\frac{1}{\sqrt{3}}\right) = \boxed{-\frac{Q}{\pi\varepsilon_0\ell}\left(1+\frac{\sqrt{3}}{6}\right)}$$

78. Since the E-field points downward, the surface of the Earth is a lower potential than points above the surface. Call the surface of the Earth 0 volts. Then a height of 2.00 m has a potential of 300 V. We also call the surface of the Earth the 0 location for gravitational PE. Write conservation of energy relating the charged spheres at 2.00 m (where their speed is 0) and at ground level (where their electrical and gravitational potential energies are 0).

$$E_{\text{initial}} = E_{\text{final}} \quad\rightarrow\quad mgh + qV = \tfrac{1}{2}mv^2 \quad\rightarrow\quad v = \sqrt{2\left(gh + \frac{qV}{m}\right)}$$

$$v_+ = \sqrt{2\left[\left(9.80\,\text{m/s}^2\right)(2.00\,\text{m}) + \frac{\left(4.5\times10^{-4}\,\text{C}\right)(300\,\text{V})}{(0.340\,\text{kg})}\right]} = 6.3241\,\text{m/s}$$

$$v_- = \sqrt{2\left[\left(9.80\,\text{m/s}^2\right)(2.00\,\text{m}) + \frac{\left(-4.5\times10^{-4}\,\text{C}\right)(300\,\text{V})}{(0.340\,\text{kg})}\right]} = 6.1972\,\text{m/s}$$

$$v_+ - v_- = 6.3241\,\text{m/s} - 6.1972\,\text{m/s} = \boxed{0.13\,\text{m/s}}$$

79. (*a*) The energy is related to the charge and the potential difference by Eq. 23-3.

$$\Delta U = q\Delta V \quad\rightarrow\quad \Delta V = \frac{\Delta U}{q} = \frac{4.8\times10^6\,\text{J}}{4.0\,\text{C}} = \boxed{1.2\times10^6\,\text{V}}$$

(*b*) The energy (as heat energy) is used to raise the temperature of the water and boil it. Assume that room temperature is 20°C.

$$Q = mc\Delta T + mL_f \quad\rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$m = \frac{Q}{c\Delta T + L_{\text{f}}} = \frac{4.8\times10^{6}\,\text{J}}{\left(4186\dfrac{\text{J}}{\text{kg}\bullet\text{C}^\circ}\right)(80\,\text{C}^\circ)+\left(22.6\times10^{5}\dfrac{\text{J}}{\text{kg}}\right)} = \boxed{1.8\,\text{kg}}$$

80. Use Eq. 23-7 for the dipole potential, and use Eq. 23-9 to determine the electric field.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{p\cos\theta}{r^2} = \frac{p}{4\pi\varepsilon_0}\frac{x}{\left(x^2+y^2\right)^{1/2}} = \frac{p}{4\pi\varepsilon_0}\frac{x}{\left(x^2+y^2\right)^{3/2}}$$

$$E_x = -\frac{\partial V}{\partial x} = -\frac{p}{4\pi\varepsilon_0}\left[\frac{\left(x^2+y^2\right)^{3/2} - x\,\frac{3}{2}\left(x^2+y^2\right)^{1/2}2x}{\left(x^2+y^2\right)^3}\right] = \boxed{\frac{p}{4\pi\varepsilon_0}\left[\frac{2x^2-y^2}{\left(x^2+y^2\right)^{5/2}}\right]}$$

$$= \frac{p}{4\pi\varepsilon_0}\left[\frac{2\cos^2\theta-\sin^2\theta}{r^3}\right]$$

$$E_y = -\frac{\partial V}{\partial y} = -\frac{px}{4\pi\varepsilon_0}\left[-\tfrac{3}{2}\left(x^2+y^2\right)^{-5/2}2y\right] = \boxed{\frac{p}{4\pi\varepsilon_0}\left[\frac{3xy}{\left(x^2+y^2\right)^{5/2}}\right]}\frac{p}{4\pi\varepsilon_0}\left[\frac{3\cos\theta\sin\theta}{r^3}\right]$$

Notice the $\dfrac{1}{r^3}$ dependence in both components, which is indicative of a dipole field.

81. (*a*) Since the reference level is given as $V = 0$ at $r = \infty$, the potential outside the shell is that of a point charge with the same total charge.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r} = \frac{1}{4\pi\varepsilon_0}\frac{\rho_{\text{E}}\left(\frac{4}{3}\pi r_2^3 - \frac{4}{3}\pi r_1^3\right)}{r} = \boxed{\frac{\rho_{\text{E}}}{3\varepsilon_0}\frac{\left(r_2^3-r_1^3\right)}{r}},\ r > r_2$$

Note that the potential at the surface of the shell is $V_{r_2} = \dfrac{\rho_{\text{E}}}{3\varepsilon_0}\left(r_2^2 - \dfrac{r_1^3}{r_2}\right)$.

(*b*) To find the potential in the region $r_1 < r < r_2$, we need the electric field in that region. Since the charge distribution is spherically symmetric, Gauss's law may be used to find the electric field.

$$\oint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = E\left(4\pi r^2\right) = \frac{Q_{\text{encl}}}{\varepsilon_0} \quad\rightarrow\quad E = \frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{encl}}}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{\rho_{\text{E}}\left(\frac{4}{3}\pi r^3 - \frac{4}{3}\pi r_1^3\right)}{r^2} = \frac{\rho_{\text{E}}}{3\varepsilon_0}\frac{\left(r^3-r_1^3\right)}{r^2}$$

The potential in that region is found from Eq. 23-4a. The electric field is radial, so we integrate along a radial line so that $\vec{\mathbf{E}}\bullet d\vec{\boldsymbol{\ell}} = E dr$.

$$V_r - V_{r_2} = -\int_{r_2}^{r}\vec{\mathbf{E}}\bullet d\vec{\boldsymbol{\ell}} = -\int_{r_2}^{r} E\,dr = -\int_{r_2}^{r}\frac{\rho_{\text{E}}}{3\varepsilon_0}\frac{\left(r^3-r_1^3\right)}{r^2}dr = -\frac{\rho_{\text{E}}}{3\varepsilon_0}\int_{r_2}^{r}\left(r - \frac{r_1^3}{r^2}\right)dr = -\frac{\rho_{\text{E}}}{3\varepsilon_0}\left(\tfrac{1}{2}r^2 + \frac{r_1^3}{r}\right)_{r_2}^{r}$$

$$V_r = V_{r_2} + \left[-\frac{\rho_{\text{E}}}{3\varepsilon_0}\left(\tfrac{1}{2}r^2 + \frac{r_1^3}{r}\right)_{r_2}^{r}\right] = \frac{\rho_{\text{E}}}{3\varepsilon_0}\left(\tfrac{3}{2}r_2^2 - \tfrac{1}{2}r^2 - \frac{r_1^3}{r}\right) = \boxed{\frac{\rho_{\text{E}}}{\varepsilon_0}\left(\tfrac{1}{2}r_2^2 - \tfrac{1}{6}r^2 - \tfrac{1}{3}\frac{r_1^3}{r}\right)},\ r_1 < r < r_2$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) Inside the cavity there is no electric field, so the potential is constant and has the value that it has on the cavity boundary.

$$V_{r_1} = \frac{\rho_E}{\varepsilon_0}\left(\tfrac{1}{2}r_2^2 - \tfrac{1}{6}r_1^2 - \tfrac{1}{3}\frac{r_1^3}{r_1}\right) = \boxed{\frac{\rho_E}{2\varepsilon_0}\left(r_2^2 - r_1^2\right)},\ r < r_1$$

The potential is continuous at both boundaries.

82. We follow the development of Example 23-9, with Figure 23-15. The charge density of the ring is $\sigma = \left(\dfrac{Q}{\pi R_0^2 - \pi\left(\frac{1}{2}R_0\right)^2}\right) = \dfrac{4Q}{3\pi R_0^2}$. The charge on a thin ring of radius *R* and thickness *dR* is $dq = \sigma dA = \dfrac{4Q}{3\pi R_0^2}\left(2\pi R dR\right)$. Use Eq. 23-6b to find the potential of a continuous charge distribution.

$$V = \frac{1}{4\pi\varepsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\varepsilon_0}\int_{\frac{1}{2}R_0}^{R_0}\frac{\frac{4Q}{3\pi R_0^2}\left(2\pi R dR\right)}{\sqrt{x^2+R^2}} = \frac{2Q}{3\varepsilon_0\pi R_0^2}\int_{\frac{1}{2}R_0}^{R_0}\frac{R}{\sqrt{x^2+R^2}}dR = \frac{2Q}{3\varepsilon_0\pi R_0^2}\left(x^2+R^2\right)^{1/2}\Big|_{\frac{1}{2}R_0}^{R_0}$$

$$= \frac{2Q}{3\varepsilon_0\pi R_0^2}\left(\sqrt{x^2+R_0^2} - \sqrt{x^2+\tfrac{1}{4}R_0^2}\right)$$

83. From Example 22-6, the electric field due to a long wire is radial relative to the wire, and is of magnitude $E = \dfrac{1}{2\pi\varepsilon_0}\dfrac{\lambda}{R}$. If the charge density is positive, the field lines point radially away from the wire. Use Eq. 23-41 to find the potential difference, integrating along a line that is radially outward from the wire.

$$V_a - V_b = -\int_{R_b}^{R_a}\vec{\mathbf{E}}\bullet\left(d\vec{\boldsymbol{\ell}}\right) = -\int_{R_b}^{R_a}\frac{1}{2\pi\varepsilon_0}\frac{\lambda}{R}dR = -\frac{\lambda}{2\pi\varepsilon_0}\ln\left(R_a - R_b\right) = \boxed{\frac{\lambda}{2\pi\varepsilon_0}\ln\frac{R_b}{R_a}}$$

84. (*a*) We may treat the sphere as a point charge located at the center of the field. Then the electric field at the surface is $E_{\text{surface}} = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{r_0^2}$, and the potential at the surface is $V_{\text{surface}} = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{r_0}$.

$$V_{\text{surface}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r_0} = E_{\text{surface}}r_0 = E_{\text{breakdown}}r_0 = \left(3\times10^6\ \text{V/m}\right)\left(0.20\ \text{m}\right) = \boxed{6\times10^5\ \text{V}}$$

(*b*) $V_{\text{surface}} = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{r_0} \rightarrow Q = \left(4\pi\varepsilon_0\right)r_0V_{\text{surface}} = \dfrac{\left(0.20\ \text{m}\right)\left(6\times10^5\ \text{V}\right)}{\left(8.99\times10^9\ \text{N}\bullet\text{m}^2/\text{C}^2\right)} = 1.33\times10^{-5}\ \text{C} \approx \boxed{1\times10^{-5}\ \text{C}}$

85. (*a*) The voltage at $x = 0.20$ m is obtained by inserting the given data directly into the voltage equation.

$$V\left(0.20\ \text{m}\right) = \frac{B}{\left(x^2+R^2\right)^2} = \frac{150\ \text{V}\bullet\text{m}^4}{\left[\left(0.20\ \text{m}\right)^2 + \left(0.20\ \text{m}\right)^2\right]^2} = \boxed{23\ \text{kV}}$$

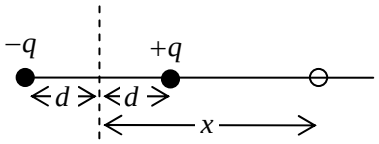
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The electric field is the negative derivative of the potential.

$$\vec{\mathbf{E}}(x) = -\frac{d}{dx}\left[\frac{B}{\left(x^2+R^2\right)^2}\right]\hat{\mathbf{i}} = \boxed{\frac{4Bx\hat{\mathbf{i}}}{\left(x^2+R^2\right)^3}}$$

Since the voltage only depends on x the electric field points in the positive x direction.

(*c*) Inserting the given values in the equation of part (*b*) gives the electric field at $x = 0.20$ m



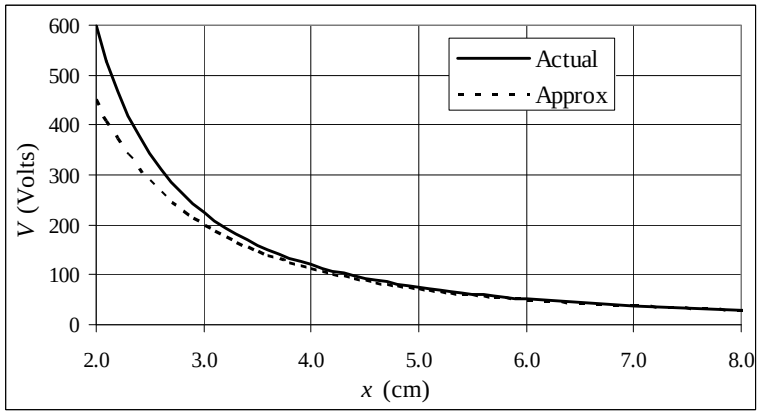
$$\vec{\mathbf{E}}(0.20\text{ m}) = \frac{4\left(150\text{ V}\cdot\text{m}^4\right)(0.20\text{ m})\hat{\mathbf{i}}}{\left[(0.20\text{ m})^2+(0.20\text{ m})^2\right]^3} = \boxed{2.3\times10^5\text{ V/m}\,\hat{\mathbf{i}}}$$

86. Use energy conservation, equating the energy of charge $-q_1$ at its initial position to its final position at infinity. Take the speed at infinity to be 0, and take the potential of the point charges to be 0 at infinity.

$$E_{\text{initial}} = E_{\text{final}} \;\rightarrow\; K_{\text{initial}} + U_{\text{initial}} = K_{\text{final}} + U_{\text{final}} \;\rightarrow\; \tfrac{1}{2}mv_0^2 + (-q_1)V_{\substack{\text{initial}\\\text{point}}} = \tfrac{1}{2}mv_{\text{final}}^2 + (-q_1)V_{\substack{\text{final}\\\text{point}}}$$

$$\tfrac{1}{2}mv_0^2 + (-q_1)\frac{1}{4\pi\varepsilon_0}\frac{2q_2}{\sqrt{a^2+b^2}} = 0+0 \;\rightarrow\; v_0 = \boxed{\sqrt{\frac{1}{m\pi\varepsilon_0}\frac{q_1q_2}{\sqrt{a^2+b^2}}}}$$

87. (*a*) From the diagram, the potential at x is the potential of two point charges.



$$V_{\text{exact}} = \frac{1}{4\pi\varepsilon_0}\left(\frac{q}{x-d}\right)+\frac{1}{4\pi\varepsilon_0}\left(\frac{-q}{x+d}\right)$$

$$= \frac{1}{4\pi\varepsilon_0}\left[\frac{2qd}{\left(x^2-d^2\right)}\right],\quad q = 1.0\times10^{-9}\text{ C},\ d = 0.010\text{ m}$$

(*b*) The approximate potential is given by Eq. 23-7, with $\theta = 0$, $p = 2qd$, and $r = x$.

$$V_{\text{approx}} = \frac{1}{4\pi\varepsilon_0}\frac{2qd}{x^2}$$

To make the difference at small distances more apparent, we have plotted from 2.0 cm to 8.0 cm. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH23.XLS," on tab "Problem 23.87."

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

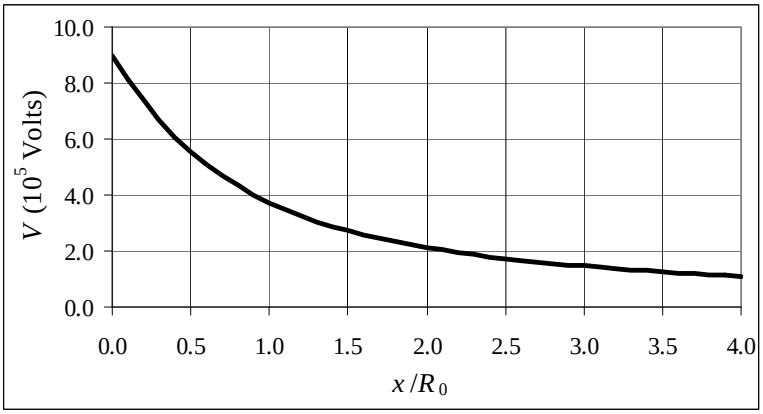
88. The electric field can be determined from the potential by using Eq. 23-8, differentiating with respect to x.

$$E(x) = -\frac{dV(x)}{dx} = -\frac{d}{dx}\left[\frac{Q}{2\pi\varepsilon_0 R_0^2}\left[\left(x^2+R_0^2\right)^{1/2} - x\right]\right] = -\frac{Q}{2\pi\varepsilon_0 R_0^2}\left[\tfrac{1}{2}\left(x^2+R_0^2\right)^{-1/2}(2x) - 1\right]$$

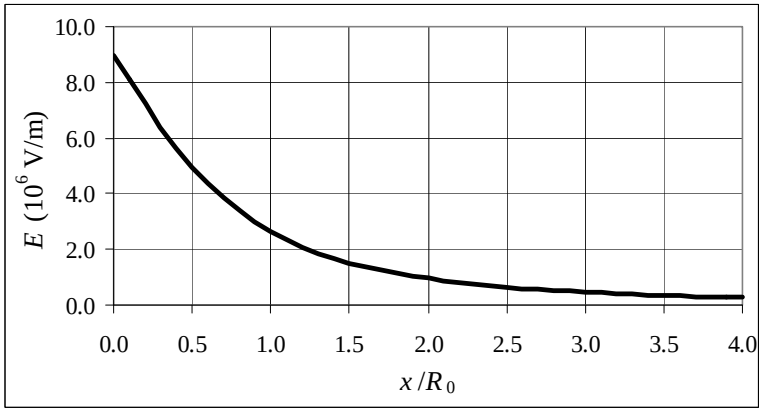
$$= \boxed{\frac{Q}{2\pi\varepsilon_0 R_0^2}\left[1 - \frac{x}{\left(x^2+R_0^2\right)^{1/2}}\right]}$$

Express V and E in terms of x/R_0. Let $X = x/R_0$.

$$V(x) = \frac{Q}{2\pi\varepsilon_0 R_0^2}\left[\left(x^2+R_0^2\right)^{1/2} - x\right] = \frac{2Q}{4\pi\varepsilon_0 R_0}\left(\sqrt{X^2+1} - X\right)$$



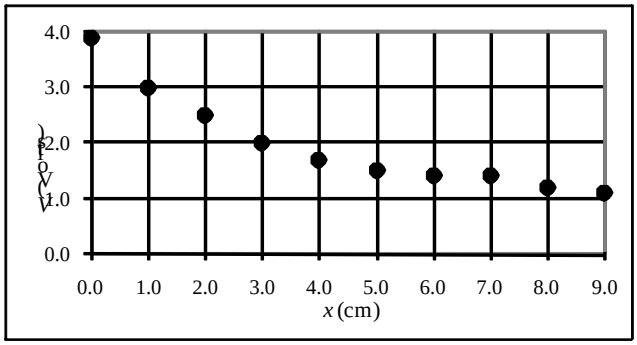
$$= \left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{2\left(5.0\times10^{-6}\,\text{C}\right)}{0.10\,\text{m}}\left(\sqrt{X^2+1} - X\right) = \left(8.99\times10^5\,\text{V}\right)\left(\sqrt{X^2+1} - X\right)$$



$$E(x) = \frac{Q}{2\pi\varepsilon_0 R_0^2}\left[1 - \frac{x}{\left(x^2+R_0^2\right)^{1/2}}\right] = \frac{2Q}{4\pi\varepsilon_0 R_0^2}\left[1 - \frac{X}{\sqrt{X^2+1}}\right]$$

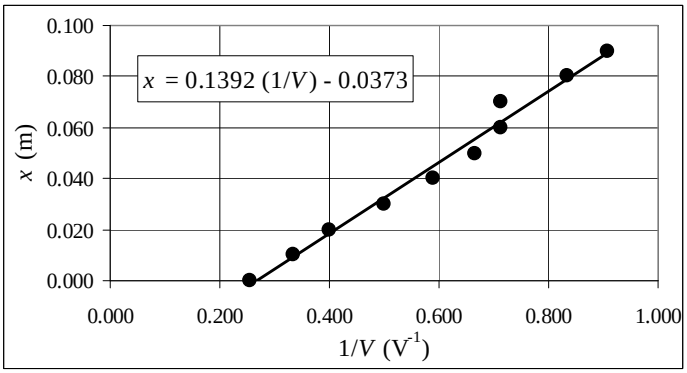
$$= \left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{2\left(5.0\times10^{-6}\,\text{C}\right)}{\left(0.10\,\text{m}\right)^2}\left[1 - \frac{X}{\sqrt{X^2+1}}\right]$$

$$= \left(8.99\times10^6\ \text{V/m}\right)\left[1 - \frac{X}{\sqrt{X^2+1}}\right]$$



The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH23.XLS," on tab "Problem 23.88."

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



89. (*a*) If the field is caused by a point charge, the potential will have a graph that has the appearance of $1/r$ behavior, which means that the potential change per unit of distance will decrease as potential is measured farther from the charge. If the field is caused by a sheet of charge, the potential will have a linear decrease with distance. The graph indicates that the field is caused by a point charge. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH23.XLS," on tab "Problem 23.89a."

(*b*) Assuming the field is caused by a point charge, we assume the charge is at $x = d$, and then the potential is given by $V = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{x-d}$. This can be rearranged to the following.

$$V = \frac{1}{4\pi\varepsilon_0}\frac{Q}{x-d} \quad \rightarrow$$

$$x = \frac{1}{V}\frac{Q}{4\pi\varepsilon_0} + d$$

If we plot x vs. $\dfrac{1}{V}$, the slope is $\dfrac{Q}{4\pi\varepsilon_0}$, which can be used to determine the charge.

$$\text{slope} = 0.1392\ \text{m}\bullet\text{V} = \frac{Q}{4\pi\varepsilon_0} \quad \rightarrow$$

$$Q = 4\pi\varepsilon_0\left(0.1392\ \text{m}\bullet\text{V}\right) = \frac{\left(0.1392\ \text{m}\bullet\text{V}\right)}{\left(8.99\times10^{9}\ \text{N}\bullet\text{m}^2/\text{C}^2\right)} = \boxed{1.5\times10^{-11}\,\text{C}}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH23.XLS," on tab "Problem 23.89b."

(*c*) From the above equation, the *y* intercept of the graph is the location of the charge, *d*. So the charge is located at $x = d = -0.0373\,\text{m} \approx \boxed{3.7\,\text{cm from the first measured position}}$.

CHAPTER 24: Capacitance, Dielectrics, Electric Energy Storage

Responses to Questions

1. Yes. If the conductors have different shapes, then even if they have the same charge, they will have different charge densities and therefore different electric fields near the surface. There can be a potential difference between them. The definition of capacitance $C = Q/V$ cannot be used here because it is defined for the case where the charges on the two conductors of the capacitor are equal and opposite.

2. Underestimate. If the separation between the plates is not very small compared to the plate size, then fringing cannot be ignored and the electric field (for a given charge) will actually be smaller. The capacitance is inversely proportional to potential and, for parallel plates, also inversely proportional to the field, so the capacitance will actually be larger than that given by the formula.

3. Ignoring fringing field effects, the capacitance would decrease by a factor of 2, since the area of overlap decreases by a factor of 2. (Fringing effects might actually be noticeable in this configuration.)

4. When a capacitor is first connected to a battery, charge flows to one plate. Because the plates are separated by an insulating material, charge cannot cross the gap. An equal amount of charge is therefore repelled from the opposite plate, leaving it with a charge that is equal and opposite to the charge on the first plate. The two conductors of a capacitor will have equal and opposite charges even if they have different sizes or shapes.

5. Charge a parallel-plate capacitor using a battery with a known voltage V. Let the capacitor discharge through a resistor with a known resistance R and measure the time constant. This will allow calculation of the capacitance C. Then use $C = \varepsilon_0 A/d$ and solve for ε_0.

6. Parallel. The equivalent capacitance of the three capacitors in parallel will be greater than that of the same three capacitors in series, and therefore they will store more energy when connected to a given potential difference if they are in parallel.

7. If a large copper sheet of thickness ℓ is inserted between the plates of a parallel-plate capacitor, the charge on the capacitor will appear on the large flat surfaces of the copper sheet, with the negative side of the copper facing the positive side of the capacitor. This arrangement can be considered to be two capacitors in series, each with a thickness of $\frac{1}{2}(d-\ell)$. The new net capacitance will be $C' = \varepsilon_0 A/(d-\ell)$, so the capacitance of the capacitor will be reduced.

8. A force is required to increase the separation of the plates of an isolated capacitor because you are pulling a positive plate away from a negative plate. The work done in increasing the separation goes into increasing the electric potential energy stored between the plates. The capacitance decreases, and the potential between the plates increases since the charge has to remain the same.

9. (*a*) The energy stored quadruples since the potential difference across the plates doubles and the capacitance doesn't change: $U = \frac{1}{2}CV^2$.

   (*b*) The energy stored quadruples since the charge doubles and the capacitance doesn't change: $U = \frac{1}{2}\frac{Q^2}{C}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) If the separation between the plates doubles, the capacitance is halved. The potential difference across the plates doesn't change if the capacitor remains connected to the battery, so the energy stored is also halved: $U = \frac{1}{2}CV^2$.

10. (*c*) If the voltage across a capacitor is doubled, the amount of energy it can store is quadrupled: $U = \frac{1}{2}CV^2$.

11. The dielectric will be pulled into the capacitor by the electrostatic attractive forces between the charges on the capacitor plates and the polarized charges on the dielectric's surface. (Note that the addition of the dielectric decreases the energy of the system.)

12. If the battery remains connected to the capacitor, the energy stored in the electric field of the capacitor will increase as the dielectric is inserted. Since the energy of the system increases, work must be done and the dielectric will have to be pushed into the area between the plates. If it is released, it will be ejected.

13. (*a*) If the capacitor is isolated, *Q* remains constant, and $U = \frac{1}{2}\frac{Q^2}{C}$ becomes $U' = \frac{1}{2}\frac{Q^2}{KC}$ and the stored energy decreases.

(*b*) If the capacitor remains connected to a battery so *V* does not change, $U = \frac{1}{2}CV^2$ becomes $U' = \frac{1}{2}KCV^2$, and the stored energy increases.

14. For dielectrics consisting of polar molecules, one would expect the dielectric constant to decrease with temperature. As the thermal energy increases, the molecular vibrations will increase in amplitude, and the polar molecules will be less likely to line up with the electric field.

15. When the dielectric is removed, the capacitance decreases. The potential difference across the plates remains the same because the capacitor is still connected to the battery. If the potential difference remains the same and the capacitance decreases, the charge on the plates and the energy stored in the capacitor must also decrease. (Charges return to the battery.) The electric field between the plates will stay the same because the potential difference across the plates and the distance between the plates remain constant.

16. For a given configuration of conductors and dielectrics, *C* is the proportionality constant between the voltage between the plates and the charge on the plates.

17. The dielectric constant is the ratio of the capacitance of a capacitor with the dielectric between the plates to the capacitance without the dielectric. If a conductor were inserted between the plates of a capacitor such that it filled the gap and touched both plates, the capacitance would drop to zero since charge would flow from one plate to the other. So, the dielectric constant of a good conductor would be zero.

Solutions to Problems

1. The capacitance is found from Eq. 24-1.

$$Q = CV \quad \rightarrow \quad C = \frac{Q}{V} = \frac{2.8\times10^{-3}\,\text{C}}{930\,\text{V}} = 3.0\times10^{-6}\,\text{F} = \boxed{3.0\,\mu\text{F}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2. We assume the capacitor is fully charged, according to Eq. 24-1.

$$Q = CV = \left(12.6\times10^{-6}\,\text{F}\right)\left(12.0\,\text{V}\right) = \boxed{1.51\times10^{-4}\,\text{C}}$$

3. The capacitance is found from Eq. 24-1.

$$Q = CV \;\rightarrow\; C = \frac{Q}{V} = \frac{75\times10^{-12}\,\text{C}}{24.0\,\text{V}} = 3.1\times10^{-12}\,\text{F} = \boxed{3.1\,\text{pF}}$$

4. Let Q_1 and V_1 be the initial charge and voltage on the capacitor, and let Q_2 and V_2 be the final charge and voltage on the capacitor. Use Eq. 24-1 to relate the charges and voltages to the capacitance.

$$Q_1 = CV_1 \quad Q_2 = CV_2 \quad Q_2 - Q_1 = CV_2 - CV_1 = C\left(V_2 - V_1\right) \;\rightarrow$$

$$C = \frac{Q_2 - Q_1}{V_2 - V_1} = \frac{26\times10^{-6}\,\text{C}}{50\,\text{V}} = 5.2\times10^{-7}\,\text{F} = \boxed{0.52\,\mu\text{F}}$$

5. After the first capacitor is disconnected from the battery, the total charge must remain constant. The voltage across each capacitor must be the same when they are connected together, since each capacitor plate is connected to a corresponding plate on the other capacitor by a constant-potential connecting wire. Use the total charge and the final potential difference to find the value of the second capacitor.

$$Q_{\text{Total}} = C_1 V_{1\,\text{initial}} \qquad Q_{1\,\text{final}} = C_1 V_{\text{final}} \qquad Q_{2\,\text{final}} = C_2 V_{\text{final}}$$

$$Q_{\text{Total}} = Q_{1\,\text{final}} + Q_{2\,\text{final}} = \left(C_1 + C_2\right)V_{\text{final}} \;\rightarrow\; C_1 V_{1\,\text{initial}} = \left(C_1 + C_2\right)V_{\text{final}} \;\rightarrow$$

$$C_2 = C_1\left(\frac{V_{1\,\text{initial}}}{V_{\text{final}}} - 1\right) = \left(7.7\times10^{-6}\,\text{F}\right)\left(\frac{125\,\text{V}}{15\,\text{V}} - 1\right) = 5.6\times10^{-5}\,\text{F} = \boxed{56\,\mu\text{F}}$$

6. The total charge will be conserved, and the final potential difference across the capacitors will be the same.

$$Q_0 = Q_1 + Q_2 \;;\; V_1 = V_2 \;\rightarrow\; \frac{Q_1}{C_1} = \frac{Q_2}{C_2} = \frac{Q_0 - Q_1}{C_2} \;\rightarrow\; \boxed{Q_1 = Q_0\frac{C_1}{C_1 + C_2}}$$

$$Q_2 = Q_0 - Q_1 = Q_0 - Q_0\frac{C_1}{C_1 + C_2} = \boxed{Q_2 = Q_0\left(\frac{C_2}{C_1 + C_2}\right)}$$

$$V_1 = V_2 = \frac{Q_1}{C_1} = \frac{Q_0\dfrac{C_1}{C_1 + C_2}}{C_1} = \boxed{V = \frac{Q_0}{C_1 + C_2}}$$

7. The work to move the charge between the capacitor plates is $W = qV$, where V is the voltage difference between the plates, assuming that $q \ll Q$ so that the charge on the capacitor does not change appreciably. The charge is then found from Eq. 24-1. The assumption that $q \ll Q$ is justified.

$$W = qV = q\left(\frac{Q}{C}\right) \;\rightarrow\; Q = \frac{CW}{q} = \frac{\left(15\,\mu\text{F}\right)\left(15\,\text{J}\right)}{0.20\,\text{mC}} = \boxed{1.1\,\text{C}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8. (*a*) The total charge on the combination of capacitors is the sum of the charges on the two individual capacitors, since there is no battery connected to them to supply additional charge, and there is no neutralization of charge by combining positive and negative charges. The voltage across each capacitor must be the same after they are connected, since each capacitor plate is connected to a corresponding plate on the other capacitor by a constant-potential connecting wire. Use the total charge and the fact of equal potentials to find the charge on each capacitor and the common potential difference.

$$Q_{1\,\text{initial}} = C_1 V_{1\,\text{initial}} \qquad Q_{2\,\text{initial}} = C_2 V_{2\,\text{initial}} \qquad Q_{1\,\text{final}} = C_1 V_{\text{final}} \qquad Q_{2\,\text{final}} = C_2 V_{\text{final}}$$

$$Q_{\text{Total}} = Q_{1\,\text{initial}} + Q_{2\,\text{initial}} = Q_{1\,\text{final}} + Q_{2\,\text{final}} = C_1 V_{1\,\text{initial}} + C_2 V_{2\,\text{initial}} = C_1 V_{\text{final}} + C_2 V_{\text{final}} \quad \rightarrow$$

$$V_{\text{final}} = \frac{C_1 V_{1\,\text{initial}} + C_2 V_{2\,\text{initial}}}{C_1 + C_2} = \frac{\left(2.70\times10^{-6}\,\text{F}\right)\left(475\,\text{V}\right) + \left(4.00\times10^{-6}\,\text{F}\right)\left(525\,\text{V}\right)}{\left(6.70\times10^{-6}\,\text{F}\right)}$$

$$= 504.85\,\text{V} \approx \boxed{505\,\text{V}} = V_1 = V_2$$

$$Q_{1\,\text{final}} = C_1 V_{\text{final}} = \left(2.70\times10^{-6}\,\text{F}\right)\left(504.85\,\text{V}\right) = \boxed{1.36\times10^{-3}\,\text{C}}$$

$$Q_{2\,\text{final}} = C_2 V_{\text{final}} = \left(4.00\times10^{-6}\,\text{F}\right)\left(504.85\,\text{V}\right) = \boxed{2.02\times10^{-3}\,\text{C}}$$

(*b*) By connecting plates of opposite charge, the total charge will be the difference of the charges on the two individual capacitors. Once the charges have equalized, the two capacitors will again be at the same potential.

$$Q_{1\,\text{initial}} = C_1 V_{1\,\text{initial}} \qquad Q_{2\,\text{initial}} = C_2 V_{2\,\text{initial}} \qquad Q_{1\,\text{final}} = C_1 V_{\text{final}} \qquad Q_{2\,\text{final}} = C_2 V_{\text{final}}$$

$$Q_{\text{Total}} = \left|Q_{1\,\text{initial}} - Q_{2\,\text{initial}}\right| = Q_{1\,\text{final}} + Q_{2\,\text{final}} \quad \rightarrow \quad \left|C_1 V_{1\,\text{initial}} - C_2 V_{2\,\text{initial}}\right| = C_1 V_{\text{final}} + C_2 V_{\text{final}} \quad \rightarrow$$

$$V_{\text{final}} = \frac{\left|C_1 V_{1\,\text{initial}} - C_2 V_{2\,\text{initial}}\right|}{C_1 + C_2} = \frac{\left|\left(2.70\times10^{-6}\,\text{F}\right)\left(475\,\text{V}\right) - \left(4.00\times10^{-6}\,\text{F}\right)\left(525\,\text{V}\right)\right|}{\left(6.70\times10^{-6}\,\text{F}\right)}$$

$$= 122.01\,\text{V} \approx \boxed{120\,\text{V}} = V_1 = V_2$$

$$Q_{1\,\text{final}} = C_1 V_{\text{final}} = \left(2.70\times10^{-6}\,\text{F}\right)\left(122.01\,\text{V}\right) = \boxed{3.3\times10^{-4}\,\text{C}}$$

$$Q_{2\,\text{final}} = C_2 V_{\text{final}} = \left(4.00\times10^{-6}\,\text{F}\right)\left(122.01\,\text{V}\right) = \boxed{4.9\times10^{-4}\,\text{C}}$$

9. Use Eq. 24-1.

$$\Delta Q = C\Delta V \;;\; t = \frac{\Delta Q}{\Delta Q/\Delta t} = \frac{C\Delta V}{\Delta Q/\Delta t} = \frac{\left(1200\,\text{F}\right)\left(6.0\,\text{V}\right)}{1.0\times10^{-3}\,\text{C/s}} = 7.2\times10^{6}\,\text{s}\left(\frac{1\,\text{d}}{86,400\,\text{s}}\right) = \boxed{83\,\text{d}}$$

10. (*a*) The absolute value of the charge on each plate is given by Eq. 24-1. The plate with electrons has a net negative charge.

$$Q = CV \quad \rightarrow \quad N\left(-e\right) = -CV \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$N = \frac{CV}{e} = \frac{\left(35\times10^{-15}\,\text{F}\right)\left(1.5\,\text{V}\right)}{1.60\times10^{-19}\,\text{C}} = 3.281\times10^{5} \approx \boxed{3.3\times10^{5}\,\text{electrons}}$$

(*b*) Since the charge is directly proportional to the potential difference, a 1.0% decrease in potential difference corresponds to a 1.0% decrease in charge.

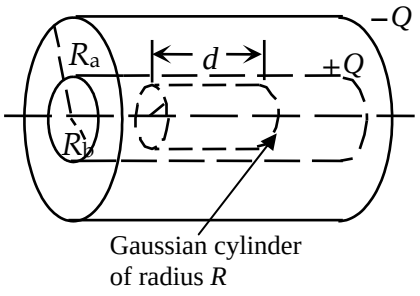
$\Delta Q = 0.01Q$;

$$\Delta t = \frac{\Delta Q}{\Delta Q/\Delta t} = \frac{0.01Q}{\Delta Q/\Delta t} = \frac{0.01CV}{\Delta Q/\Delta t} = \frac{0.01\left(35\times10^{-15}\,\text{F}\right)\left(1.5\,\text{V}\right)}{0.30\times10^{-15}\,\text{C/s}} = 1.75\,\text{s} \approx \boxed{1.8\,\text{s}}$$

11. Use Eq. 24-2.

$$C = \varepsilon_0\frac{A}{d} \quad\rightarrow\quad A = \frac{Cd}{\varepsilon_0} = \frac{\left(0.40\times10^{-6}\,\text{F}\right)\left(2.8\times10^{-3}\,\text{m}\right)}{\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\bullet\text{m}^2\right)} = 126.6\,\text{m}^2 \approx \boxed{130\,\text{m}^2}$$

If the capacitor plates were square, they would be about 11.2 m on a side.



12. The capacitance per unit length of a coaxial cable is derived in Example 24-2

$$\frac{C}{\ell} = \frac{2\pi\varepsilon_0}{\ln\left(R_{\text{outside}}/R_{\text{inside}}\right)} = \frac{2\pi\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\bullet\text{m}^2\right)}{\ln\left(5.0\,\text{mm}/1.0\,\text{mm}\right)} = \boxed{3.5\times10^{-11}\,\text{F/m}}$$

13. Inserting the potential at the surface of a spherical conductor into Eq. 24.1 gives the capacitance of a conducting sphere. Then inserting the radius of the Earth yields the Earth's capacitance.

$$C = \frac{Q}{V} = \frac{Q}{\left(Q/4\pi\varepsilon_0 r\right)} = 4\pi\varepsilon_0 r = 4\pi\left(8.85\times10^{-12}\,\text{F/m}\right)\left(6.38\times10^{6}\,\text{m}\right) = \boxed{7.10\times10^{-4}\,\text{F}}$$

14. From the symmetry of the charge distribution, any electric field must be radial, away from the cylinder axis, and its magnitude must be independent of the location around the axis (for a given radial location). We assume the cylinders have charge of magnitude Q in a length ℓ. Choose a Gaussian cylinder of length d and radius R, centered on the capacitor's axis, with $d \ll \ell$ and the Gaussian cylinder far away from both ends of the capacitor. On the ends of this cylinder, $\vec{\mathbf{E}} \perp d\vec{\mathbf{A}}$ and so there is no flux through the ends. On the curved side of the cylinder, the field has a constant magnitude and $\vec{\mathbf{E}} \parallel d\vec{\mathbf{A}}$. Thus $\vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = EdA$. Write Gauss's law.

$$\oiint \vec{\mathbf{E}}\bullet d\vec{\mathbf{A}} = E_{\substack{\text{curved}\\\text{walls}}} A_{\substack{\text{curved}\\\text{walls}}} = E\left(2\pi Rd\right) = \frac{Q_{\text{encl}}}{\varepsilon_0}$$

For $R < R_b$, $Q_{\text{encl}} = 0 \quad\rightarrow\quad E\left(2\pi Rd\right)\varepsilon_0 = 0 \quad\rightarrow\quad E = 0.$

For $R > R_a$, $Q_{\text{encl}} = \frac{Q}{\ell}d + \frac{-Q}{\ell}d = 0$, and so $Q_{\text{encl}} = 0 \quad\rightarrow\quad E\left(2\pi Rd\right)\varepsilon_0 = 0 \quad\rightarrow\quad E = 0.$

15. We assume there is a uniform electric field between the capacitor plates, so that $V = Ed$, and then use Eqs. 24-1 and 24-2.

$$Q_{\max} = CV_{\max} = \varepsilon_0\frac{A}{d}\left(E_{\max}d\right) = \varepsilon_0 AE_{\max} = \left(8.85\times10^{-12}\,\text{F/m}\right)\left(6.8\times10^{-4}\,\text{m}^2\right)\left(3.0\times10^{6}\,\text{V/m}\right)$$

$$= \boxed{1.8\times10^{-8}\,\text{C}}$$

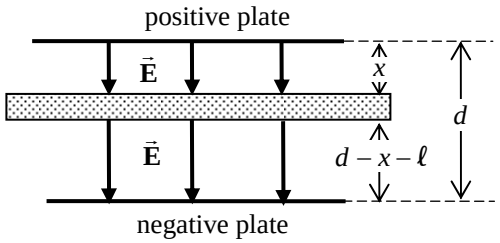
16. We assume there is a uniform electric field between the capacitor plates, so that $V = Ed$, and then use Eqs. 24-1 and 24-2.



$$Q = CV = \varepsilon_0 \frac{A}{d}(Ed) = \varepsilon_0 AE = \left(8.85\times10^{-12}\,\text{F/m}\right)\left(21.0\times10^{-4}\,\text{m}^2\right)\left(4.80\times10^{5}\,\text{V/m}\right)$$

$$= \boxed{8.92\times10^{-9}\,\text{C}}$$

17. We assume there is a uniform electric field between the capacitor plates, so that $V = Ed$, and then use Eqs. 24-1 and 24-2.

$$Q = CV = CEd \;\rightarrow\; E = \frac{Q}{Cd} = \frac{92\times10^{-6}\,\text{C}}{\left(0.80\times10^{-6}\,\text{F}\right)\left(2.0\times10^{-3}\,\text{m}\right)} = \boxed{5.8\times10^{4}\,\text{V/m}}$$

18. (*a*) The uncharged plate will polarize so that negative charge will be drawn towards the positive capacitor plate, and positive charge will be drawn towards the negative capacitor plate. The same charge will be on each face of the plate as on the original capacitor plates. The same electric field will be in the gaps as before the plate was inserted. Use that electric field to determine the potential difference between the two original plates, and the new capacitance. Let x be the distance from one original plate to the nearest face of the sheet, and so $d - \ell - x$ is the distance from the other original plate to the other face of the sheet.

$$E = \frac{\sigma}{\varepsilon_0} = \frac{Q}{A\varepsilon_0} \;;\; V_1 = Ex = \frac{Qx}{A\varepsilon_0} \;;\; V_2 = E\left(d-\ell-x\right) = \frac{Q\left(d-\ell-x\right)}{A\varepsilon_0}$$

$$\Delta V = V_1 + V_2 = \frac{Qx}{A\varepsilon_0} + \frac{Q\left(d-\ell-x\right)}{A\varepsilon_0} = \frac{Q\left(d-\ell\right)}{A\varepsilon_0} = \frac{Q}{C} \;\rightarrow\; C = \boxed{\varepsilon_0 \frac{A}{\left(d-\ell\right)}}$$

(*b*) $$C_{\text{initial}} = \varepsilon_0 \frac{A}{d} \;;\; C_{\text{final}} = \varepsilon_0 \frac{A}{\left(d-\ell\right)} \;;\; \frac{C_{\text{final}}}{C_{\text{initial}}} = \frac{\varepsilon_0 \dfrac{A}{\left(d-\ell\right)}}{\varepsilon_0 \dfrac{A}{d}} = \frac{d}{d-\ell} = \frac{d}{d-0.40d} = \frac{1}{0.60} = \boxed{1.7}$$

19. (*a*) The distance between plates is obtained from Eq. 24-2.

$$C = \frac{\varepsilon_0 A}{x} \;\rightarrow\; x = \frac{\varepsilon_0 A}{C}$$

Inserting the maximum capacitance gives the minimum plate separation and the minimum capacitance gives the maximum plate separation.

$$x_{\text{min}} = \frac{\varepsilon_0 A}{C_{\text{max}}} = \frac{\left(8.85\,\text{pF/m}\right)\left(25\times10^{-6}\,\text{m}^2\right)}{1000.0\times10^{-12}\,\text{F}} = 0.22\,\mu\text{m}$$

$$x_{\text{max}} = \frac{\varepsilon_o A}{C_{\text{min}}} = \frac{\left(8.85\,\text{pF/m}\right)\left(25\times10^{-6}\,\text{m}^2\right)}{1.0\,\text{pF}} = 0.22\,\text{mm} = 220\,\mu\text{m}$$

So $\boxed{0.22\,\mu\text{m} \le x \le 220\,\mu\text{m}}$.

(*b*) Differentiating the distance equation gives the approximate uncertainty in distance.

$$\Delta x \approx \frac{dx}{dC}\Delta C = \frac{d}{dC}\left[\frac{\varepsilon_0 A}{C}\right]\Delta C = -\frac{\varepsilon_0 A}{C^2}\Delta C .$$

The minus sign indicates that the capacitance increases as the plate separation decreases. Since only the magnitude is desired, the minus sign can be dropped. The uncertainty is finally written in terms of the plate separation using Eq. 24-2.

$$\Delta x \approx \frac{\varepsilon_0 A}{\left(\frac{\varepsilon_0 A}{x}\right)^2}\Delta C = \boxed{\frac{x^2 \Delta C}{\varepsilon_0 A}}$$

(*c*) The percent uncertainty in distance is obtained by dividing the uncertainty by the separation distance.

$$\frac{\Delta x_{\min}}{x_{\min}} \times 100\% = \frac{x_{\min}\Delta C}{\varepsilon_o A} \times 100\% = \frac{(0.22\,\mu\text{m})(0.1\,\text{pF})(100\%)}{(8.85\,\text{pF/m})(25\,\text{mm}^2)} = \boxed{0.01\%}$$

$$\frac{\Delta x_{\max}}{x_{\max}} \times 100\% = \frac{x_{\max}\Delta C}{\varepsilon_o A} \times 100\% = \frac{(0.22\,\text{mm})(0.1\,\text{pF})(100\%)}{(8.85\,\text{pF/m})(25\,\text{mm}^2)} = \boxed{10\%}$$

20. The goal is to have an electric field of strength E_S at a radial distance of $5.0\,R_b$ from the center of the cylinder. Knowing the electric field at a specific distance allows us to calculate the linear charge density on the inner cylinder. From the linear charge density and the capacitance we can find the potential difference needed to create the field. From the cylindrically symmetric geometry and Gauss's law, the field in between the cylinders is given by $E = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{R}$. The capacitance of a cylindrical capacitor is given in Example 24-2.

$$E(R = 5.0R_b) = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{(5.0R_b)} = E_S \quad \rightarrow \quad \lambda = 2\pi\varepsilon_0 (5.0R_b) E_S = \frac{Q}{\ell}$$

$$Q = CV \quad \rightarrow \quad V = \frac{Q}{C} = \frac{Q}{\frac{2\pi\varepsilon_0 \ell}{\ln(R_a/R_b)}} = \frac{Q}{\ell}\frac{\ln(R_a/R_b)}{2\pi\varepsilon_0} = \left[2\pi\varepsilon_0 (5.0R_b) E_S\right]\frac{\ln(R_a/R_b)}{2\pi\varepsilon_0}$$

$$= (5.0R_b) E_S \ln(R_a/R_b) = \left[5.0\left(1.0\times10^{-4}\,\text{m}\right)\right]\left(2.7\times10^6\,\text{N/C}\right)\ln\left(\frac{0.100\,\text{m}}{1.0\times10^{-4}\,\text{m}}\right) = \boxed{9300\,\text{V}}$$

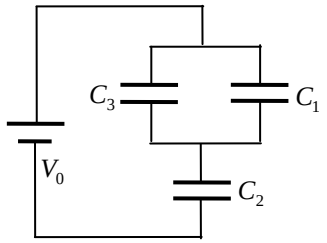
21. To reduce the net capacitance, another capacitor must be added in series.

$$\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2} \quad \rightarrow \quad \frac{1}{C_2} = \frac{1}{C_{eq}} - \frac{1}{C_1} = \frac{C_1 - C_{eq}}{C_1 C_{eq}} \quad \rightarrow$$

$$C_2 = \frac{C_1 C_{eq}}{C_1 - C_{eq}} = \frac{\left(2.9\times10^{-9}\,\text{F}\right)\left(1.6\times10^{-9}\,\text{F}\right)}{\left(2.9\times10^{-9}\,\text{F}\right) - \left(1.6\times10^{-9}\,\text{F}\right)} = 3.57\times10^{-9}\,\text{F} \approx \boxed{3600\,\text{pF}}$$

Yes, an existing connection needs to be broken in the process. One of the connections of the original capacitor to the circuit must be disconnected in order to connect the additional capacitor in series.

22. (*a*) Capacitors in parallel add according to Eq. 24-3.



$$C_{eq} = C_1 + C_2 + C_3 + C_4 + C_5 + C_6 = 6\left(3.8\times10^{-6}\,\text{F}\right) = \boxed{2.28\times10^{-5}\,\text{F}} = 22.8\,\mu\text{F}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Capacitors in series add according to Eq. 24-4.

$$C_{\text{eq}} = \left(\frac{1}{C_1}+\frac{1}{C_2}+\frac{1}{C_3}+\frac{1}{C_4}+\frac{1}{C_5}+\frac{1}{C_6}\right)^{-1} = \left(\frac{6}{3.8\times10^{-6}\,\text{F}}\right)^{-1} = \frac{3.8\times10^{-6}\,\text{F}}{6} = \boxed{6.3\times10^{-7}\,\text{F}}$$
$$= 0.63\,\mu\text{F}$$

23. We want a small voltage drop across C_1. Since $V = Q/C$, if we put the smallest capacitor in series with the battery, there will be a large voltage drop across it. Then put the two larger capacitors in parallel, so that their equivalent capacitance is large and therefore will have a small voltage drop across them. So put C_1 and C_3 in parallel with each other, and then put that combination in series with C_2. See the diagram. To calculate the voltage across C_1, find the equivalent capacitance and the net charge. That charge is used to find the voltage drop across C_2, and then that voltage is subtracted from the battery voltage to find the voltage across the parallel combination.

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_2}+\frac{1}{C_1+C_3} = \frac{C_1+C_2+C_3}{C_2(C_1+C_3)} \;\rightarrow\; C_{\text{eq}} = \frac{C_2(C_1+C_3)}{C_1+C_2+C_3} \;;\; Q_{\text{eq}} = C_{\text{eq}}V_0 \;;\; V_2 = \frac{Q_2}{C_2} = \frac{Q_{\text{eq}}}{C_2} \;;$$

$$V_1 = V_0 - V_2 = V_0 - \frac{Q_{\text{eq}}}{C_2} = V_0 - \frac{C_{\text{eq}}V_0}{C_2} = V_0 - \frac{\dfrac{C_2(C_1+C_3)}{C_1+C_2+C_3}V_0}{C_2} = \frac{C_2}{C_1+C_2+C_3}V_0 = \frac{1.5\,\mu\text{F}}{6.5\,\mu\text{F}}(12\,\text{V})$$
$$= \boxed{2.8\,\text{V}}$$

24. The capacitors are in parallel, and so the potential is the same for each capacitor, and the total charge on the capacitors is the sum of the individual charges. We use Eqs. 24-1 and 24-2.

$$Q_1 = C_1V = \varepsilon_0\frac{A_1}{d_1}V \;;\; Q_2 = C_2V = \varepsilon_0\frac{A_2}{d_2}V \;;\; Q_3 = C_3V = \varepsilon_0\frac{A_3}{d_3}V$$

$$Q_{\text{total}} = Q_1+Q_2+Q_3 = \varepsilon_0\frac{A_1}{d_1}V + \varepsilon_0\frac{A_2}{d_2}V + \varepsilon_0\frac{A_3}{d_3}V = \left(\varepsilon_0\frac{A_1}{d_1}+\varepsilon_0\frac{A_2}{d_2}+\varepsilon_0\frac{A_3}{d_3}\right)V$$

$$C_{\text{net}} = \frac{Q_{\text{total}}}{V} = \frac{\left(\varepsilon_0\dfrac{A_1}{d_1}+\varepsilon_0\dfrac{A_2}{d_2}+\varepsilon_0\dfrac{A_3}{d_3}\right)V}{V} = \left(\varepsilon_0\frac{A_1}{d_1}+\varepsilon_0\frac{A_2}{d_2}+\varepsilon_0\frac{A_3}{d_3}\right) = C_1+C_2+C_3$$

25. Capacitors in parallel add linearly, and so adding a capacitor in parallel will increase the net capacitance without removing the $5.0\,\mu\text{F}$ capacitor.

$$5.0\,\mu\text{F} + C = 16\,\mu\text{F} \;\rightarrow\; C = \boxed{11\,\mu\text{F connected in parallel}}$$

26. (*a*) The two capacitors are in parallel. Both capacitors have their high voltage plates at the same potential (the middle plate), and both capacitors have their low voltage plates at the same potential (the outer plates, which are connected).

(*b*) The capacitance of two capacitors in parallel is the sum of the individual capacitances.

$$C = C_1 + C_2 = \frac{\varepsilon_0 A}{d_1} + \frac{\varepsilon_0 A}{d_2} = \boxed{\varepsilon_0 A\left(\frac{1}{d_1}+\frac{1}{d_2}\right)} = \varepsilon_0 A\left(\frac{d_1+d_2}{d_1 d_2}\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) Let $\ell = d_1 + d_2 = \text{constant}$. Then $C = \dfrac{\varepsilon_0 A\ell}{d_1 d_2} = \dfrac{\varepsilon_0 A\ell}{d_1(\ell - d_1)}$. We see that $C \to \infty$ as $d_1 \to 0$ or $d_1 \to \ell$ (which is $d_2 \to 0$). Of course, a real capacitor would break down as the plates got too close to each other. To find the minimum capacitance, set $\dfrac{dC}{d(d_1)} = 0$ and solve for d_1.

$$\frac{dC}{d(d_1)} = \frac{d}{d(d_1)}\left[\frac{\varepsilon_0 A\ell}{d_1\ell - d_1^2}\right] = \varepsilon_0 A\ell \frac{(\ell - 2d_1)}{(d_1\ell - d_1^2)^2} = 0 \quad \rightarrow \quad d_1 = \tfrac{1}{2}\ell = d_2$$

$$C_{\min} = \varepsilon_0 A\left(\frac{d_1 + d_2}{d_1 d_2}\right)_{d_1 = \frac{1}{2}\ell} = \varepsilon_0 A\left(\frac{\ell}{(\frac{1}{2}\ell)(\frac{1}{2}\ell)}\right) = \varepsilon_0 A\left(\frac{4}{\ell}\right) = \varepsilon_0 A\left(\frac{4}{d_1 + d_2}\right)$$

$$\boxed{C_{\min} = \frac{4\varepsilon_0 A}{d_1 + d_2} \; ; \; C_{\max} = \infty}$$

27. The maximum capacitance is found by connecting the capacitors in parallel.

$$C_{\max} = C_1 + C_2 + C_3 = 3.6\times10^{-9}\,\text{F} + 5.8\times10^{-9}\,\text{F} + 1.00\times10^{-8}\,\text{F} = \boxed{1.94\times10^{-8}\,\text{F in parallel}}$$

The minimum capacitance is found by connecting the capacitors in series.

$$C_{\min} = \left(\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}\right)^{-1} = \left(\frac{1}{3.6\times10^{-9}\,\text{F}} + \frac{1}{5.8\times10^{-9}\,\text{F}} + \frac{1}{1.00\times10^{-8}\,\text{F}}\right)^{-1} = \boxed{1.82\times10^{-9}\,\text{F in series}}$$

28. When the capacitors are connected in series, they each have the same charge as the net capacitance.

(*a*) $Q_1 = Q_2 = Q_{\text{eq}} = C_{\text{eq}}V = \left(\dfrac{1}{C_1} + \dfrac{1}{C_2}\right)^{-1} V = \left(\dfrac{1}{0.50\times10^{-6}\,\text{F}} + \dfrac{1}{0.80\times10^{-6}\,\text{F}}\right)^{-1}(9.0\,\text{V})$

$= 2.769\times10^{-6}\,\text{C}$

$$V_1 = \frac{Q_1}{C_1} = \frac{2.769\times10^{-6}\,\text{C}}{0.50\times10^{-6}\,\text{F}} = 5.538\,\text{V} \approx \boxed{5.5\,\text{V}} \qquad V_2 = \frac{Q_2}{C_2} = \frac{2.769\times10^{-6}\,\text{C}}{0.80\times10^{-6}\,\text{F}} = 3.461\,\text{V} \approx \boxed{3.5\,\text{V}}$$

(*b*) $Q_1 = Q_2 = Q_{\text{eq}} = 2.769\times10^{-6}\,\text{C} \approx \boxed{2.8\times10^{-6}\,\text{C}}$

When the capacitors are connected in parallel, they each have the full potential difference.

(*c*) $V_1 = \boxed{9.0\,\text{V}} \qquad V_2 = \boxed{9.0\,\text{V}} \qquad Q_1 = C_1V_1 = (0.50\times10^{-6}\,\text{F})(9.0\,\text{V}) = \boxed{4.5\times10^{-6}\,\text{C}}$

$Q_2 = C_2V_2 = (0.80\times10^{-6}\,\text{F})(9.0\,\text{V}) = \boxed{7.2\times10^{-6}\,\text{C}}$

29. (*a*) From the diagram, we see that C_1 and C_2 are in series. That combination is in parallel with C_3, and then that combination is in series with C_4. Use those combinations to find the equivalent capacitance. We use subscripts to indicate which capacitors have been combined.

$$\frac{1}{C_{12}} = \frac{1}{C} + \frac{1}{C} \quad \rightarrow \quad C_{12} = \tfrac{1}{2}C \; ; \; C_{123} = C_{12} + C_3 = \tfrac{1}{2}C + C = \tfrac{3}{2}C \; ;$$

$$\frac{1}{C_{1234}} = \frac{1}{C_{123}} + \frac{1}{C_4} = \frac{2}{3C} + \frac{1}{C} = \frac{5}{3C} \quad \rightarrow \quad C_{1234} = \boxed{\tfrac{3}{5}C}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The charge on the equivalent capacitor C_{1234} is given by $Q_{1234} = C_{1234}V = \frac{3}{5}CV$. This is the charge on both of the series components of C_{1234}.

$$Q_{123} = \tfrac{3}{5}CV = C_{123}V_{123} = \tfrac{3}{2}CV_{123} \;\rightarrow\; V_{123} = \tfrac{2}{5}V$$

$$Q_4 = \tfrac{3}{5}CV = C_4V_4 \;\rightarrow\; V_4 = \tfrac{3}{5}V$$

The voltage across the equivalent capacitor C_{123} is the voltage across both of its parallel components. Note that the sum of the charges across the two parallel components of C_{123} is the same as the total charge on the two components, $\frac{3}{5}CV$.

$$V_{123} = \tfrac{2}{5}V = V_{12} \;;\; Q_{12} = C_{12}V_{12} = \left(\tfrac{1}{2}C\right)\left(\tfrac{2}{5}V\right) = \tfrac{1}{5}CV$$

$$V_{123} = \tfrac{2}{5}V = V_3 \;;\; Q_3 = C_3V_3 = C\left(\tfrac{2}{5}V\right) = \tfrac{2}{5}CV$$

Finally, the charge on the equivalent capacitor C_{12} is the charge on both of the series components of C_{12}.

$$Q_{12} = \tfrac{1}{5}CV = Q_1 = C_1V_1 \;\rightarrow\; V_1 = \tfrac{1}{5}V \;;\; Q_{12} = \tfrac{1}{5}CV = Q_2 = C_1V_2 \;\rightarrow\; V_2 = \tfrac{1}{5}V$$

Here are all the results, gathered together.

$$\boxed{\begin{array}{l} Q_1 = Q_2 = \tfrac{1}{5}CV \;;\; Q_3 = \tfrac{2}{5}CV \;;\; Q_4 = \tfrac{3}{5}CV \\ V_1 = V_2 = \tfrac{1}{5}V \;;\; V_3 = \tfrac{2}{5}V \;;\; V_4 = \tfrac{3}{5}V \end{array}}$$

30. C_1 and C_2 are in series, so they both have the same charge. We then use that charge to find the voltage across each of C_1 and C_2. Then their combined voltage is the voltage across C_3. The voltage across C_3 is used to find the charge on C_3.

$$Q_1 = Q_2 = 12.4\mu\text{C} \;;\; V_1 = \frac{Q_1}{C_1} = \frac{12.4\mu\text{C}}{16.0\mu\text{F}} = 0.775\,\text{V} \;;\; V_2 = \frac{Q_2}{C_2} = \frac{12.4\mu\text{C}}{16.0\mu\text{F}} = 0.775\,\text{V}$$

$$V_3 = V_1 + V_2 = 1.55\,\text{V} \;;\; Q_3 = C_3V_3 = (16.0\mu\text{F})(1.55\,\text{V}) = 24.8\mu\text{C}$$

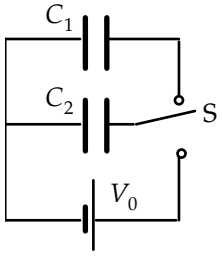
From the diagram, C_4 must have the same charge as the sum of the charges on C_1 and C_3. Then the voltage across the entire combination is the sum of the voltages across C_4 and C_3.

$$Q_4 = Q_1 + Q_3 = 12.4\mu\text{C} + 24.8\mu\text{C} = 37.2\mu\text{C} \;;\; V_4 = \frac{Q_4}{C_4} = \frac{37.2\mu\text{C}}{28.5\mu\text{F}} = 1.31\,\text{V}$$

$$V_{ab} = V_4 + V_3 = 1.31\,\text{V} + 1.55\,\text{V} = 2.86\,\text{V}$$

Here is a summary of all results.

$$\boxed{\begin{array}{l} Q_1 = Q_2 = 12.4\mu\text{C} \;;\; Q_3 = 24.8\mu\text{C} \;;\; Q_4 = 37.2\mu\text{C} \\ V_1 = V_2 = 0.775\,\text{V} \;;\; V_3 = 1.55\,\text{V} \;;\; V_4 = 1.31\,\text{V} \;;\; V_{ab} = 2.86\,\text{V} \end{array}}$$



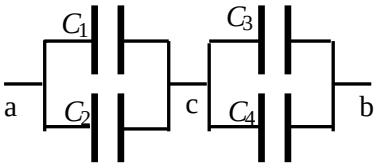
31. When the switch is down the initial charge on C_2 is calculated from Eq. 24-1.

$$Q_2 = C_2V_0$$

When the switch is moved up, charge will flow from C_2 to C_1 until the voltage across the two capacitors is equal.

$$V = \frac{Q_2'}{C_2} = \frac{Q_1'}{C_1} \quad\rightarrow\quad Q_2' = Q_1'\frac{C_2}{C_1}$$

The sum of the charges on the two capacitors is equal to the initial charge on C_2.

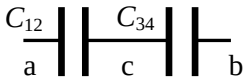


© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

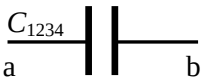
$$Q_2 = Q_2' + Q_1' = Q_1'\frac{C_2}{C_1} + Q_1' = Q_1'\left(\frac{C_2 + C_1}{C_1}\right)$$

Inserting the initial charge in terms of the initial voltage gives the final charges.

$$Q_1'\left(\frac{C_2 + C_1}{C_1}\right) = C_2 V_0 \quad \rightarrow \quad Q_1' = \boxed{\frac{C_1 C_2}{C_2 + C_1} V_0} \;;\; Q_2' = Q_1'\frac{C_2}{C_1} = \boxed{\frac{C_2^2}{C_2 + C} V_0}$$



32. (*a*) From the diagram, we see that C_1 and C_2 are in parallel, and C_3 and C_4 are in parallel. Those two combinations are then in series with each other. Use those combinations to find the equivalent capacitance. We use subscripts to indicate which capacitors have been combined.



$$C_{12} = C_1 + C_2 \;;\; C_{34} = C_3 + C_4 \;;$$

$$\frac{1}{C_{1234}} = \frac{1}{C_{12}} + \frac{1}{C_{34}} = \frac{1}{C_1 + C_2} + \frac{1}{C_3 + C_4} \quad \rightarrow$$

$$C_{1234} = \boxed{\frac{(C_1 + C_2)(C_3 + C_4)}{(C_1 + C_2 + C_3 + C_4)}}$$

(*b*) The charge on the equivalent capacitor C_{1234} is given by $Q_{1234} = C_{1234}V$. This is the charge on both of the series components of C_{1234}. Note that $V_{12} + V_{34} = V$.

$$Q_{12} = C_{1234}V = C_{12}V_{12} \quad \rightarrow \quad V_{12} = \frac{C_{1234}}{C_{12}}V = \frac{\dfrac{(C_1 + C_2)(C_3 + C_4)}{(C_1 + C_2 + C_3 + C_4)}}{C_1 + C_2}V = \frac{(C_3 + C_4)}{(C_1 + C_2 + C_3 + C_4)}V$$

$$Q_{34} = C_{1234}V = C_{34}V_{34} \quad \rightarrow \quad V_{34} = \frac{C_{1234}}{C_{34}}V = \frac{\dfrac{(C_1 + C_2)(C_3 + C_4)}{(C_1 + C_2 + C_3 + C_4)}}{C_3 + C_4}V = \frac{(C_1 + C_2)}{(C_1 + C_2 + C_3 + C_4)}V$$

The voltage across the equivalent capacitor C_{12} is the voltage across both of its parallel components, and the voltage across the equivalent C_{34} is the voltage across both its parallel components.

$$V_{12} = \boxed{V_1 = V_2 = \frac{(C_3 + C_4)}{(C_1 + C_2 + C_3 + C_4)}V} \;;$$

$$C_1V_1 = \boxed{Q_1 = \frac{C_1(C_3 + C_4)}{(C_1 + C_2 + C_3 + C_4)}V} \;;\; C_2V_2 = \boxed{Q_2 = \frac{C_2(C_3 + C_4)}{(C_1 + C_2 + C_3 + C_4)}V}$$

$$V_{34} = \boxed{V_3 = V_2 = \frac{(C_1 + C_2)}{(C_1 + C_2 + C_3 + C_4)}V} \;;$$

$$C_3V_3 = \boxed{Q_3 = \frac{C_3(C_1 + C_2)}{(C_1 + C_2 + C_3 + C_4)}V} \;;\; C_4V_4 = \boxed{Q_4 = \frac{C_4(C_1 + C_2)}{(C_1 + C_2 + C_3 + C_4)}V}$$

33. (*a*) The voltage across C_3 and C_4 must be the same, since they are in parallel.

$$V_3 = V_4 \;\rightarrow\; \frac{Q_3}{C_3} = \frac{Q_4}{C_4} \;\rightarrow\; Q_4 = Q_3\frac{C_4}{C_3} = (23\mu\text{C})\frac{16\mu\text{F}}{8\mu\text{F}} = \boxed{46\mu\text{C}}$$

The parallel combination of C_3 and C_4 is in series with the parallel combination of C_1 and C_2, and so $Q_3 + Q_4 = Q_1 + Q_2$. That total charge then divides between C_1 and C_2 in such a way that $V_1 = V_2$.

$$Q_1 + Q_2 = Q_3 + Q_4 = 69\mu\text{C} \;;\; V_1 = V_2 \;\rightarrow\; \frac{Q_1}{C_1} = \frac{Q_4}{C_4} = \frac{69\mu\text{C} - Q_1}{C_4} \;\rightarrow$$

$$Q_1 = \frac{C_1}{C_4 + C_1}(69\mu\text{C}) = \frac{8.0\mu\text{F}}{24.0\mu\text{F}}(69\mu\text{C}) = \boxed{23\mu\text{C}} \;;\; Q_2 = 69\mu\text{C} - 23\mu\text{C} = \boxed{46\mu\text{C}}$$

Notice the symmetry in the capacitances and the charges.

(*b*) Use Eq. 24-1.

$$V_1 = \frac{Q_1}{C_1} = \frac{23\mu\text{C}}{8.0\mu\text{F}} = 2.875\,\text{V} \approx \boxed{2.9\,\text{V}} \;;\; V_2 = V_1 = \boxed{2.9\,\text{V}}$$

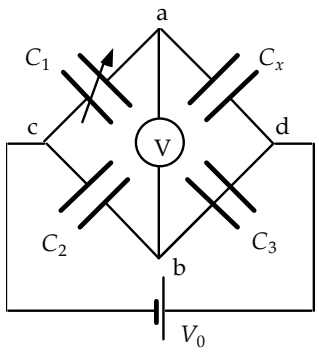
$$V_3 = \frac{Q_3}{C_3} = \frac{23\mu\text{C}}{8.0\mu\text{F}} = 2.875\,\text{V} \approx \boxed{2.9\,\text{V}} \;;\; V_4 = V_3 = \boxed{2.9\,\text{V}}$$

(*c*) $V_{\text{ba}} = V_1 + V_3 = 2.875\,\text{V} + 2.875\,\text{V} = 5.75\text{V} \approx \boxed{5.8\,\text{V}}$

34. We have $C_\text{P} = C_1 + C_2$ and $\frac{1}{C_\text{S}} = \frac{1}{C_1} + \frac{1}{C_2}$. Solve for C_1 and C_2 in terms of C_P and C_S.

$$\frac{1}{C_\text{S}} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{C_1} + \frac{1}{C_\text{P} - C_1} = \frac{(C_\text{P} - C_1) + C_1}{C_1(C_\text{P} - C_1)} = \frac{C_\text{P}}{C_1(C_\text{P} - C_1)} \;\rightarrow$$

$$\frac{1}{C_\text{S}} = \frac{C_\text{P}}{C_1(C_\text{P} - C_1)} \;\rightarrow\; C_1^2 - C_\text{P}C_1 + C_\text{P}C_\text{S} = 0 \;\rightarrow$$



$$C_1 = \frac{C_\text{P} \pm \sqrt{C_\text{P}^2 - 4C_\text{P}C_\text{S}}}{2} = \frac{35.0\mu\text{F} \pm \sqrt{(35.0\mu\text{F})^2 - 4(35.0\mu\text{F})(5.5\mu\text{F})}}{2}$$

$$= 28.2\mu\text{F},\ 6.8\mu\text{F}$$

$$C_2 = C_\text{P} - C_1 = 35.0\mu\text{F} - 28.2\mu\text{F} = 6.8\mu\text{F} \text{ or } 35.0\mu\text{F} - 6.8\mu\text{F} = 28.2\mu\text{F}$$

So the two values are $\boxed{28.2\mu\text{F and } 6.8\mu\text{F}}$.

35. Since there is no voltage between points a and b, we can imagine there being a connecting wire between points a and b. Then capacitors C_1 and C_2 are in parallel, and so have the same voltage. Also capacitors C_3 and C_x are in parallel, and so have the same voltage.

$$V_1 = V_2 \;\rightarrow\; \frac{Q_1}{C_1} = \frac{Q_2}{C_2} \;;\; V_3 = V_x \;\rightarrow\; \frac{Q_3}{C_3} = \frac{Q_x}{C_x}$$

Since no charge flows through the voltmeter, we could also remove it from the circuit and have no change in the circuit. In that case, capacitors C_1 and C_x are in series and so have the same charge. Likewise capacitors C_2 and C_3 are in series, and so have the same charge.

$Q_1 = Q_x \;\; ; \;\; Q_2 = Q_3$

Solve this system of equations for C_x.

$$\frac{Q_3}{C_3} = \frac{Q_x}{C_x} \;\; \rightarrow \;\; C_x = C_3 \frac{Q_x}{Q_3} = C_3 \frac{Q_1}{Q_2} = C_3 \frac{C_1}{C_2} = (4.8\mu\text{F})\left(\frac{8.9\mu\text{F}}{18.0\mu\text{F}}\right) = \boxed{2.4\mu\text{F}}$$

36. The initial equivalent capacitance is the series combination of the two individual capacitances. Each individual capacitor will have the same charge as the equivalent capacitance. The sum of the two initial charges will be the sum of the two final charges, because charge is conserved. The final potential of both capacitors will be equal.

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} \;\; \rightarrow$$

$$C_{\text{eq}} = \frac{C_1 C_2}{C_1 + C_2} \;\; ; \;\; Q_{\text{eq}} = C_{\text{eq}} V_0 = \frac{C_1 C_2}{C_1 + C_2} V_0 = \frac{(3200\,\text{pF})(1800\,\text{pF})}{5000\,\text{pF}}(12.0\,\text{V}) = 13{,}824\,\text{pC}$$

$$Q_{1\,\text{final}} + Q_{2\,\text{final}} = 2Q_{\text{eq}} \;\; ; \;\; V_{1\,\text{final}} = V_{2\,\text{final}} \;\; \rightarrow \;\; \frac{Q_{1\,\text{final}}}{C_1} = \frac{Q_{2\,\text{final}}}{C_2} = \frac{2Q_{\text{eq}} - Q_{1\,\text{final}}}{C_2} \;\; \rightarrow$$

$$Q_{1\,\text{final}} = 2\frac{C_1}{C_1 + C_2} Q_{\text{eq}} = 2\frac{3200\,\text{pF}}{5000\,\text{pF}}(13{,}824\,\text{pC}) = 17{,}695\,\text{pC} \approx \boxed{1.8 \times 10^{-8}\,\text{C}}$$

$$Q_{2\,\text{final}} = 2Q_{\text{eq}} - Q_{1\,\text{final}} = 2(13{,}824\,\text{pC}) - 17{,}695\,\text{pC} = 9953\,\text{pC} \approx \boxed{1.0 \times 10^{-8}\,\text{C}}$$

37. (*a*) The series capacitors add reciprocally, and then the parallel combination is found by adding linearly.

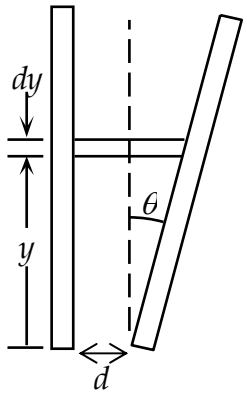
$$C_{\text{eq}} = C_1 + \left(\frac{1}{C_2} + \frac{1}{C_3}\right)^{-1} = C_1 + \left(\frac{C_3}{C_2 C_3} + \frac{C_2}{C_2 C_3}\right)^{-1} = C_1 + \left(\frac{C_2 + C_3}{C_2 C_3}\right)^{-1} = \boxed{C_1 + \frac{C_2 C_3}{C_2 + C_3}}$$

(*b*) For each capacitor, the charge is found by multiplying the capacitance times the voltage. For C_1, the full 35.0 V is across the capacitance, so $Q_1 = C_1 V = (24.0 \times 10^{-6}\,\text{F})(35.0\,\text{V}) =$ $\boxed{8.40 \times 10^{-4}\,\text{C}}$. The equivalent capacitance of the series combination of C_2 and C_3 has the full 35.0 V across it, and the charge on the series combination is the same as the charge on each of the individual capacitors.

$$C_{\text{eq}} = \left(\frac{1}{C} + \frac{1}{C/2}\right)^{-1} = \frac{C}{3} \qquad Q_{\text{eq}} = C_{\text{eq}} V = \tfrac{1}{3}(24.0 \times 10^{-6}\,\text{F})(35.0\,\text{V}) = \boxed{2.80 \times 10^{-4}\,\text{C}} = Q_2 = Q_3$$

38. From the circuit diagram, we see that C_1 is in parallel with the voltage, and so $\boxed{V_1 = 24\,\text{V}}$.

Capacitors C_2 and C_3 both have the same charge, so their voltages are inversely proportional to their capacitance, and their voltages must total to 24.0 V.



$$Q_2 = Q_3 \;\; \rightarrow \;\; C_2 V_2 = C_3 V_3 \;\; ; \;\; V_2 + V_3 = V$$

$$V_2 + \frac{C_2}{C_3} V_2 = V \;\; \rightarrow \;\; V_2 = \frac{C_3}{C_2 + C_3} V = \frac{4.00\mu\text{F}}{7.00\mu\text{F}}(24.0\,\text{V}) = \boxed{13.7\,\text{V}}$$

$$V_3 = V - V_2 = 24.0\,\text{V} - 13.7\,\text{V} = \boxed{10.3\,\text{V}}$$

39. For an infinitesimal area element of the capacitance a distance y up from the small end, the distance between the plates is $d + x = d + y\tan\theta \approx d + y\,\theta$.

Since the capacitor plates are square, they are of dimension $\sqrt{A}\times\sqrt{A}$, and the area of the infinitesimal strip is $dA = \sqrt{A}\,dy$. The infinitesimal capacitance dC of the strip is calculated, and then the total capacitance is found by adding together all of the infinitesimal capacitances, in parallel with each other.

$$C = \varepsilon_0\frac{A}{d} \quad\rightarrow\quad dC = \varepsilon_0\frac{dA}{d+y\,\theta} = \varepsilon_0\frac{\sqrt{A}\,dy}{d+y\,\theta}$$

$$C = \int dC = \int_0^{\sqrt{A}} \varepsilon_0\frac{\sqrt{A}\,dy}{d+y\,\theta} = \frac{\varepsilon_0\sqrt{A}}{\theta}\ln\left(d+y\,\theta\right)\Big|_0^{\sqrt{A}}$$

$$= \frac{\varepsilon_0\sqrt{A}}{\theta}\left[\ln\left(d+\theta\sqrt{A}\right) - \ln d\right] = \frac{\varepsilon_0\sqrt{A}}{\theta}\ln\left(\frac{d+\theta\sqrt{A}}{d}\right) = \frac{\varepsilon_0\sqrt{A}}{\theta}\ln\left(1+\frac{\theta\sqrt{A}}{d}\right)$$

We use the approximation from page A-1 that $\ln(1+x) \approx x - \frac{1}{2}x^2$.

$$C = \frac{\varepsilon_0\sqrt{A}}{\theta}\ln\left(1+\frac{\theta\sqrt{A}}{d}\right) = \frac{\varepsilon_0\sqrt{A}}{\theta}\left[\frac{\theta\sqrt{A}}{d} - \tfrac{1}{2}\left(\frac{\theta\sqrt{A}}{d}\right)^2\right] = \boxed{\frac{\varepsilon_0 A}{d}\left(1-\frac{\theta\sqrt{A}}{2d}\right)}$$

40. No two capacitors are in series or in parallel in the diagram, and so we may not simplify by that method. Instead use the hint as given in the problem. We consider point a as the higher voltage. The equivalent capacitance must satisfy $Q_{\text{tot}} = C_{\text{eq}}V$.

(*a*) The potential between a and b can be written in three ways. Alternate but equivalent expressions are shown in parentheses.

$$V = V_2 + V_1 \;;\; V = V_2 + V_3 + V_4 \;;\; V = V_5 + V_4 \quad (V_2 + V_3 = V_5 \;;\; V_3 + V_4 = V_1)$$

There are also three independent charge relationships. Alternate but equivalent expressions are shown in parentheses. Convert the charge expressions to voltage – capacitance expression.

$$Q_{\text{tot}} = Q_2 + Q_5 \quad ;\; Q_{\text{tot}} = Q_4 + Q_1 \quad ;\; Q_2 = Q_1 + Q_3 \quad (Q_4 = Q_3 + Q_5)$$

$$C_{\text{eq}}V = C_2V_2 + C_5V_5 \;;\; C_{\text{eq}}V = C_4V_4 + C_1V_1 \;;\; C_2V_2 = C_1V_1 + C_3V_3$$

We have a set of six equations: $V = V_2 + V_1$ (1) ; $V = V_2 + V_3 + V_4$ (2) ; $V = V_5 + V_4$ (3)

$$C_{\text{eq}}V = C_2V_2 + C_5V_5 \;(4)\;;\; C_{\text{eq}}V = C_4V_4 + C_1V_1 \;(5)\;;\; C_2V_2 = C_1V_1 + C_3V_3 \;(6)$$

Solve for C_{eq} as follows.

(i) From Eq. (1), $V_1 = V - V_2$. Rewrite equations (5) and (6). V_1 has been eliminated.

$$C_{\text{eq}}V = C_4V_4 + C_1V - C_1V_2 \;(5)\;;\; C_2V_2 = C_1V - C_1V_2 + C_3V_3 \;(6)$$

(ii) From Eq. (3), $V_5 = V - V_4$. Rewrite equation (4). V_5 has been eliminated.

$$C_{\text{eq}}V = C_2V_2 + C_5V - C_5V_4 \;(4)$$

(iii) From Eq. (2), $V_3 = V - V_2 - V_4$. Rewrite equation (6). V_3 has been eliminated.

$$C_2V_2 = C_1V - C_1V_2 + C_3V - C_3V_2 - C_3V_4 \;(6) \;\rightarrow$$

$$(C_1 + C_2 + C_3)V_2 + C_3V_4 = (C_1 + C_3)V \;(6)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Here is the current set of equations.

$$C_{eq}V = C_2V_2 + C_5V - C_5V_4 \quad (4)$$

$$C_{eq}V = C_4V_4 + C_1V - C_1V_2 \quad (5)$$

$$(C_1 + C_2 + C_3)V_2 + C_3V_4 = (C_1 + C_3)V \quad (6)$$

(iv) From Eq. (4), $V_4 = \frac{1}{C_5}\left(C_2V_2 + C_5V - C_{eq}V\right)$. Rewrite equations (5) and (6).

$$C_5C_{eq}V = C_4\left[\left(C_2V_2 + C_5V - C_{eq}V\right)\right] + C_5C_1V - C_5C_1V_2 \quad (5)$$

$$C_5\left(C_1 + C_2 + C_3\right)V_2 + C_3\left[\left(C_2V_2 + C_5V - C_{eq}V\right)\right] = C_5\left(C_1 + C_3\right)V \quad (6)$$

(v) Group all terms by common voltage.

$$\left(C_5C_{eq} + C_4C_{eq} - C_4C_5 - C_5C_1\right)V = \left(C_4C_2 - C_5C_1\right)V_2 \quad (5)$$

$$\left[C_5\left(C_1 + C_3\right) + C_3C_{eq} - C_3C_5\right]V = \left[C_5\left(C_1 + C_2 + C_3\right) + C_3C_2\right]V_2 \quad (6)$$

(vi) Divide the two equations to eliminate the voltages, and solve for the equivalent capacitance.

$$\frac{\left(C_5C_{eq} + C_4C_{eq} - C_4C_5 - C_5C_1\right)}{\left[C_5\left(C_1 + C_3\right) + C_3C_{eq} - C_3C_5\right]} = \frac{\left(C_4C_2 - C_5C_1\right)}{\left[C_5\left(C_1 + C_2 + C_3\right) + C_3C_2\right]} \quad \rightarrow$$

$$C_{eq} = \boxed{\frac{C_1C_2C_3 + C_1C_2C_4 + C_1C_2C_5 + C_1C_3C_5 + C_1C_4C_5 + C_2C_3C_4 + C_2C_4C_5 + C_3C_4C_5}{C_1C_3 + C_1C_4 + C_1C_5 + C_2C_3 + C_2C_4 + C_2C_5 + C_3C_4 + C_3C_5}}$$

(*b*) Evaluate with the given data. Since all capacitances are in μF, and the expression involves capacitance cubed terms divided by capacitance squared terms, the result will be in μF.

$$C_{eq} = \frac{C_1C_2C_3 + C_1C_2C_4 + C_1C_2C_5 + C_1C_3C_5 + C_1C_4C_5 + C_2C_3C_4 + C_2C_4C_5 + C_3C_4C_5}{C_1C_3 + C_1C_4 + C_1C_5 + C_2C_3 + C_2C_4 + C_2C_5 + C_3C_4 + C_3C_5}$$

$$= \frac{C_1\left[C_2\left(C_3 + C_4 + C_5\right) + C_5\left(C_3 + C_4\right)\right] + C_4\left(C_2C_3 + C_2C_5 + C_3C_5\right)}{C_1\left(C_3 + C_4 + C_5\right) + C_2\left(C_3 + C_4 + C_5\right) + C_3\left(C_4 + C_5\right)}$$

$$= \frac{(4.5)\left\{(8.0)(17.0) + (4.5)(12.5)\right\} + (8.0)\left[(8.0)(4.5) + (8.0)(4.5) + (4.5)(4.5)\right]}{(4.5)(17.0) + (8.0)(17.0) + (4.5)(12.5)}\ \mu\text{F}$$

$$= \boxed{6.0\mu\text{F}}$$

41. The stored energy is given by Eq. 24-5.

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\left(2.8\times10^{-9}\,\text{F}\right)\left(2200\,\text{V}\right)^2 = \boxed{6.8\times10^{-3}\,\text{J}}$$

42. The energy density is given by Eq. 24-6.

$$u = \tfrac{1}{2}\varepsilon_0E^2 = \tfrac{1}{2}\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\bullet\text{m}^2\right)\left(150\,\text{V/m}\right)^2 = \boxed{1.0\times10^{-7}\,\text{J/m}^3}$$

43. The energy stored is obtained from Eq. 24-5, with the capacitance of Eq. 24-2.

$$U = \frac{Q^2}{2C} = \frac{Q^2d}{2\varepsilon_0A} = \frac{\left(4.2\times10^{-4}\,\text{C}\right)^2\left(0.0013\,\text{m}\right)}{2\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\bullet\text{m}^2\right)\left(0.080\,\text{m}\right)^2} = \boxed{2.0\times10^{3}\,\text{J}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

44. (*a*) The charge is constant, and the tripling of separation reduces the capacitance by a factor of 3.

$$\frac{U_2}{U_1} = \frac{\dfrac{Q^2}{2C_2}}{\dfrac{Q^2}{2C_1}} = \frac{C_1}{C_2} = \frac{\varepsilon_0 \dfrac{A}{d}}{\varepsilon_0 \dfrac{A}{3d}} = \boxed{3}$$

(*b*) The work done is the change in energy stored in the capacitor.

$$U_2 - U_1 = 3U_1 - U_1 = 2U_1 = 2\frac{Q^2}{2C_1} = \frac{Q^2}{\varepsilon_0 \dfrac{A}{d}} = \boxed{\frac{Q^2 d}{\varepsilon_0 A}}$$

45. The equivalent capacitance is formed by C_1 in parallel with the series combination of C_2 and C_3. Then use Eq. 24-5 to find the energy stored.

$$C_{\text{net}} = C_1 + \frac{C_2 C_3}{C_2 + C_3} = C + \frac{C^2}{2C} = \tfrac{3}{2}C$$

$$U = \tfrac{1}{2}C_{\text{net}}V^2 = \tfrac{3}{4}CV^2 = \tfrac{3}{4}\left(22.6\times10^{-6}\,\text{F}\right)\left(10.0\,\text{V}\right)^2 = \boxed{1.70\times10^{-3}\,\text{J}}$$

46. (*a*) Use Eqs. 24-3 and 24-5.

$$U_{\text{parallel}} = \tfrac{1}{2}C_{\text{eq}}V^2 = \tfrac{1}{2}\left(C_1 + C_2\right)V^2 = \tfrac{1}{2}\left(0.65\times10^{-6}\,\text{F}\right)\left(28\,\text{V}\right)^2 = 2.548\times10^{-4}\,\text{J} \approx \boxed{2.5\times10^{-4}\,\text{J}}$$

(*b*) Use Eqs. 24-4 and 24-5.

$$U_{\text{series}} = \tfrac{1}{2}C_{\text{eq}}V^2 = \tfrac{1}{2}\left(\frac{C_1 C_2}{C_1 + C_2}\right)V^2 = \tfrac{1}{2}\left(\frac{\left(0.45\times10^{-6}\,\text{F}\right)\left(0.20\times10^{-6}\,\text{F}\right)}{0.65\times10^{-6}\,\text{F}}\right)\left(28\,\text{V}\right)^2$$

$$= 5.428\times10^{-5}\,\text{J} \approx \boxed{5.4\times10^{-5}\,\text{J}}$$

(*c*) The charge can be found from Eq. 24-5.

$$U = \tfrac{1}{2}QV \;\rightarrow\; Q = \frac{2U}{V} \;\rightarrow\; Q_{\text{parallel}} = \frac{2\left(2.548\times10^{-4}\,\text{J}\right)}{28\,\text{V}} = \boxed{1.8\times10^{-5}\,\text{C}}$$

$$Q_{\text{series}} = \frac{2\left(5.428\times10^{-5}\,\text{J}\right)}{28\,\text{V}} = \boxed{3.9\times10^{-6}\,\text{C}}$$

47. The capacitance of a cylindrical capacitor is given in Example 24-2 as $C = \dfrac{2\pi\varepsilon_0\ell}{\ln\left(R_a/R_b\right)}$.

(*a*) If the charge is constant, the energy can be calculated by $U = \tfrac{1}{2}\dfrac{Q^2}{C}$.

$$\frac{U_2}{U_1} = \frac{\tfrac{1}{2}\dfrac{Q^2}{C_2}}{\tfrac{1}{2}\dfrac{Q^2}{C_1}} = \frac{C_1}{C_2} = \frac{\dfrac{2\pi\varepsilon_0\ell}{\ln\left(R_a/R_b\right)}}{\dfrac{2\pi\varepsilon_0\ell}{\ln\left(3R_a/R_b\right)}} = \boxed{\frac{\ln\left(3R_a/R_b\right)}{\ln\left(R_a/R_b\right)}} > 1$$

The energy comes from the work required to separate the capacitor components.

(*b*) If the voltage is constant, the energy can be calculated by $U = \frac{1}{2}CV^2$.

$$\frac{U_2}{U_1} = \frac{\frac{1}{2}C_2V^2}{\frac{1}{2}C_1V^2} = \frac{C_2}{C_1} = \frac{\dfrac{2\pi\varepsilon_0\ell}{\ln\left(3R_a/R_b\right)}}{\dfrac{2\pi\varepsilon_0\ell}{\ln\left(R_a/R_b\right)}} = \boxed{\frac{\ln\left(R_a/R_b\right)}{\ln\left(3R_a/R_b\right)}} < 1$$

Since the voltage remained constant, and the capacitance decreased, the amount of charge on the capacitor components decreased. Charge flowed back into the battery that was maintaining the constant voltage.

48. (*a*) Before the capacitors are connected, the only stored energy is in the initially-charged capacitor. Use Eq. 24-5.

$$U_1 = \tfrac{1}{2}C_1V_0^2 = \tfrac{1}{2}\left(2.20\times10^{-6}\,\text{F}\right)\left(12.0\,\text{V}\right)^2 = 1.584\times10^{-4}\,\text{J} \approx \boxed{1.58\times10^{-4}\,\text{J}}$$

(*b*) The total charge available is the charge on the initial capacitor. The capacitance changes to the equivalent capacitance of the two capacitors in parallel.

$$Q = Q_1 = C_1V_0 \;;\; C_{\text{eq}} = C_1 + C_2 \;;\; U_2 = \tfrac{1}{2}\frac{Q^2}{C_{\text{eq}}} = \tfrac{1}{2}\frac{C_1^2V_0^2}{C_1+C_2} = \tfrac{1}{2}\frac{\left(2.20\times10^{-6}\,\text{F}\right)^2\left(12.0\,\text{V}\right)^2}{\left(5.70\times10^{-6}\,\text{F}\right)}$$

$$= 6.114\times10^{-5}\,\text{J} \approx \boxed{6.11\times10^{-5}\,\text{J}}$$

(*c*) $\Delta U = U_2 - U_1 = 6.114\times10^{-5}\,\text{J} - 1.584\times10^{-4}\,\text{J} = \boxed{-9.73\times10^{-5}\,\text{J}}$

49. (*a*) With the plate inserted, the capacitance is that of two series capacitors of plate separations $d_1 = x$ and $d_2 = d - \ell - x$.

$$C_i = \left[\frac{x}{\varepsilon_0 A} + \frac{d-x-\ell}{\varepsilon_0 A}\right]^{-1} = \frac{\varepsilon_0 A}{d-\ell}$$

With the plate removed the capacitance is obtained directly from Eq. 24-2.

$$C_f = \frac{\varepsilon_0 A}{d}$$

Since the voltage remains constant the energy of the capacitor will be given by Eq. 24-5 written in terms of voltage and capacitance. The work will be the change in energy as the plate is removed.

$$W = U_f - U_i = \tfrac{1}{2}\left(C_f - C_i\right)V^2$$

$$= \tfrac{1}{2}\left(\frac{\varepsilon_0 A}{d} - \frac{\varepsilon_0 A}{d-\ell}\right)V^2 = \boxed{-\frac{\varepsilon_0 A\ell V^2}{2d\left(d-\ell\right)}}$$

The net work done is negative. Although the person pulling the plate out must do work, charge is returned to the battery, resulting in a net negative work done.

(*b*) Since the charge now remains constant, the energy of the capacitor will be given by Eq. 24-5 written in terms of capacitance and charge.

$$W = \frac{Q^2}{2}\left(\frac{1}{C_f} - \frac{1}{C_i}\right) = \frac{Q^2}{2}\left(\frac{d}{\varepsilon_0 A} - \frac{d-\ell}{\varepsilon_0 A}\right) = \frac{Q^2\ell}{2\varepsilon_0 A}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The original charge is $Q = CV_0 = \dfrac{\varepsilon_0 A}{d-\ell}V_0$ and so $W = \dfrac{\left(\dfrac{\varepsilon_0 A}{d-\ell}V_0\right)^2 \ell}{2\varepsilon_0 A} = \boxed{\dfrac{\varepsilon_0 A V_0^2 \ell}{2(d-\ell)^2}}$.

50. (*a*) The charge remains constant, so we express the stored energy as $U = \frac{1}{2}\dfrac{Q^2}{C} = \frac{1}{2}\dfrac{Q^2 x}{\varepsilon_0 A}$, where x is the separation of the plates. The work required to increase the separation by dx is $dW = Fdx$, where F is the force on one plate exerted by the other plate. That work results in an increase in potential energy, dU.

$$dW = Fdx = dU = \tfrac{1}{2}\frac{Q^2 dx}{\varepsilon_0 A} \quad \rightarrow \quad \boxed{F = \frac{1}{2}\frac{Q^2}{\varepsilon_0 A}}$$

(*b*) We cannot use $F = QE = Q\dfrac{\sigma}{\varepsilon_0} = Q\dfrac{Q}{\varepsilon_0 A} = \dfrac{Q^2}{\varepsilon_0 A}$ because the electric field is due to both plates, and charge cannot put a force on itself by the field it creates. By the symmetry of the geometry, the electric field at one plate, due to just the other plate, is $\frac{1}{2}E$. See Example 24-10.

51. (*a*) The electric field outside the spherical conductor is that of an equivalent point charge at the center of the sphere, so $E = \dfrac{1}{4\pi\varepsilon_0}\dfrac{Q}{r^2}, r > R$. Consider a differential volume of radius *dr*, and volume $dV = 4\pi r^2 dr$, as used in Example 22-5. The energy in that volume is $dU = udV$. Integrate over the region outside the conductor.

$$U = \int dU = \int udV = \tfrac{1}{2}\varepsilon_0 \int E^2 dV = \tfrac{1}{2}\varepsilon_0 \int_R^\infty \left(\frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2}\right)^2 4\pi r^2 dr = \frac{Q^2}{8\pi\varepsilon_0}\int_R^\infty \frac{1}{r^2}dr = -\frac{Q^2}{8\pi\varepsilon_0}\frac{1}{r}\Big|_R^\infty$$

$$= \boxed{\frac{Q^2}{8\pi\varepsilon_0 R}}$$

(*b*) Use Eq. 24-5 with the capacitance of an isolated sphere, from the text immediately after Example 24-3.

$$U = \tfrac{1}{2}\frac{Q^2}{C} = \tfrac{1}{2}\frac{Q^2}{4\pi\varepsilon_0 R} = \boxed{\frac{Q^2}{8\pi\varepsilon_0 R}}$$

(*c*) When there is a charge $q < Q$ on the sphere, the potential of the sphere is $V = \dfrac{1}{4\pi\varepsilon_0}\dfrac{q}{R}$. The work required to add a charge *dq* to the sphere is then $dW = Vdq = \dfrac{1}{4\pi\varepsilon_0}\dfrac{q}{R}dq$. That work increase the potential energy by the same amount, so $dU = dW = Vdq = \dfrac{1}{4\pi\varepsilon_0}\dfrac{q}{R}dq$. Build up the entire charge from 0 to *Q*, calculating the energy as the charge increases.

$$U = \int dU = \int dW = \int Vdq = \int_0^Q \frac{1}{4\pi\varepsilon_0}\frac{q}{R}dq = \frac{1}{4\pi\varepsilon_0 R}\int_0^Q qdq = \boxed{\frac{Q^2}{8\pi\varepsilon_0 R}}$$

52. In both configurations, the voltage across the combination of capacitors is the same. So use $U = \frac{1}{2}CV^2$.

$$U_{\text{P}} = \tfrac{1}{2}C_{\text{P}}V^2 = \tfrac{1}{2}(C_1 + C_2)V^2 \;\; ; \;\; U_{\text{S}} = \tfrac{1}{2}C_{\text{S}}V^2 = \tfrac{1}{2}\frac{C_1C_2}{(C_1 + C_2)}V^2$$

$$U_{\text{P}} = 5\,U_{\text{S}} \;\; \rightarrow \;\; \tfrac{1}{2}(C_1 + C_2)V^2 = 5\left(\tfrac{1}{2}\right)\frac{C_1C_2}{(C_1 + C_2)}V^2 \;\; \rightarrow \;\; (C_1 + C_2)^2 = 5C_1C_2 \;\; \rightarrow$$

$$C_1^2 - 3C_1C_2 + C_2^2 = 0 \;\; \rightarrow \;\; C_1 = \frac{3C_2 \pm \sqrt{9C_2^2 - 4C_2^2}}{2} = C_2\frac{3 \pm \sqrt{5}}{2} \;\; \rightarrow$$

$$\frac{C_1}{C_2} = \boxed{\frac{3+\sqrt{5}}{2}, \frac{3-\sqrt{5}}{2} = 2.62, 0.382}$$

53. First find the ratio of energy requirements for a logical operation in the past to the current energy requirements for a logical operation.

$$\frac{E_{\text{past}}}{E_{\text{present}}} = \frac{N\left(\frac{1}{2}CV^2\right)_{\text{past}}}{N\left(\frac{1}{2}CV^2\right)_{\text{present}}} = \left(\frac{C_{\text{past}}}{C_{\text{present}}}\right)\left(\frac{V_{\text{past}}}{V_{\text{present}}}\right)^2 = \left(\frac{20}{1}\right)\left(\frac{5.0}{1.5}\right)^2 = 220$$

So past operations would have required 220 times more energy. Since 5 batteries in the past were required to hold the same energy as a present battery, it would have taken 1100 times as many batteries in the past. And if it takes 2 batteries for a modern PDA, it would take 2200 batteries to power the PDA in the past. It would not fit in a pocket or purse. The volume of a present-day battery is $V = \pi r^2 \ell = \pi(0.5\,\text{cm})^2(4\,\text{cm}) = 3\,\text{cm}^3$. The volume of 2200 of them would be $6600\,\text{cm}^3$, which would require a cube about 20 cm in side length.

54. Use Eq. 24-8 to calculate the capacitance with a dielectric.

$$C = K\varepsilon_0\frac{A}{d} = (2.2)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\frac{\left(4.2\times10^{-2}\,\text{m}\right)^2}{\left(1.8\times10^{-3}\,\text{m}\right)} = \boxed{1.9\times10^{-11}\,\text{F}}$$

55. The change in energy of the capacitor is obtained from Eq. 24-5 in terms of the constant voltage and the capacitance.

$$\Delta U = U_{\text{f}} - U_{\text{i}} = \tfrac{1}{2}C_0V^2 - \tfrac{1}{2}KC_0V^2 = -\tfrac{1}{2}(K-1)C_0V^2$$

The work done by the battery in maintaining a constant voltage is equal to the voltage multiplied by the change in charge, with the charge given by Eq. 24-1.

$$W_{\text{battery}} = V(Q_{\text{f}} - Q_{\text{i}}) = V(C_0V - KC_0V) = -(K-1)C_0V^2$$

The work done in pulling the dielectric out of the capacitor is equal to the difference between the change in energy of the capacitor and the energy done by the battery.

$$W = \Delta U - W_{\text{battery}} = -\tfrac{1}{2}(K-1)C_0V^2 + (K-1)C_0V^2$$

$$= \tfrac{1}{2}(K-1)C_0V^2 = (3.4-1)\left(8.8\times10^{-9}\,\text{F}\right)\left(100\,\text{V}\right)^2 = \boxed{1.1\times10^{-4}\,\text{J}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

56. We assume the charge and dimensions are the same as in Problem 43. Use Eq. 24-5 with charge and capacitance.

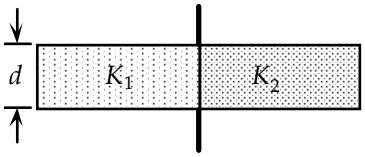
$$U = \tfrac{1}{2}\frac{Q^2}{C} = \tfrac{1}{2}\frac{Q^2}{KC_0} = \tfrac{1}{2}\frac{Q^2 d}{K\varepsilon_0 A} = \tfrac{1}{2}\frac{\left(420\times10^{-6}\,\text{C}\right)^2\left(0.0013\,\text{m}\right)}{(7)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(64\times10^{-4}\,\text{m}^2\right)} = 289.2\,\text{J} \approx \boxed{290\,\text{J}}$$

57. From Problem 10, we have $C = 35\times10^{-15}\,\text{F}$. Use Eq. 24-8 to calculate the area.

$$C = K\varepsilon_0\frac{A}{d} \quad\rightarrow\quad A = \frac{Cd}{K\varepsilon_0} = \frac{\left(35\times10^{-15}\,\text{F}\right)\left(2.0\times10^{-9}\,\text{m}\right)}{(25)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = 3.164\times10^{-13}\,\text{m}^2\left(\frac{10^6\,\mu\text{m}}{1\,\text{m}}\right)^2$$

$$= 0.3164\,\mu\text{m}^2 \approx \boxed{0.32\,\mu\text{m}^2}$$

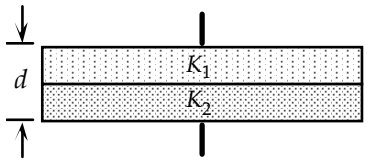
Half of the area of the cell is used for capacitance, so $1.5\,\text{cm}^2$ is available for capacitance. Each capacitor is one "bit."



$$1.5\,\text{cm}^2\left(\frac{10^6\,\mu\text{m}}{10^2\,\text{cm}}\right)^2\left(\frac{1\,\text{bit}}{0.32\,\mu\text{m}^2}\right)\left(\frac{1\,\text{byte}}{8\,\text{bits}}\right) = 5.86\times10^7\,\text{bytes} \approx \boxed{59\,\text{Mbytes}}$$

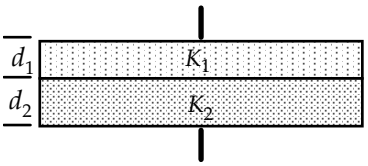
58. The initial charge on the capacitor is $Q_{\text{initial}} = C_{\text{initial}}V$. When the mica is inserted, the capacitance changes to $C_{\text{final}} = KC_{\text{initial}}$, and the voltage is unchanged since the capacitor is connected to the same battery. The final charge on the capacitor is $Q_{\text{final}} = C_{\text{final}}V$.

$$\Delta Q = Q_{\text{final}} - Q_{\text{initial}} = C_{\text{final}}V - C_{\text{initial}}V = (K-1)C_{\text{initial}}V = (7-1)\left(3.5\times10^{-9}\,\text{F}\right)(32\,\text{V})$$



$$= \boxed{6.7\times10^{-7}\,\text{C}}$$

59. The potential difference is the same on each half of the capacitor, so it can be treated as two capacitors in parallel. Each parallel capacitor has half of the total area of the original capacitor.



$$C = C_1 + C_2 = K_1\varepsilon_0\frac{\frac{1}{2}A}{d} + K_2\varepsilon_0\frac{\frac{1}{2}A}{d} = \boxed{\tfrac{1}{2}\left(K_1 + K_2\right)\varepsilon_0\frac{A}{d}}$$

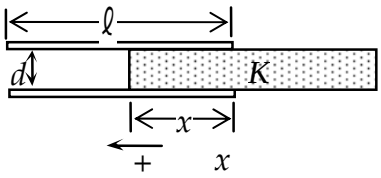
60. The intermediate potential at the boundary of the two dielectrics can be treated as the "low" potential plate of one half and the "high" potential plate of the other half, so we treat it as two capacitors in series. Each series capacitor has half of the inter-plate distance of the original capacitor.

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{\frac{1}{2}d}{K_1\varepsilon_0 A} + \frac{\frac{1}{2}d}{K_2\varepsilon_0 A} = \frac{d}{2\varepsilon_0 A}\frac{K_1 + K_2}{K_1K_2} \quad\rightarrow\quad C = \boxed{\frac{2\varepsilon_0 A}{d}\frac{K_1K_2}{K_1 + K_2}}$$

61. The capacitor can be treated as two series capacitors with the same areas, but different plate separations and dielectrics. Substituting Eq. 24-8 into Eq. 24-4 gives the effective capacitance.

$$C = \left(\frac{1}{C_1} + \frac{1}{C_2}\right)^{-1} = \left(\frac{d_1}{K_1A\varepsilon_0} + \frac{d_2}{K_2A\varepsilon_0}\right)^{-1} = \boxed{\frac{A\varepsilon_0K_1K_2}{d_1K_2 + d_2K_1}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



62. (*a*) Since the capacitors each have the same charge and the same voltage in the initial situation, each has the same capacitance of $C = \dfrac{Q_0}{V_0}$. When the dielectric is inserted, the total charge of $2Q_0$ will not change, but the charge will no longer be divided equally between the two capacitors. Some charge will move from the capacitor without the dielectric (C_1) to the capacitor with the dielectric (C_2). Since the capacitors are in parallel, their voltages will be the same.

$$V_1 = V_2 \quad \rightarrow \quad \frac{Q_1}{C_1} = \frac{Q_2}{C_2} \quad \rightarrow \quad \frac{Q_1}{C} = \frac{2Q_0 - Q_1}{KC} \quad \rightarrow$$

$$Q_1 = \frac{2}{(K+1)}Q_0 = \frac{2}{4.2}Q_0 = \boxed{0.48Q_0} \;\; ; \;\; Q_2 = \boxed{1.52Q_0}$$

(*b*) $$V_1 = V_2 = \frac{Q_1}{C_1} = \frac{0.48Q_0}{Q_0/V_0} = \boxed{0.48V_0} = \frac{Q_2}{C_2} = \frac{1.52Q_0}{3.2\,Q_0/V_0}$$

63. (*a*) We treat this system as two capacitors, one with a dielectric, and one without a dielectric. Both capacitors have their high voltage plates in contact and their low voltage plates in contact, so they are in parallel. Use Eq. 24-2 and 24-8 for the capacitance. Note that *x* is measured from the right edge of the capacitor, and is positive to the left in the diagram.

$$C = C_1 + C_2 = \varepsilon_0 \frac{\ell(\ell - x)}{d} + K\varepsilon_0 \frac{\ell x}{d} = \boxed{\varepsilon_0 \frac{\ell^2}{d}\left[1 + (K-1)\frac{x}{\ell}\right]}$$

(*b*) Both "capacitors" have the same potential difference, so use $U = \frac{1}{2}CV^2$.

$$U = \tfrac{1}{2}(C_1 + C_2)V_0^2 = \boxed{\varepsilon_0 \frac{\ell^2}{2d}\left[1 + (K-1)\frac{x}{\ell}\right]V_0^2}$$

(*c*) We must be careful here. When the voltage across a capacitor is constant and a dielectric is inserted, charge flows from the battery to the capacitor. So the battery will lose energy and the capacitor gain energy as the dielectric is inserted. As in Example 24-10, we assume that work is done by an external agent (W_{nc}) in such a way that the dielectric has no kinetic energy. Then the work-energy principle (Chapter 8) can be expressed as $W_{\text{nc}} = \Delta U$ or $dW_{\text{nc}} = dU$. This is analogous to moving an object vertically at constant speed. To increase (decrease) the gravitational potential energy, positive (negative) work must be done by an outside, non-gravitational source.

In this problem, the potential energy of the voltage source and the potential energy of the capacitor both change as *x* changes. Also note that the change in charge stored on the capacitor is the opposite of the change in charge stored in the voltage supply.

$$dW_{\text{nc}} = dU = dU_{\text{cap}} + dU_{\text{battery}} \quad \rightarrow \quad F_{\text{nc}}dx = d\left(\tfrac{1}{2}CV_0^2\right) + d\left(Q_{\text{battery}}V_0\right) \quad \rightarrow$$

$$F_{\text{nc}} = \tfrac{1}{2}V_0^2\frac{dC}{dx} + V_0\frac{dQ_{\text{battery}}}{dx} = \tfrac{1}{2}V_0^2\frac{dC}{dx} - V_0\frac{dQ_{\text{cap}}}{dx} = \tfrac{1}{2}V_0^2\frac{dC}{dx} - V_0^2\frac{dC}{dx} = -\tfrac{1}{2}V_0^2\frac{dC}{dx}$$

$$= -\tfrac{1}{2}V_0^2\varepsilon_0\frac{\ell^2}{d}\left[\frac{(K-1)}{\ell}\right] = -\frac{V_0^2\varepsilon_0\ell}{2d}(K-1)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Note that this force is in the opposite direction of *dx*, and so is to the right. Since this force is being applied to keep the dielectric from accelerating, there must be a force of equal magnitude to the left pulling on the dielectric. This force is due to the attraction of the charged plates and the induced charge on the dielectric. The magnitude and direction of this attractive force are $\boxed{\frac{V_0^2 \varepsilon_0 \ell}{2d}(K-1),\ \text{left}}$.

64. (*a*) We consider the cylinder as two cylindrical capacitors in parallel. The two "negative plates" are the (connected) halves of the inner cylinder (half of which is in contact with liquid, and half of which is in contact with vapor). The two "positive plates" are the (connected) halves of the outer cylinder (half of which is in contact with liquid, and half of which is in contact with vapor). Schematically, it is like Figure 24-30 in Problem 59. The capacitance of a cylindrical capacitor is given in Example 24-2.

$$C = C_{\text{liq}} + C_{\text{V}} = \frac{2\pi\varepsilon_0 K_{\text{liq}} h}{\ln\left(R_{\text{a}}/R_{\text{b}}\right)} + \frac{2\pi\varepsilon_0 K_{\text{V}}\left(\ell - h\right)}{\ln\left(R_{\text{a}}/R_{\text{b}}\right)} = \frac{2\pi\varepsilon_0 \ell}{\ln\left(R_{\text{a}}/R_{\text{b}}\right)}\left[\left(K_{\text{liq}} - K_{\text{V}}\right)\frac{h}{\ell} + K_{\text{V}}\right] = C \quad \rightarrow$$

$$\frac{h}{\ell} = \boxed{\frac{1}{\left(K_{\text{liq}} - K_{\text{V}}\right)}\left[\frac{C\ln\left(R_{\text{a}}/R_{\text{b}}\right)}{2\pi\varepsilon_0 \ell} - K_{\text{V}}\right]}$$

(*b*) For the full tank, $\frac{h}{\ell} = 1,$ and for the empty tank, $\frac{h}{\ell} = 0.$

Full: $$C = \frac{2\pi\varepsilon_0 \ell}{\ln\left(R_{\text{a}}/R_{\text{b}}\right)}\left[\left(K_{\text{liq}} - K_{\text{V}}\right)\frac{h}{\ell} + K_{\text{V}}\right] = \frac{2\pi\varepsilon_0 \ell K_{\text{liq}}}{\ln\left(R_{\text{a}}/R_{\text{b}}\right)}$$

$$= \frac{2\pi\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(2.0\ \text{m}\right)\left(1.4\right)}{\ln\left(5.0\ \text{mm}/4.5\ \text{mm}\right)} = \boxed{1.5\times10^{-9}\ \text{F}}$$

Empty: $$C = \frac{2\pi\varepsilon_0 \ell}{\ln\left(R_{\text{a}}/R_{\text{b}}\right)}\left[\left(K_{\text{liq}} - K_{\text{V}}\right)\frac{h}{\ell} + K_{\text{V}}\right] = \frac{2\pi\varepsilon_0 \ell K_{\text{V}}}{\ln\left(R_{\text{a}}/R_{\text{b}}\right)}$$

$$= \frac{2\pi\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(2.0\ \text{m}\right)\left(1.0\right)}{\ln\left(5.0\ \text{mm}/4.5\ \text{mm}\right)} = \boxed{1.1\times10^{-9}\ \text{F}}$$

65. Consider the dielectric as having a layer of equal and opposite charges at each side of the dielectric. Then the geometry is like three capacitors in series. One air gap is taken to be $d_1,$ and then the other air gap is $d - d_1 - \ell.$

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} = \frac{d_1}{\varepsilon_0 A} + \frac{\ell}{K\varepsilon_0 A} + \frac{d - d_1 - \ell}{\varepsilon_0 A} = \frac{1}{\varepsilon_0 A}\left(\left[\frac{\ell}{K} + \left(d - \ell\right)\right]\right) \quad \rightarrow$$

$$C = \frac{\varepsilon_0 A}{\left[\frac{\ell}{K} + \left(d - \ell\right)\right]} = \frac{\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(2.50\times10^{-2}\ \text{m}^2\right)}{\left[\frac{1.00\times10^{-3}\ \text{m}}{3.50} + \left(1.00\times10^{-3}\ \text{m}\right)\right]} = \boxed{1.72\times10^{-10}\ \text{F}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

66. By leaving the battery connected, the voltage will not change when the dielectric is inserted, but the amount of charge will change. That will also change the electric field.

(*a*) Use Eq. 24-2 to find the capacitance.

$$C_0 = \varepsilon_0 \frac{A}{d} = \left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(\frac{2.50\times10^{-2}\ \text{m}^2}{2.00\times10^{-3}\ \text{m}}\right) = 1.106\times10^{-10}\ \text{F} \approx \boxed{1.11\times10^{-10}\ \text{F}}$$

(*b*) Use Eq. 24-1 to find the initial charge on each plate.

$$Q_0 = C_0 V = \left(1.106\times10^{-10}\ \text{F}\right)\left(150\ \text{V}\right) = 1.659\times10^{-8}\ \text{C} \approx \boxed{1.66\times10^{-8}\ \text{C}}$$

In Example 24-12, the charge was constant, so it was simple to calculate the induced charge and then the electric fields from those charges. But now the voltage is constant, and so we calculate the fields first, and then calculate the charges. So we are solving the problem parts in a different order.

(*d*) We follow the same process as in part (*f*) of Example 24-12.

$$V = E_0\left(d-\ell\right) + E_{\text{D}}\ell = E_0\left(d-\ell\right) + \frac{E_0}{K}\ell \quad \rightarrow$$

$$E_0 = \frac{V}{d-\ell+\dfrac{\ell}{K}} = \frac{\left(150\ \text{V}\right)}{\left(2.00\times10^{-3}\ \text{m}\right)-\left(1.00\times10^{-3}\ \text{m}\right)+\dfrac{\left(1.00\times10^{-3}\ \text{m}\right)}{\left(3.50\right)}} = 1.167\times10^{5}\ \text{V/m}$$

$$\approx \boxed{1.17\times10^{5}\ \text{V/m}}$$

(*e*) $E_{\text{D}} = \dfrac{E_0}{K} = \dfrac{1.167\times10^{5}\ \text{V/m}}{3.50} = 3.333\times10^{4}\ \text{V/m} \approx \boxed{3.33\times10^{4}\ \text{V/m}}$

(*h*) $E_0 = \dfrac{\sigma}{\varepsilon_0} = \dfrac{Q}{A\varepsilon_0} \quad \rightarrow$

$$Q = EA\varepsilon_0 = \left(1.167\times10^{5}\ \text{V/m}\right)\left(0.0250\ \text{m}^2\right)\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right) = 2.582\times10^{-8}\ \text{C}$$

$$\approx \boxed{2.58\times10^{-8}\ \text{C}}$$

(*c*) $Q_{\text{ind}} = Q\left(1-\dfrac{1}{K}\right) = \left(2.582\times10^{-8}\ \text{C}\right)\left(1-\dfrac{1}{3.50}\right) = \boxed{1.84\times10^{-8}\ \text{C}}$

(*f*) Because the battery voltage does not change, the potential difference between the plates is unchanged when the dielectric is inserted, and so is $V = \boxed{150\ \text{V}}$.

(*g*) $C = \dfrac{Q}{V} = \dfrac{2.582\times10^{-8}\ \text{C}}{150\ \text{V}} = \boxed{1.72\times10^{-10}\ \text{pF}}$

Notice that the capacitance is the same as in Example 24-12. Since the capacitance is a constant (function of geometry and material, not charge and voltage), it should be the same value.

67. The capacitance will be given by $C = Q/V$. When a charge Q is placed on one plate and a charge $-Q$ is placed on the other plate, an electric field will be set up between the two plates. The electric field in the air-filled region is just the electric field between two charged plates, $E_0 = \dfrac{\sigma}{\varepsilon_0} = \dfrac{Q}{A\varepsilon_0}$. The electric field in the dielectric is equal to the electric field in the air,

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

divided by the dielectric constant: $E_D = \dfrac{E_0}{K} = \dfrac{Q}{KA\varepsilon_0}$.

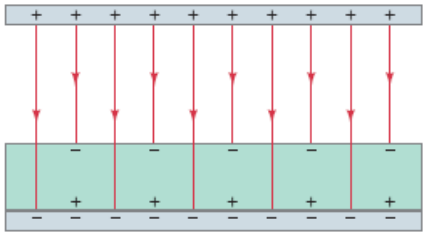
The voltage drop between the two plates is obtained by integrating the electric field between the two plates. One plate is set at the origin with the dielectric touching this plate. The dielectric ends at $x = \ell$. The rest of the distance to $x = d$ is then air filled.

$$V = -\int_0^d \vec{\mathbf{E}} \cdot d\vec{\mathbf{x}} = \int_0^\ell \frac{Q dx}{KA\varepsilon_0} + \int_\ell^d \frac{Q dx}{A\varepsilon_0} = \frac{Q}{A\varepsilon_0}\left(\frac{\ell}{K} + (d-\ell)\right)$$

The capacitance is the ratio of the voltage to the charge.

$$C = \frac{Q}{V} = \frac{Q}{\dfrac{Q}{A\varepsilon_0}\left(\dfrac{\ell}{K} + (d-\ell)\right)} = \boxed{\frac{\varepsilon_0 A}{d - \ell + \dfrac{\ell}{K}}}$$

68. Find the energy in each region from the energy density and the volume. The energy density in the "gap" is given by $u_{\text{gap}} = \frac{1}{2}\varepsilon_0 E_{\text{gap}}^2$, and the energy density in the dielectric is given by $u_{\text{D}} = \frac{1}{2}\varepsilon_D E_{\text{D}}^2$



$= \frac{1}{2}K\varepsilon_0\left(\dfrac{E_{\text{gap}}}{K}\right)^2 = \frac{1}{2}\varepsilon_0 \dfrac{E_{\text{gap}}^2}{K}$, where Eq. 24-10 is used.

$$\frac{U_{\text{D}}}{U_{\text{total}}} = \frac{U_{\text{D}}}{U_{\text{gap}} + U_{\text{D}}} = \frac{u_{\text{D}}\text{Vol}_{\text{D}}}{u_{\text{gap}}\text{Vol}_{\text{gap}} + u_{\text{D}}\text{Vol}_{\text{D}}} = \frac{\frac{1}{2}\varepsilon_0 \dfrac{E_{\text{gap}}^2}{K} A\ell}{\frac{1}{2}\varepsilon_0 E_{\text{gap}}^2 A(d-\ell) + \frac{1}{2}\varepsilon_0 \dfrac{E_{\text{gap}}^2}{K} A\ell}$$

$$= \frac{\dfrac{\ell}{K}}{(d-\ell) + \dfrac{\ell}{K}} = \frac{\ell}{(d-\ell)K + \ell} = \frac{(1.00\,\text{mm})}{(1.00\,\text{mm})(3.50) + (1.00\,\text{mm})} = \boxed{0.222}$$

69. There are two uniform electric fields – one in the air, and one in the gap. They are related by Eq. 24-10. In each region, the potential difference is the field times the distance in the direction of the field over which the field exists.

$$V = E_{\text{air}} d_{\text{air}} + E_{\text{glass}} d_{\text{glass}} = E_{\text{air}} d_{\text{air}} + \frac{E_{\text{air}}}{K_{\text{glass}}} d_{\text{glass}} \quad \rightarrow$$

$$E_{\text{air}} = V \frac{K_{\text{glass}}}{d_{\text{air}} K_{\text{glass}} + d_{\text{glass}}}$$

$$= (90.0\,\text{V}) \frac{5.80}{(3.00\times10^{-3}\,\text{m})(5.80) + (2.00\times10^{-3}\,\text{m})}$$

$$= \boxed{2.69\times10^4\ \text{V/m}}$$

$$E_{\text{glass}} = \frac{E_{\text{air}}}{K_{\text{glass}}} = \frac{2.69\times10^4\ \text{V/m}}{5.80} = \boxed{4.64\times10^3\ \text{V/m}}$$

The charge on the plates can be calculated from the field at the plate, using Eq. 22-5. Use Eq. 24-11b to calculate the charge on the dielectric.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E_{\text{air}} = \frac{\sigma_{\text{plate}}}{\varepsilon_0} = \frac{Q_{\text{plate}}}{\varepsilon_0 A} \quad \rightarrow$$

$$Q_{\text{plate}} = E_{\text{air}}\varepsilon_0 A = \left(2.69\times10^4\ \text{V/m}\right)\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(1.45\,\text{m}^2\right) = \boxed{3.45\times10^{-7}\,\text{C}}$$

$$Q_{\text{ind}} = Q\left(1-\frac{1}{K}\right) = \left(3.45\times10^{-7}\,\text{C}\right)\left(1-\frac{1}{5.80}\right) = \boxed{2.86\times10^{-7}\,\text{C}}$$

70. (*a*) The capacitance of a single isolated conducting sphere is given after example 24-3.

$$C = 4\pi\varepsilon_0 r \quad \rightarrow$$

$$\frac{C}{r} = 4\pi\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right) = \left(1.11\times10^{-10}\,\frac{\text{F}}{\text{m}}\right)\left(\frac{1\,\text{m}}{100\,\text{cm}}\right)\left(\frac{10^{12}\,\text{pF}}{1\,\text{F}}\right) = 1.11\,\text{pF/cm}$$

And so $C = (1.11\,\text{pF/cm})\,r \quad \rightarrow \quad \boxed{C\,(\text{pF}) \approx r\,(\text{cm})}$.

(*b*) We assume that the human body is a sphere of radius 100 cm. Thus the rule $C\,(\text{pF}) \approx r\,(\text{cm})$ says that the capacitance of the human body is about $\boxed{100\,\text{pF}}$.

(*c*) A 0.5-cm spark would require a potential difference of about 15,000 V. Use Eq. 24-1.

$$Q = CV = (100\,\text{pF})(15{,}000\,\text{V}) = \boxed{1.5\mu\text{C}}$$

71. Use Eq. 24-5 to find the capacitance.

$$U = \tfrac{1}{2}CV^2 \quad \rightarrow \quad C = \frac{2U}{V^2} = \frac{2(1200\,\text{J})}{(7500\,\text{V})^2} = \boxed{4.3\times10^{-5}\,\text{F}}$$

72. (*a*) We approximate the configuration as a parallel-plate capacitor, and so use Eq. 24-2 to calculate the capacitance.

$$C = \varepsilon_0\frac{A}{d} = \varepsilon_0\frac{\pi r^2}{d} = \left(8.85\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\frac{\pi\left[(4.5\,\text{in})(0.0254\,\text{m/in})\right]^2}{0.050\,\text{m}} = 7.265\times10^{-12}\,\text{F}$$

$$\approx \boxed{7\times10^{-12}\,\text{F}}$$

(*b*) Use Eq. 24-1.

$$Q = CV = \left(7.265\times10^{-12}\,\text{F}\right)(9\,\text{V}) = 6.539\times10^{-11}\,\text{C} \approx \boxed{7\times10^{-11}\,\text{C}}$$

(*c*) The electric field is uniform, and is the voltage divided by the plate separation.

$$E = \frac{V}{d} = \frac{9\,\text{V}}{0.050\,\text{m}} = 180\,\text{V/m} \approx \boxed{200\,\text{V/m}}$$

(*d*) The work done by the battery to charge the plates is equal to the energy stored by the capacitor. Use Eq. 24-5.

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\left(7.265\times10^{-12}\,\text{F}\right)(9\,\text{V})^2 = 2.942\times10^{-10}\,\text{J} \approx \boxed{3\times10^{-10}\,\text{J}}$$

(*e*) The electric field will stay the same, because the voltage will stay the same (since the capacitor is still connected to the battery) and the plate separation will stay the same. The capacitance changes, and so the charge changes (by Eq. 24-1), and so the work done by the battery changes (by Eq. 24-5).

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

73. Since the capacitor is disconnected from the battery, the charge on it cannot change. The capacitance of the capacitor is increased by a factor of *K*, the dielectric constant.

$$Q = C_{\text{initial}}V_{\text{initial}} = C_{\text{final}}V_{\text{final}} \quad \rightarrow \quad V_{\text{final}} = V_{\text{initial}}\frac{C_{\text{initial}}}{C_{\text{final}}} = V_{\text{initial}}\frac{C_{\text{initial}}}{KC_{\text{initial}}} = (34.0\,\text{V})\frac{1}{2.2} = \boxed{15\,\text{V}}$$

74. The energy is given by Eq. 24-5. Calculate the energy difference for the two different amounts of charge, and then solve for the difference.

$$U = \tfrac{1}{2}\frac{Q^2}{C} \quad \rightarrow \quad \Delta U = \tfrac{1}{2}\frac{(Q+\Delta Q)^2}{C} - \tfrac{1}{2}\frac{Q^2}{C} = \frac{1}{2C}\left[(Q+\Delta Q)^2 - Q^2\right] = \frac{\Delta Q}{2C}\left[2Q + \Delta Q\right] \quad \rightarrow$$

$$Q = \frac{C\Delta U}{\Delta Q} - \tfrac{1}{2}\Delta Q = \frac{(17.0\times10^{-6}\,\text{F})(18.5\,\text{J})}{(13.0\times10^{-3}\,\text{C})} - \tfrac{1}{2}(13.0\times10^{-3}\,\text{C}) = \boxed{17.7\times10^{-3}\,\text{C}} = 17.7\,\text{mC}$$

75. The energy in the capacitor, given by Eq. 24-5, is the heat energy absorbed by the water, given by Eq. 19-2.

$$U = Q_{\text{heat}} \quad \rightarrow \quad \tfrac{1}{2}CV^2 = mc\Delta T \quad \rightarrow$$

$$V = \sqrt{\frac{2mc\Delta T}{C}} = \sqrt{\frac{2(3.5\,\text{kg})\left(4186\,\frac{\text{J}}{\text{kg}\bullet^\circ\text{C}}\right)(95^\circ\text{C} - 22^\circ\text{C})}{3.0\,\text{F}}} = 844\,\text{V} \approx \boxed{840\,\text{V}}$$

76. (*a*) The capacitance per unit length of a cylindrical capacitor with no dielectric is derived in Example 24-2, as $\frac{C}{\ell} = \frac{2\pi\varepsilon_0}{\ln(R_{\text{outside}}/R_{\text{inside}})}$. The addition of a dielectric increases the capacitance by a factor of *K*.

$$\frac{C}{\ell} = \boxed{\frac{2\pi\varepsilon_0 K}{\ln(R_{\text{outside}}/R_{\text{inside}})}}$$

(*b*) $$\frac{C}{\ell} = \frac{2\pi\varepsilon_0 K}{\ln(R_{\text{outside}}/R_{\text{inside}})} = \frac{2\pi(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)2.6}{\ln(9.0\,\text{mm}/2.5\,\text{mm})} = \boxed{1.1\times10^{-10}\,\text{F/m}}$$

77. The potential can be found from the field and the plate separation. Then the capacitance is found from Eq. 24-1, and the area from Eq. 24-8.

$$E = \frac{V}{d} \;;\; Q = CV = CEd \quad \rightarrow$$

$$C = \frac{Q}{Ed} = \frac{(0.675\times10^{-6}\,\text{C})}{(9.21\times10^4\,\text{V/m})(1.95\times10^{-3}\,\text{m})} = 3.758\times10^{-9}\,\text{F} \approx \boxed{3.76\times10^{-9}\,\text{F}}$$

$$C = K\varepsilon_0\frac{A}{d} \quad \rightarrow \quad A = \frac{Cd}{K\varepsilon_0} = \frac{(3.758\times10^{-9}\,\text{F})(1.95\times10^{-3}\,\text{m})}{(3.75)(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)} = \boxed{0.221\,\text{m}^2}$$

78. (*a*) If *N* electrons flow onto the plate, the charge on the top plate is $-Ne$, and the positive charge associated with the capacitor is $Q = Ne$. Since $Q = CV$, we have $Ne = CV \quad \rightarrow \quad \boxed{V = Ne/C}$, showing that *V* is proportional to *N*.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Given $\Delta V = 1\,\text{mV}$ and we want $\Delta N = 1$, solve for the capacitance.

$$V = \frac{Ne}{C} \quad \rightarrow \quad \Delta V = \frac{e\Delta N}{C} \quad \rightarrow$$

$$C = e\frac{\Delta N}{\Delta V} = \left(1.60\times10^{-19}\,\text{C}\right)\frac{1}{1\times10^{-3}\,\text{V}} = 1.60\times10^{-16}\,\text{F} \approx \boxed{2\times10^{-16}\,\text{F}}$$

(*c*) Use Eq. 24-8.

$$C = \varepsilon_0 K\frac{A}{d} = \varepsilon_0 K\frac{\ell^2}{d} \quad \rightarrow$$

$$\ell = \sqrt{\frac{Cd}{\varepsilon_0 K}} = \sqrt{\frac{\left(1.60\times10^{-16}\,\text{F}\right)\left(100\times10^{-9}\,\text{m}\right)}{\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)(3)}} = 7.76\times10^{-7}\,\text{m}\left(\frac{10^6\,\mu\text{m}}{1\,\text{m}}\right) = \boxed{0.8\,\mu\text{m}}$$

79. The relative change in energy can be obtained by inserting Eq. 24-8 into Eq. 24-5.

$$\frac{U}{U_0} = \frac{\dfrac{Q^2}{2C}}{\dfrac{Q^2}{2C_0}} = \frac{C_0}{C} = \frac{\dfrac{A\varepsilon_0}{d}}{\dfrac{KA\varepsilon_0}{\left(\frac{1}{2}d\right)}} = \boxed{\frac{1}{2K}}$$

The dielectric is attracted to the capacitor. As such, the dielectric will gain kinetic energy as it enters the capacitor. An external force is necessary to stop the dielectric. The negative work done by this force results in the decrease in energy within the capacitor.

Since the charge remains constant, and the magnitude of the electric field depends on the charge, and not the separation distance, the electric field will not be affected by the change in distance between the plates. The electric field between the plates will be reduced by the dielectric constant, as given in Eq. 24-10.

$$\frac{E}{E_0} = \frac{E_0/K}{E_0} = \boxed{\frac{1}{K}}$$

80. (*a*) Use Eq. 24-2.

$$C = \frac{\varepsilon_0 A}{d} = \frac{\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(120\times10^6\,\text{m}^2\right)}{\left(1500\,\text{m}\right)} = 7.08\times10^{-7}\,\text{F} \approx \boxed{7.1\times10^{-7}\,\text{F}}$$

(*b*) Use Eq. 24-1.

$$Q = CV = \left(7.08\times10^{-7}\,\text{F}\right)\left(3.5\times10^7\,\text{V}\right) = 24.78\,\text{C} \approx \boxed{25\,\text{C}}$$

(*c*) Use Eq. 24-5.

$$U = \tfrac{1}{2}QV = \tfrac{1}{2}\left(24.78\,\text{C}\right)\left(3.5\times10^7\,\text{V}\right) = 4.337\times10^8\,\text{J} \approx \boxed{4.3\times10^8\,\text{J}}$$

81. We treat this as *N* capacitors in parallel, so that the total capacitance is *N* times the capacitance of a single capacitor. The maximum voltage and dielectric strength are used to find the plate separation of a single capacitor.

$$d = \frac{V}{E_S} = \frac{100\,\text{V}}{30\times10^6\,\text{V/m}} = 3.33\times10^{-6}\,\text{m} \;;\; N = \frac{\ell}{d} = \frac{6.0\times10^{-3}\,\text{m}}{3.33\times10^{-6}\,\text{m}} = 1800$$

$$C_{\text{eq}} = NC = N\varepsilon_0 K\frac{A}{d} \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$K = \frac{C_{\text{eq}}d}{N\varepsilon_0 A} = \frac{\left(1.0\times10^{-6}\,\text{F}\right)\left(3.33\times10^{-6}\,\text{m}\right)}{1800\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(12.0\times10^{-3}\,\text{m}\right)\left(14.0\times10^{-3}\,\text{m}\right)} = 1.244 \approx \boxed{1.2}$$

82. The total charge doesn't change when the second capacitor is connected, since the two-capacitor combination is not connected to a source of charge. The final voltage across the two capacitors must be the same. Use Eq. 24-1.

$$Q_0 = C_1V_0 = Q_1 + Q_2 = C_1V_1 + C_2V_2 = C_1V_1 + C_2V_1$$

$$C_2 = C_1\frac{(V_0 - V_1)}{V_1} = (3.5\mu\text{F})\left(\frac{12.4\,\text{V} - 5.9\,\text{V}}{5.9\,\text{V}}\right) = 3.856\mu\text{F} \approx \boxed{3.9\mu\text{F}}$$

83. (*a*) Use Eq. 24-5 to calculate the stored energy.

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\left(8.0\times10^{-8}\,\text{F}\right)\left(2.5\times10^{4}\,\text{V}\right)^2 = \boxed{25\,\text{J}}$$

(*b*) The power is the energy converted per unit time.

$$P = \frac{\text{Energy}}{\text{time}} = \frac{0.15(25\,\text{J})}{4.0\times10^{-6}\,\text{s}} = 9.38\times10^{5}\,\text{W} \approx \boxed{940\,\text{kW}}$$

84. The pressure is the force per unit area on a face of the dielectric. The force is related to the potential energy stored in the capacitor by Eq. 8-7, $F = -\dfrac{dU}{dx}$, where x is the separation of the capacitor plates.

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\left(K\varepsilon_0\frac{A}{x}\right)V^2 \;\rightarrow\; F = -\frac{dU}{dx} = \frac{K\varepsilon_0 AV^2}{2x^2}\;;\; P = \frac{F}{A} = \frac{K\varepsilon_0 V^2}{2x^2} \;\rightarrow$$

$$V = \sqrt{\frac{2x^2P}{K\varepsilon_0}} = \sqrt{\frac{2\left(1.0\times10^{-4}\,\text{m}\right)^2\left(40.0\,\text{Pa}\right)}{(3.1)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}} = \boxed{170\,\text{V}}$$

85. (*a*) From the diagram, we see that one group of 4 plates is connected together, and the other group of 4 plates is connected together. This common grouping shows that the capacitors are connected in parallel.

(*b*) Since they are connected in parallel, the equivalent capacitance is the sum of the individual capacitances. The variable area will change the equivalent capacitance.

$$C_{\text{eq}} = 7C = 7\varepsilon_0\frac{A}{d}$$

$$C_{\text{min}} = 7\varepsilon_0\frac{A_{\text{min}}}{d} = 7\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\bullet\text{m}^2\right)\frac{\left(2.0\times10^{-4}\,\text{m}^2\right)}{\left(1.6\times10^{-3}\,\text{m}\right)} = 7.7\times10^{-12}\,\text{F}$$

$$C_{\text{max}} = 7\varepsilon_0\frac{A_{\text{max}}}{d} = 7\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\bullet\text{m}^2\right)\frac{\left(9.0\times10^{-4}\,\text{m}^2\right)}{\left(1.6\times10^{-3}\,\text{m}\right)} = 3.5\times10^{-11}\,\text{F}$$

And so the range is $\boxed{\text{from } 7.7\,\text{pF to } 35\,\text{pF}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

86. (*a*) Since the capacitor is charged and then disconnected from the power supply, the charge is constant. Use Eq. 24-1 to find the new voltage.

$$Q = CV = \text{constant} \;\rightarrow\; C_1V_1 = C_2V_2 \;\rightarrow\; V_2 = V_1\frac{C_1}{C_2} = (7500\,\text{V})\frac{8.0\,\text{pF}}{1.0\,\text{pF}} = \boxed{6.0\times10^4\,\text{V}}$$

(*b*) In using this as a high voltage power supply, once it discharges, the voltage drops, and it needs to be recharged. So it is not a constant source of high voltage. You would also have to be sure it was designed to not have breakdown of the capacitor material when the voltage gets so high. Another disadvantage is that it has only a small amount of energy stored: $U = \frac{1}{2}CV^2$ $= \frac{1}{2}\left(1.0\times10^{-12}\,\text{C}\right)\left(6.0\times10^4\,\text{V}\right)^2 = 1.8\times10^{-3}\,\text{J}$, and so could actually only supply a small amount of power unless the discharge time was extremely short.

87. Since the two capacitors are in series, they will both have the same charge on them.

$$Q_1 = Q_2 = Q_{\text{series}} \;;\; \frac{1}{C_{\text{series}}} = \frac{V}{Q_{\text{series}}} = \frac{1}{C_1} + \frac{1}{C_2} \;\rightarrow$$

$$C_2 = \frac{Q_{\text{series}}C_1}{C_1V - Q_{\text{series}}} = \frac{\left(125\times10^{-12}\,\text{C}\right)\left(175\times10^{-12}\,\text{F}\right)}{\left(175\times10^{-12}\,\text{F}\right)\left(25.0\,\text{V}\right) - \left(125\times10^{-12}\,\text{C}\right)} = \boxed{5.15\times10^{-12}\,\text{F}}$$

88. (*a*) The charge can be determined from Eqs. 24-1 and 24-2.

$$Q = CV = \varepsilon_0\frac{A}{d}V = \left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\frac{\left(2.0\times10^{-4}\,\text{m}^2\right)}{\left(5.0\times10^{-4}\,\text{m}\right)}\left(12\,\text{V}\right) = 4.248\times10^{-11}\,\text{C}$$

$$\approx \boxed{4.2\times10^{-11}\,\text{C}}$$

(*b*) Since the battery is disconnected, no charge can flow to or from the plates. Thus the charge is constant.

$$Q = \boxed{4.2\times10^{-11}\,\text{C}}$$

(*c*) The capacitance has changed and the charge has stayed constant, and so the voltage has changed.

$$Q = CV = \text{constant} \;\rightarrow\; C_1V_1 = C_0V_0 \;\rightarrow\; \varepsilon_0\frac{A}{d_1}V_1 = \varepsilon_0\frac{A}{d_0}V_0 \;\rightarrow$$

$$V_1 = \frac{d_1}{d_0}V_0 = \frac{0.75\,\text{mm}}{0.50\,\text{mm}}\left(12\,\text{V}\right) = \boxed{18\,\text{V}}$$

(*d*) The work is the change in stored energy.

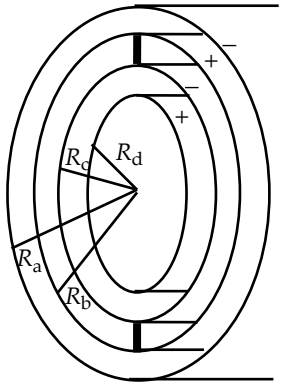
$$W = \Delta U = \tfrac{1}{2}QV_1 - \tfrac{1}{2}QV_0 = \tfrac{1}{2}Q\left(V_1 - V_0\right) = \tfrac{1}{2}\left(4.248\times10^{-11}\,\text{C}\right)\left(6.0\,\text{V}\right) = \boxed{1.3\times10^{-10}\,\text{J}}$$

89. The first capacitor is charged, and so has a certain amount of charge on its plates. Then, when the switch is moved, the capacitors are not connected to a source of charge, and so the final charge is equal to the initial charge. Initially treat capacitors C_2 and C_3 as their equivalent capacitance, $C_{23} = \dfrac{C_2C_3}{C_2 + C_3} = \dfrac{\left(2.0\mu\text{F}\right)\left(2.4\mu\text{F}\right)}{4.4\mu\text{F}} = 1.091\mu\text{F}$. The final voltage across C_1 and C_{23} must be the same. The charge on C_2 and C_3 must be the same. Use Eq. 24-1.

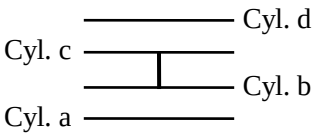
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$Q_0 = C_1V_0 = Q_1 + Q_{23} = C_1V_1 + C_{23}V_{23} = C_1V_1 + C_{23}V_1 \quad \rightarrow$$

$$V_1 = \frac{C_1}{C_1 + C_{23}}V_0 = \frac{1.0\,\mu\text{F}}{1.0\,\mu\text{F} + 1.091\,\mu\text{F}}(24\,\text{V}) = 11.48\,\text{V} = V_1 = V_{23}$$



$$Q_1 = C_1V_1 = (1.0\,\mu\text{F})(11.48\,\text{V}) = 11.48\,\mu\text{C}$$



$$Q_{23} = C_{23}V_{23} = (1.091\,\mu\text{F})(11.48\,\text{V}) = 12.52\,\mu\text{C} = Q_2 = Q_3$$

$$V_2 = \frac{Q_2}{C_2} = \frac{12.52\,\mu\text{C}}{2.0\,\mu\text{F}} = 6.26\,\text{V} \;;\; V_3 = \frac{Q_3}{C_3} = \frac{12.52\,\mu\text{C}}{2.4\,\mu\text{F}} = 5.22\,\text{V}$$

To summarize: $\boxed{Q_1 = 11\,\mu\text{C}\,,\, V_1 = 11\,\text{V} \;;\; Q_2 = 13\,\mu\text{C}\,,\, V_2 = 6.3\,\text{V} \;;\; Q_3 = 13\,\mu\text{C}\,,\, V_3 = 5.2\,\text{V}}$

90. The metal conducting strips connecting cylinders b and c mean that b and c are at the same potential. Due to the positive charge on the inner cylinder and the negative charge on the outer cylinder, cylinders b and c will polarize according to the first diagram, with negative charge on cylinder c, and positive charge on cylinder b. This is then two capacitors in series, as illustrated in the second diagram. The capacitance per unit length of a cylindrical capacitor is derived in Example 24-2.

$$C_1 = \frac{2\pi\varepsilon_0\ell}{\ln(R_a/R_b)} \;;\; C_2 = \frac{2\pi\varepsilon_0\ell}{\ln(R_c/R_d)} \;;\; \frac{1}{C_{\text{net}}} = \frac{1}{C_1} + \frac{1}{C_2} \quad \rightarrow$$

$$C_{\text{net}} = \frac{C_1C_2}{C_1 + C_2} = \frac{\left[\dfrac{2\pi\varepsilon_0\ell}{\ln(R_a/R_b)}\right]\left[\dfrac{2\pi\varepsilon_0\ell}{\ln(R_c/R_d)}\right]}{\dfrac{2\pi\varepsilon_0\ell}{\ln(R_a/R_b)} + \dfrac{2\pi\varepsilon_0\ell}{\ln(R_c/R_d)}}$$

$$= \frac{2\pi\varepsilon_0\ell}{\ln(R_c/R_d) + \ln(R_a/R_b)} = \frac{2\pi\varepsilon_0\ell}{\ln(R_aR_c/R_bR_d)} \quad \rightarrow$$

$$\frac{C}{\ell} = \boxed{\frac{2\pi\varepsilon_0}{\ln(R_aR_c/R_bR_d)}}$$

91. The force acting on one plate by the other plate is equal to the electric field produced by one charged plate multiplied by the charge on the second plate.

$$F = EQ = \left(\frac{Q}{2A\varepsilon_0}\right)Q = \frac{Q^2}{2A\varepsilon_0}$$

The force is attractive since the plates are oppositely charged. Since the force is constant, the work done in pulling the two plates apart by a distance x is just the force times distance.

$$W = Fx = \boxed{\frac{Q^2x}{2A\varepsilon_0}}$$

The change in energy stored between the plates is obtained using Eq. 24-5.

$$W = \Delta U = \frac{Q^2}{2}\left(\frac{1}{C_2} - \frac{1}{C_1}\right) = \frac{Q^2}{2}\left(\frac{2x}{\varepsilon_0 A} - \frac{x}{\varepsilon_0 A}\right) = \boxed{\frac{Q^2x}{2\varepsilon_0 A}}$$

The work done in pulling the plates apart is equal to the increase in energy between the plates.

92. Since the other values in this problem manifestly have 2 significant figures, we assume that the capacitance also has 2 significant figures.

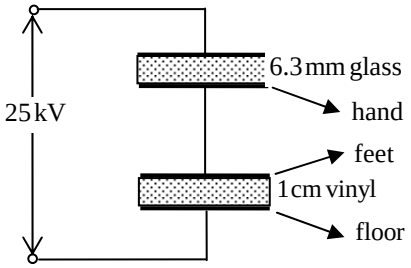
(*a*) The number of electrons is found from the charge on the capacitor.

$$Q = CV = Ne \quad \rightarrow \quad N = \frac{CV}{e} = \frac{\left(30\times10^{-15}\,\text{F}\right)\left(1.5\,\text{V}\right)}{1.60\times10^{-19}\,\text{C}} = \boxed{2.8\times10^{5}\,e\text{'s}}$$

(*b*) The thickness is determined from the dielectric strength.

$$E_{\max} = \frac{V}{d_{\min}} \quad \rightarrow \quad d_{\min} = \frac{V}{E_{\max}} = \frac{1.5\,\text{V}}{1.0\times10^{9}\,\text{V/m}} = \boxed{1.5\times10^{-9}\,\text{m}}$$

(*c*) The area is found from Eq. 24-8.



$$C = K\varepsilon_0\frac{A}{d} \quad \rightarrow \quad A = \frac{Cd}{K\varepsilon_0} = \frac{\left(30\times10^{-15}\,\text{F}\right)\left(1.5\times10^{-9}\,\text{m}\right)}{25\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)} = \boxed{2.0\times10^{-13}\,\text{m}}$$

93. Use Eq. 24-2 for the capacitance.

$$C = \frac{\varepsilon_0 A}{d} \quad \rightarrow \quad d = \frac{\varepsilon_0 A}{C} = \frac{\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(1.0\times10^{-4}\,\text{m}^2\right)}{\left(1\text{F}\right)} = \boxed{9\times10^{-16}\,\text{m}}$$

No, this is not practically achievable. The gap would have to be smaller than the radius of a proton.

94. See the schematic diagram for the arrangement. The two "capacitors" are in series, and so have the same charge. Thus their voltages, which must total 25kV, will be inversely proportional to their capacitances. Let C_1 be the glass-filled capacitor, and C_2 be the vinyl capacitor. The area of the foot is approximately twice the area of the hand, and since there are two feet on the floor and only one hand on the screen, the area ratio is $\frac{A_{\text{foot}}}{A_{\text{hand}}} = \frac{4}{1}$.

$$Q = C_1V_1 = C_2V_2 \quad \rightarrow \quad V_1 = V_2\frac{C_2}{C_1}$$

$$C_1 = \frac{\varepsilon_0 K_{\text{glass}} A_{\text{hand}}}{d_{\text{glass}}} \;;\; C_2 = \frac{\varepsilon_0 K_{\text{vinyl}} A_{\text{foot}}}{d_{\text{vinyl}}}$$

$$\frac{C_2}{C_1} = \frac{\dfrac{\varepsilon_0 K_{\text{vinyl}} A_{\text{foot}}}{d_{\text{vinyl}}}}{\dfrac{\varepsilon_0 K_{\text{glass}} A_{\text{hand}}}{d_{\text{glass}}}} = \frac{K_{\text{vinyl}} A_{\text{foot}} d_{\text{glass}}}{K_{\text{glass}} A_{\text{hand}} d_{\text{vinyl}}} = \frac{(3)(4)(0.63)}{(5)(1)(1.0)} = 1.5$$

$$V = V_1 + V_2 = V_2\frac{C_2}{C_1} + V_2 = 2.5V_2 = 25{,}000\,\text{V} \quad \rightarrow \quad V_2 = \boxed{10{,}000\,\text{V}}$$

95. (*a*) Use Eq. 24-2 to calculate the capacitance.

$$C_0 = \frac{\varepsilon_0 A}{d} = \frac{\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(2.0\,\text{m}^2\right)}{\left(3.0\times10^{-3}\,\text{m}\right)} = \boxed{5.9\times10^{-9}\,\text{F}}$$

Use Eq. 24-1 to calculate the charge.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$Q_0 = C_0V_0 = \left(5.9\times10^{-9}\,\text{F}\right)\left(45\,\text{V}\right) = 2.655\times10^{-7}\,\text{C} \approx \boxed{2.7\times10^{-7}\,\text{C}}$$

The electric field is the potential difference divided by the plate separation.

$$E_0 = \frac{V_0}{d} = \frac{45\,\text{V}}{3.0\times10^{-3}\,\text{m}} = \boxed{15000\,\text{V/m}}$$

Use Eq. 24-5 to calculate the energy stored.

$$U_0 = \tfrac{1}{2}C_0V_0^2 = \tfrac{1}{2}\left(5.9\times10^{-9}\,\text{F}\right)\left(45\,\text{V}\right)^2 = \boxed{6.0\times10^{-6}\,\text{J}}$$

(*b*) Now include the dielectric. The capacitance is multiplied by the dielectric constant.

$$C = KC_0 = 3.2\left(5.9\times10^{-9}\,\text{F}\right) = 1.888\times10^{-8}\,\text{F} \approx \boxed{1.9\times10^{-8}\,\text{F}}$$

The voltage doesn't change. Use Eq. 24-1 to calculate the charge.

$$Q = CV = KC_0V = 3.2\left(5.9\times10^{-9}\,\text{F}\right)\left(45\,\text{V}\right) = 8.496\times10^{-7}\,\text{C} \approx \boxed{8.5\times10^{-7}\,\text{C}}$$

Since the battery is still connected, the voltage is the same as before, and so the electric field doesn't change.

$$E = E_0 = \boxed{15000\,\text{V/m}}$$

Use Eq. 24-5 to calculate the energy stored.

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}KC_0V^2 = \tfrac{1}{2}\left(3.2\right)\left(5.9\times10^{-9}\,\text{F}\right)\left(45\,\text{V}\right)^2 = \boxed{1.9\times10^{-5}\,\text{J}}$$

96. (*a*) For a plane conducting surface, the electric field is given by Eq. 22-5.

$$E = \frac{\sigma}{\varepsilon_0} = \frac{Q}{\varepsilon_0 A} \quad\rightarrow\quad Q_{\max} = E_S\varepsilon_0 A = \left(3\times10^6\,\text{N/C}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(150\times10^{-4}\,\text{m}^2\right)$$

$$= 3.98\times10^{-7}\,\text{C} \approx \boxed{4\times10^{-7}\,\text{C}}$$

(*b*) The capacitance of an isolated sphere is derived in the text, right after Example 24-3.

$$C = 4\pi\varepsilon_0 r = 4\pi\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(1\,\text{m}\right) = 1.11\times10^{-10}\,\text{F} \approx \boxed{1\times10^{-10}\,\text{F}}$$

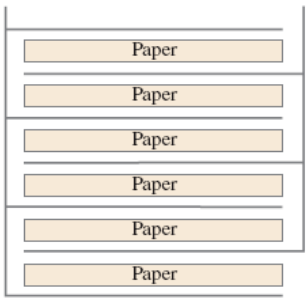
(*c*) Use Eq. 24-1, with the maximum charge from part (a) and the capacitance from part (b).

$$Q = CV \quad\rightarrow\quad V = \frac{Q}{C} = \frac{3.98\times10^{-7}\,\text{C}}{1.11\times10^{-10}\,\text{F}} = 3586\,\text{V} \approx \boxed{4000\,\text{V}}$$

97. (*a*) The initial capacitance is obtained directly from Eq. 24-8.

$$C_0 = \frac{K\varepsilon_0 A}{d} = \frac{3.7\left(8.85\,\text{pF/m}\right)\left(0.21\,\text{m}\right)\left(0.14\,\text{m}\right)}{0.030\times10^{-3}\,\text{m}} = \boxed{32\,\text{nF}}$$

(*b*) Maximum charge will occur when the electric field between the plates is equal to the dielectric strength. The charge will be equal to the capacitance multiplied by the maximum voltage, where the maximum voltage is the electric field times the separation distance of the plates.



$$Q_{\max} = C_0V = C_0Ed = \left(32\,\text{nF}\right)\left(15\times10^6\,\text{V/m}\right)\left(0.030\times10^{-3}\,\text{m}\right)$$

$$= \boxed{14\,\mu\text{C}}$$

(*c*) The sheets of foil would be separated by sheets of paper with alternating sheets connected together on each side. This capacitor would consist of 100 sheets of paper with 101 sheets of foil.

$$t = 101d_{\text{Al}} + 100d_{\text{paper}} = 101\left(0.040\text{ mm}\right) + 100\left(0.030\text{ mm}\right)$$

$$= \boxed{7.0\text{ mm}}$$

(*d*) Since the capacitors are in parallel, each capacitor has the same voltage which is equal to the total voltage. Therefore breakdown will occur when the voltage across a single capacitor provides an electric field across that capacitor equal to the dielectric strength.

$$V_{\max} = E_{\max} d = \left(15 \times 10^6 \text{ V/m}\right)\left(0.030 \times 10^{-3} \text{ m}\right) = \boxed{450 \text{ V}}$$

98. From Eq. 24-2, $C = \dfrac{\varepsilon_0}{d} A$. So if we plot *C* vs. *A*, we should get a straight line with a slope of $\dfrac{\varepsilon_0}{d}$.

$$\frac{\varepsilon_0}{d} = \text{slope} \quad \rightarrow$$

$$d = \frac{\varepsilon_0}{\text{slope}}$$

$$= \frac{8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2}{8606 \times 10^{-12} \text{ F/m}^2}$$

$$= 1.03 \times 10^{-3} \text{ m} \approx \boxed{1.0 \text{ mm}}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH24.XLS," on tab "Problem 24.98."

CHAPTER 25: Electric Currents and Resistance

Responses to Questions

1. A battery rating in ampere-hours gives the total amount of charge available in the battery.

2. The chemical reactions within the cell cause electrons to pile up on the negative electrode. If the terminals of the battery are connected in a circuit, then electrons flow from the negative terminal because it has an excess of electrons. Once the electrons return to the cell, the electrolyte again causes them to move to the negative terminal.

3. When a flashlight is operated, the battery energy is being used up.

4. The terminal of the car battery connected to "ground" is actually connected to the metal frame of the car. This provides a large "sink" or "source" for charge. The metal frame serves as the common ground for all electrical devices in the car, and all voltages are measured with respect to the car's frame.

5. Generally, water is already in the faucet spout, but it will not come out until the faucet valve is opened. Opening the valve provides the pressure difference needed to force water out of the spout. The same thing is essentially true when you connect a wire to the terminals of a battery. Electrons already exist in the wires. The battery provides the potential that causes them to move, producing a current.

6. Yes. They might have the same resistance if the aluminum wire is thicker. If the lengths of the wires are the same, then the ratios of resistivity to cross-sectional area must also be the same for the resistances to be the same. Aluminum has a higher resistivity than copper, so if the cross-sectional area of the aluminum is also larger by the same proportion, the two wires will have the same resistance.

7. If the emf in a circuit remains constant and the resistance in the circuit is increased, less current will flow, and the power dissipated in the circuit will decrease. Both power equations support this result. If the current in a circuit remains constant and the resistance is increased, then the emf must increase and the power dissipated in the circuit will increase. Both equations also support this result. There is no contradiction, because the voltage, current, and resistance are related to each other by $V = IR$.

8. When a lightbulb burns out, the filament breaks, creating a gap in the circuit so that no current flows.

9. If the resistance of a small immersion heater were increased, it would slow down the heating process. The emf in the circuit made up of the heater and the wires that connect it to the wall socket is maintained at a constant rms value. If the resistance in the circuit is increased, less current will flow, and the power dissipated in the circuit will decrease, slowing the heating process.

10. Resistance is proportional to length and inversely proportional to cross-sectional area.
    (*a*) For the least resistance, you want to connect the wires to maximize area and minimize length. Therefore, connect them opposite to each other on the faces that are $2a$ by $3a$.
    (*b*) For the greatest resistance, you want to minimize area and maximize length. Therefore, connect the wires to the faces that are $1a$ by $2a$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11. When a light is turned on, the filament is cool, and has a lower resistance than when it is hot. The current through the filament will be larger, due to the lower resistance. This momentary high current will heat the wire rapidly, possibly causing the filament to break due to thermal stress or vaporize. After the light has been on for some time, the filament is at a constant high temperature, with a higher resistance and a lower current. Since the temperature is constant, there is less thermal stress on the filament than when the light is first turned on.

12. When connected to the same potential difference, the 100-W bulb will draw more current ($P = IV$). The 75-W bulb has the higher resistance ($V = IR$ or $P = V^2/R$).

13. The electric power transferred by the lines is $P = IV$. If the voltage across the transmission lines is large, then the current in the lines will be small. The power lost in the transmission lines is $P = I^2R$. The power dissipated in the lines will be small, because I is small.

14. If the circuit has a 15-A fuse, then it is rated to carry current of no more than 15 A. Replacing the 15-A fuse with a 25-A fuse will allow the current to increase to a level that is dangerously high for the wiring, which might result in overheating and possibly a fire.

15. The human eye and brain cannot distinguish the on-off cycle of lights when they are operated at the normal 60 Hz frequency. At much lower frequencies, such as 5 Hz, the eye and brain are able to process the on-off cycle of the lights, and they will appear to flicker.

16. The electrons are not "used up" as they pass through the lamp. Their energy is dissipated as light and heat, but with each cycle of the alternating voltage, their potential energy is raised again. As long as the electrons keep moving (converting potential energy into kinetic energy, light, and heat) the lamp will stay lit.

17. Immediately after the toaster is turned on, the Nichrome wire heats up and its resistance increases. Since the (rms) potential across the element remains constant, the current in the heating element must decrease.

18. No. Energy is dissipated in a resistor but current, the rate of flow of charge, is not "used up."

19. In the two wires described, the drift velocities of the electrons will be about the same, but the current density, and therefore the current, in the wire with twice as many free electrons per atom will be twice as large as in the other wire.

20. (*a*) If the length of the wire doubles, its resistance also doubles, and so the current in the wire will be reduced by a factor of two. Drift velocity is proportional to current, so the drift velocity will be halved.
    (*b*) If the wire's radius is doubled, the drift velocity remains the same. (Although, since there are more charge carriers, the current will quadruple.)
    (*c*) If the potential difference doubles while the resistance remains constant, the drift velocity and current will also double.

21. If you turn on an electric appliance when you are outside with bare feet, and the appliance shorts out through you, the current has a direct path to ground through your feet, and you will receive a severe shock. If you are inside wearing socks and shoes with thick soles, and the appliance shorts out, the current will not have an easy path to ground through you, and will most likely find an alternate path. You might receive a mild shock, but not a severe one.

Solutions to Problems

1. Use the definition of current, Eq. 25-1a.

$$I = \frac{\Delta Q}{\Delta t} \rightarrow 1.30\,\text{A} = \frac{1.30\,\text{C}}{\text{s}} \times \frac{1\ \text{electron}}{1.60\times10^{-19}\,\text{C}} = \boxed{8.13\times10^{18}\ \text{electrons/s}}$$

2. Use the definition of current, Eq. 25-1a.

$$I = \frac{\Delta Q}{\Delta t} \rightarrow \Delta Q = I\Delta t = (6.7\,\text{A})(5.0\,\text{h})(3600\,\text{s/h}) = \boxed{1.2\times10^{5}\,\text{C}}$$

3. Use the definition of current, Eq. 25-1a.

$$I = \frac{\Delta Q}{\Delta t} = \frac{(1200\ \text{ions})(1.60\times10^{-19}\,\text{C/ion})}{3.5\times10^{-6}\,\text{s}} = \boxed{5.5\times10^{-11}\,\text{A}}$$

4. Solve Eq. 25-2a for resistance.

$$R = \frac{V}{I} = \frac{120\,\text{V}}{4.2\,\text{A}} = \boxed{29\,\Omega}$$

5. (*a*) Use Eq. 25-2b to find the current.

$$V = IR \rightarrow I = \frac{V}{R} = \frac{240\,\text{V}}{8.6\,\Omega} = 27.91\,\text{A} \approx \boxed{28\,\text{A}}$$

(*b*) Use the definition of current, Eq. 25-1a.

$$I = \frac{\Delta Q}{\Delta t} \rightarrow \Delta Q = I\Delta t = (27.91\,\text{A})(50\,\text{min})(60\,\text{s/min}) = \boxed{8.4\times10^{4}\,\text{C}}$$

6. (*a*) Solve Eq. 25-2a for resistance.

$$R = \frac{V}{I} = \frac{120\,\text{V}}{9.5\,\text{A}} = 12.63\,\Omega \approx \boxed{13\,\Omega}$$

(*b*) Use the definition of average current, Eq. 25-1a.

$$I = \frac{\Delta Q}{\Delta t} \rightarrow \Delta Q = I\Delta t = (9.5\,\text{A})(15\,\text{min})(60\,\text{s/min}) = \boxed{8600\,\text{C}}$$

7. Use Ohm's Law, Eq. 25-2a, to find the current. Then use the definition of current, Eq. 25-1a, to calculate the number of electrons per minute.

$$I = \frac{V}{R} = \frac{\Delta Q}{\Delta t} = \frac{4.5\,\text{V}}{1.6\,\Omega} = \frac{2.8\,\text{C}}{\text{s}} \times \frac{1\ \text{electron}}{1.60\times10^{-19}\,\text{C}} \times \frac{60\,\text{s}}{1\,\text{min}} = \boxed{1.1\times10^{21}\,\frac{\text{electrons}}{\text{minute}}}$$

8. Find the potential difference from the resistance and the current.

$$R = (2.5\times10^{-5}\,\Omega/\text{m})(4.0\times10^{-2}\,\text{m}) = 1.0\times10^{-6}\,\Omega$$

$$V = IR = (3100\,\text{A})(1.0\times10^{-6}\,\Omega) = \boxed{3.1\times10^{-3}\,\text{V}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9. (*a*) Use Eq. 25-2b to find the resistance.

$$R = \frac{V}{I} = \frac{12\,\text{V}}{0.60\,\text{A}} = \boxed{20\,\Omega} \text{ (2 sig. fig.)}$$

(*b*) An amount of charge ΔQ loses a potential energy of $(\Delta Q)V$ as it passes through the resistor. The amount of charge is found from Eq. 25-1a.

$$\Delta U = (\Delta Q)V = (I\Delta t)V = (0.60\,\text{A})(60\,\text{s})(12\,\text{V}) = \boxed{430\,\text{J}}$$

10. (*a*) If the voltage drops by 15%, and the resistance stays the same, then by Eq. 25-2b, $V = IR$, the current will also drop by 15%.

$$I_{\text{final}} = 0.85 I_{\text{initial}} = 0.85(6.50\,\text{A}) = 5.525\,\text{A} \approx \boxed{5.5\,\text{A}}$$

(*b*) If the resistance drops by 15% (the same as being multiplied by 0.85), and the voltage stays the same, then by Eq. 25-2b, the current must be divided by 0.85.

$$I_{\text{final}} = \frac{I_{\text{initial}}}{0.85} = \frac{6.50\,\text{A}}{0.85} = 7.647\,\text{A} \approx \boxed{7.6\,\text{A}}$$

11. Use Eq. 25-3 to find the diameter, with the area as $A = \pi r^2 = \pi d^2/4$.

$$R = \rho\frac{\ell}{A} = \rho\frac{4\ell}{\pi d^2} \quad \rightarrow \quad d = \sqrt{\frac{4\ell\rho}{\pi R}} = \sqrt{\frac{4(1.00\,\text{m})(5.6\times10^{-8}\,\Omega\cdot\text{m})}{\pi(0.32\,\Omega)}} = \boxed{4.7\times10^{-4}\,\text{m}}$$

12. Use Eq. 25-3 to calculate the resistance, with the area as $A = \pi r^2 = \pi d^2/4$.

$$R = \rho\frac{\ell}{A} = \rho\frac{4\ell}{\pi d^2} = (1.68\times10^{-8}\,\Omega\cdot\text{m})\frac{4(4.5\,\text{m})}{\pi(1.5\times10^{-3}\,\text{m})^2} = \boxed{4.3\times10^{-2}\,\Omega}$$

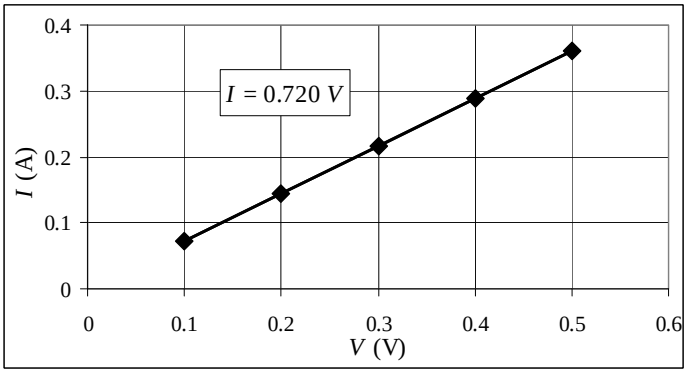
13. Use Eq. 25-3 to calculate the resistances, with the area as $A = \pi r^2 = \pi d^2/4$.

$$R = \rho\frac{\ell}{A} = \rho\frac{4\ell}{\pi d^2}.$$

$$\frac{R_{\text{Al}}}{R_{\text{Cu}}} = \frac{\rho_{\text{Al}}\dfrac{4\ell_{\text{Al}}}{\pi d_{\text{Al}}^2}}{\rho_{\text{Cu}}\dfrac{4\ell_{\text{Cu}}}{\pi d_{\text{Cu}}^2}} = \frac{\rho_{\text{Al}}\ell_{\text{Al}}d_{\text{Cu}}^2}{\rho_{\text{Cu}}\ell_{\text{Cu}}d_{\text{Al}}^2} = \frac{(2.65\times10^{-8}\,\Omega\cdot\text{m})(10.0\,\text{m})(1.8\,\text{mm})^2}{(1.68\times10^{-8}\,\Omega\cdot\text{m})(20.0\,\text{m})(2.0\,\text{mm})^2} = \boxed{0.64}$$

14. Use Eq. 25-3 to express the resistances, with the area as $A = \pi r^2 = \pi d^2/4$, and so $R = \rho\dfrac{\ell}{A} = \rho\dfrac{4\ell}{\pi d^2}$.

$$R_{\text{W}} = R_{\text{Cu}} \quad \rightarrow \quad \rho_{\text{W}}\frac{4\ell}{\pi d_{\text{W}}^2} = \rho_{\text{Cu}}\frac{4\ell}{\pi d_{\text{Cu}}^2} \quad \rightarrow$$



$$d_{\text{W}} = d_{\text{Cu}}\sqrt{\frac{\rho_{\text{W}}}{\rho_{\text{Cu}}}} = (2.2\,\text{mm})\sqrt{\frac{5.6\times10^{-8}\,\Omega\cdot\text{m}}{1.68\times10^{-8}\,\Omega\cdot\text{m}}} = \boxed{4.0\,\text{mm}}$$

The diameter of the tungsten should be 4.0 mm.

15. (*a*) If the wire obeys Ohm's law, then $V = IR$ or $I = \dfrac{1}{R}V,$ showing a linear relationship between I and V. A graph of I vs. V should give a straight line with a slope of $\dfrac{1}{R}$ and a y-intercept of 0.

(*b*) From the graph and the calculated linear fit, we see that the wire obeys Ohm's law.

$$\text{slope} = \frac{1}{R} \quad \rightarrow$$

$$R = \frac{1}{0.720}\,\text{A/V}$$

$$= \boxed{1.39\,\Omega}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH25.XLS," on tab "Problem 25.15b."

(*c*) Use Eq. 25-3 to find the resistivity.

$$R = \rho\frac{\ell}{A} \quad \rightarrow \quad \rho = \frac{AR}{\ell} = \frac{\pi d^2 R}{4\ell} = \frac{\pi\left(3.2\times10^{-4}\,\text{m}\right)^2\left(1.39\,\Omega\right)}{4\left(0.11\,\text{m}\right)} = \boxed{1.0\times10^{-6}\,\Omega\bullet\text{m}}$$

From Table 25-1, the material is nichrome.

16. Use Eq. 25-5 multiplied by ℓ/A so that it expresses resistance instead of resistivity.

$$R = R_0\left[1+\alpha\left(T-T_0\right)\right] = 1.15R_0 \quad \rightarrow \quad 1+\alpha\left(T-T_0\right) = 1.15 \quad \rightarrow$$

$$T - T_0 = \frac{0.15}{\alpha} = \frac{0.15}{.0068\left(\text{C}^\circ\right)^{-1}} = \boxed{22\,\text{C}^\circ}$$

So raise the temperature by $22\,\text{C}^\circ$ to a final temperature of $42°\text{C}$.

17. Since the resistance is directly proportional to the length, the length of the long piece must be 4.0 times the length of the short piece.

$$\ell = \ell_{\text{short}} + \ell_{\text{long}} = \ell_{\text{short}} + 4.0\ell_{\text{short}} = 5.0\ell_{\text{short}} \quad \rightarrow \quad \ell_{\text{short}} = 0.20\ell\,,\ \ell_{\text{long}} = 0.80\ell$$

Make the cut at 20% of the length of the wire.

$$\ell_{\text{short}} = 0.20\ell\,,\ \ell_{\text{long}} = 0.80\ell \quad \rightarrow \quad R_{\text{short}} = 0.2R = \boxed{2.0\,\Omega}\,,\ R_{\text{long}} = 0.8R = \boxed{8.0\,\Omega}$$

18. Use Eq. 25-5 for the resistivity.

$$\rho_{\text{T Al}} = \rho_{0\,\text{Al}}\left[1+\alpha_{\text{Al}}\left(T-T_0\right)\right] = \rho_{0\,\text{W}} \quad \rightarrow$$

$$T = T_0 + \frac{1}{\alpha_{\text{Al}}}\left(\frac{\rho_{0\,\text{W}}}{\rho_{0\,\text{Al}}} - 1\right) = 20°\text{C} + \frac{1}{0.00429\left(\text{C}^\circ\right)^{-1}}\left(\frac{5.6\times10^{-8}\,\Omega\bullet\text{m}}{2.65\times10^{-8}\,\Omega\bullet\text{m}} - 1\right) = 279.49°\text{C} \approx \boxed{280°\text{C}}$$

19. Use Eq. 25-5 multiplied by ℓ/A so that it expresses resistances instead of resistivity.

$$R = R_0\left[1+\alpha\left(T-T_0\right)\right] \quad \rightarrow$$

$$T = T_0 + \frac{1}{\alpha}\left(\frac{R}{R_0} - 1\right) = 20°\text{C} + \frac{1}{0.0045\left(\text{C}^\circ\right)^{-1}}\left(\frac{140\,\Omega}{12\,\Omega} - 1\right) = 2390°\text{C} \approx \boxed{2400°\text{C}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

20. Calculate the voltage drop by combining Ohm's Law (Eq. 25-2b) with the expression for resistance, Eq. 25-3.

$$V = IR = I\frac{\rho\ell}{A} = I\frac{4\rho\ell}{\pi d^2} = (12\,\text{A})\frac{4\left(1.68\times10^{-8}\,\Omega\text{•m}\right)(26\,\text{m})}{\pi\left(1.628\times10^{-3}\,\text{m}\right)^2} = \boxed{2.5\,\text{V}}$$

21. The wires have the same resistance and the same resistivity.

$$R_{\text{long}} = R_{\text{short}} \;\rightarrow\; \frac{\rho\ell_{\text{long}}}{A_1} = \frac{\rho\ell_{\text{short}}}{A_2} \;\rightarrow\; \frac{(4)2\ell_{\text{short}}}{\pi d_{\text{long}}^2} = \frac{4\ell_{\text{short}}}{\pi d_{\text{short}}^2} \;\rightarrow\; \boxed{\frac{d_{\text{long}}}{d_{\text{short}}} = \sqrt{2}}$$

22. In each case calculate the resistance by using Eq. 25-3 for resistance.

(*a*) $R_x = \dfrac{\rho\ell_x}{A_{yz}} = \dfrac{\left(3.0\times10^{-5}\,\Omega\text{•m}\right)\left(1.0\times10^{-2}\,\text{m}\right)}{\left(2.0\times10^{-2}\,\text{m}\right)\left(4.0\times10^{-2}\,\text{m}\right)} = 3.75\times10^{-4}\,\Omega \approx \boxed{3.8\times10^{-4}\,\Omega}$

(*b*) $R_y = \dfrac{\rho\ell_y}{A_{xz}} = \dfrac{\left(3.0\times10^{-5}\,\Omega\text{•m}\right)\left(2.0\times10^{-2}\,\text{m}\right)}{\left(1.0\times10^{-2}\,\text{m}\right)\left(4.0\times10^{-2}\,\text{m}\right)} = \boxed{1.5\times10^{-3}\,\Omega}$

(*c*) $R_z = \dfrac{\rho\ell_z}{A_{xy}} = \dfrac{\left(3.0\times10^{-5}\,\Omega\text{•m}\right)\left(4.0\times10^{-2}\,\text{m}\right)}{\left(1.0\times10^{-2}\,\text{m}\right)\left(2.0\times10^{-2}\,\text{m}\right)} = \boxed{6.0\times10^{-3}\,\Omega}$

23. The original resistance is $R_0 = V/I_0$, and the high temperature resistance is $R = V/I$, where the two voltages are the same. The two resistances are related by Eq. 25-5, multiplied by ℓ/A so that it expresses resistance instead of resistivity.

$$R = R_0\left[1+\alpha\left(T-T_0\right)\right] \;\rightarrow\; T = T_0 + \frac{1}{\alpha}\left(\frac{R}{R_0}-1\right) = T_0 + \frac{1}{\alpha}\left(\frac{V/I}{V/I_0}-1\right) = T_0 + \frac{1}{\alpha}\left(\frac{I_0}{I}-1\right)$$

$$= 20.0^\circ\text{C} + \frac{1}{0.00429\left(\text{C}^\circ\right)^{-1}}\left(\frac{0.4212\,\text{A}}{0.3818\,\text{A}}-1\right) = \boxed{44.1^\circ\text{C}}$$

24. For the cylindrical wire, its (constant) volume is given by $V = \ell_0 A_0 = \ell A$, and so $A = \dfrac{V}{\ell}$. Combine this relationship with Eq. 25-3. We assume that $\Delta\ell \ll \ell_0$.

$$R_0 = \rho\frac{\ell_0}{A_0} = \rho\frac{\ell_0^2}{V_0} \;;\; R = \rho\frac{\ell}{A} = \rho\frac{\ell^2}{V_0} \;;\; \frac{dR}{d\ell} = 2\rho\frac{\ell}{V_0}$$

$$\Delta R \approx \frac{dR}{d\ell}\Delta\ell = 2\rho\frac{\ell}{V_0}\Delta\ell \;\rightarrow\; \Delta\ell = \frac{V_0\Delta R}{2\rho\ell} \;\rightarrow\; \frac{\Delta\ell}{\ell} = \frac{V_0\Delta R}{2\rho\ell^2} = \frac{\Delta R}{2\dfrac{\rho\ell^2}{V_0}} = \tfrac{1}{2}\frac{\Delta R}{R}$$

This is true for any initial conditions, and so $\boxed{\dfrac{\Delta\ell}{\ell_0} = \tfrac{1}{2}\dfrac{\Delta R}{R_0}}$

25. The resistance depends on the length and area as $R = \rho\ell/A$. Cutting the wire and running the wires side by side will halve the length and double the area.

$$R_2 = \frac{\rho\left(\frac{1}{2}\ell\right)}{2A} = \frac{1}{4}\frac{\rho\ell}{A} = \boxed{\tfrac{1}{4}R_1}$$

26. The total resistance is to be 3700 ohms $\left(R_{\text{total}}\right)$ at all temperatures. Write each resistance in terms of Eq.25-5 (with $T_0 = 0^\circ\text{C}$), multiplied by ℓ/A to express resistance instead of resistivity.

$$R_{\text{total}} = R_{0\text{C}}\left[1+\alpha_{\text{C}}T\right] + R_{0\text{N}}\left[1+\alpha_{\text{N}}T\right] = R_{0\text{C}} + R_{0\text{C}}\alpha_{\text{C}}T + R_{0\text{N}} + R_{0\text{N}}\alpha_{\text{N}}T$$
$$= R_{0\text{C}} + R_{0\text{N}} + \left(R_{0\text{C}}\alpha_{\text{C}} + R_{0\text{N}}\alpha_{\text{N}}\right)T$$

For the above to be true, the terms with a temperature dependence must cancel, and the terms without a temperature dependence must add to R_{total}. Thus we have two equations in two unknowns.

$$0 = \left(R_{0\text{C}}\alpha_{\text{C}} + R_{0\text{N}}\alpha_{\text{N}}\right)T \;\rightarrow\; R_{0\text{N}} = -\frac{R_{0\text{C}}\alpha_{\text{C}}}{\alpha_{\text{N}}}$$

$$R_{\text{total}} = R_{0\text{C}} + R_{0\text{N}} = R_{0\text{C}} - \frac{R_{0\text{C}}\alpha_{\text{C}}}{\alpha_{\text{N}}} = \frac{R_{0\text{C}}\left(\alpha_{\text{N}} - \alpha_{\text{C}}\right)}{\alpha_{\text{N}}} \;\rightarrow$$

$$R_{0\text{C}} = R_{\text{total}}\frac{\alpha_{\text{N}}}{\left(\alpha_{\text{N}} - \alpha_{\text{C}}\right)} = \left(3700\,\Omega\right)\frac{0.0004\left(\text{C}^\circ\right)^{-1}}{0.0004\left(\text{C}^\circ\right)^{-1} + 0.0005\left(\text{C}^\circ\right)^{-1}} = 1644\,\Omega \approx \boxed{1600\,\Omega}$$

$$R_{0\text{N}} = R_{\text{total}} - R_{0\text{C}} = 3700\,\Omega - 1644\,\Omega = 2056\,\Omega \approx \boxed{2100\,\Omega}$$

27. We choose a spherical shell of radius *r* and thickness *dr* as a differential element. The area of this element is $4\pi r^2$. Use Eq. 25-3, but for an infinitesimal resistance. Then integrate over the radius of the sphere.

$$R = \rho\frac{\ell}{A} \;\rightarrow\; dR = \rho\frac{d\ell}{A} = \frac{dr}{4\pi\sigma r^2} \;\rightarrow\; R = \int dR = \int_{r_1}^{r_2}\frac{dr}{4\pi\sigma r^2} = \frac{1}{4\pi\sigma}\left(-\frac{1}{r}\right)_{r_1}^{r_2} = \boxed{\frac{1}{4\pi\sigma}\left(\frac{1}{r_1} - \frac{1}{r_2}\right)}$$

28. (*a*) Let the values at the lower temperature be indicated by a subscript "0". Thus $R_0 = \rho_0\frac{\ell_0}{A_0}$

$= \rho_0\frac{4\ell_0}{\pi d_0^2}$. The change in temperature results in new values for the resistivity, the length, and the diameter. Let α represent the temperature coefficient for the resistivity, and α_{T} represent the thermal coefficient of expansion, which will affect the length and diameter.

$$R = \rho\frac{\ell}{A} = \rho\frac{4\ell}{\pi d^2} = \rho_0\left[1+\alpha\left(T-T_0\right)\right]\frac{4\ell_0\left[1+\alpha_{\text{T}}\left(T-T_0\right)\right]}{\pi\left\{d_0\left[1+\alpha_{\text{T}}\left(T-T_0\right)\right]\right\}^2} = \rho_0\frac{4\ell_0}{\pi d_0^2}\frac{\left[1+\alpha\left(T-T_0\right)\right]}{\left[1+\alpha_{\text{T}}\left(T-T_0\right)\right]}$$

$$= R_0\frac{\left[1+\alpha\left(T-T_0\right)\right]}{\left[1+\alpha_{\text{T}}\left(T-T_0\right)\right]} \;\rightarrow\; R\left[1+\alpha_{\text{T}}\left(T-T_0\right)\right] = R_0\left[1+\alpha\left(T-T_0\right)\right] \;\rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$T = T_0 + \frac{(R - R_0)}{(R_0\alpha - R\alpha_T)} = 20°\text{C} + \frac{(140\,\Omega - 12\,\Omega)}{\left[(12\,\Omega)\left(0.0045\,\text{C}^{\circ -1}\right) - (140\,\Omega)\left(5.5\times10^{-6}\,\text{C}^{\circ -1}\right)\right]}$$

$$= 20°\text{C} + 2405°\text{C} = 2425°\text{C} \approx \boxed{2400°\text{C}}$$

(*b*) The net effect of thermal expansion is that both the length and diameter increase, which lowers the resistance.

$$\frac{R}{R_0} = \frac{\rho_0 \dfrac{4\ell}{\pi d^2}}{\rho_0 \dfrac{4\ell_0}{\pi d_0^2}} = \frac{\ell d_0^2}{\ell_0 d^2} = \frac{\ell_0\left[1 + \alpha_T (T - T_0)\right]}{\ell_0} \frac{d_0^2}{\left\{d_0\left[1 + \alpha_T (T - T_0)\right]\right\}^2} = \frac{1}{\left[1 + \alpha_T (T - T_0)\right]}$$

$$= \frac{1}{\left[1 + \left(5.5\times10^{-6}\,\text{C}^{\circ -1}\right)(2405°\text{C})\right]} = 0.9869$$

$$\%\,\text{change} = \left(\frac{R - R_0}{R_0}\right)100 = \left(\frac{R}{R_0} - 1\right)100 = -1.31 \approx \boxed{-1.3\%}$$

The net effect of resistivity change is that the resistance increases.

$$\frac{R}{R_0} = \frac{\rho \dfrac{4\ell_0}{\pi d_0^2}}{\rho_0 \dfrac{4\ell_0}{\pi d_0^2}} = \frac{\rho}{\rho_0} = \frac{\rho_0\left[1 + \alpha(T - T_0)\right]}{\rho_0} = \left[1 + \alpha(T - T_0)\right] = \left[1 + \left(0.0045\,\text{C}^{\circ -1}\right)(2405°\text{C})\right]$$

$$= 11.82$$

$$\%\,\text{change} = \left(\frac{R - R_0}{R_0}\right)100 = \left(\frac{R}{R_0} - 1\right)100 = 1082 \approx \boxed{1100\%}$$

29. (*a*) Calculate each resistance separately using Eq. 25-3, and then add the resistances together to find the total resistance.

$$R_{Cu} = \frac{\rho_{Cu}\ell}{A} = \frac{4\rho_{Cu}\ell}{\pi d^2} = \frac{4\left(1.68\times10^{-8}\,\Omega\bullet\text{m}\right)(5.0\,\text{m})}{\pi\left(1.4\times10^{-3}\,\text{m}\right)^2} = 0.054567\,\Omega$$

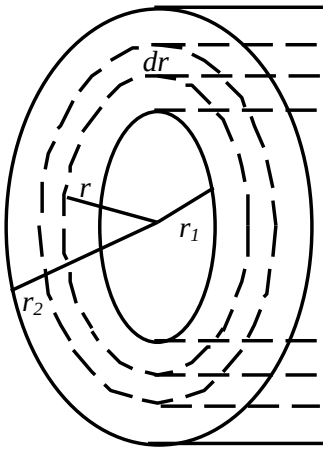
$$R_{Al} = \frac{\rho_{Al}\ell}{A} = \frac{4\rho_{Al}\ell}{\pi d^2} = \frac{4\left(2.65\times10^{-8}\,\Omega\bullet\text{m}\right)(5.0\,\text{m})}{\pi\left(1.4\times10^{-3}\,\text{m}\right)^2} = 0.086074\,\Omega$$

$$R_{total} = R_{Cu} + R_{Al} = 0.054567\,\Omega + 0.086074\,\Omega = 0.140641\,\Omega \approx \boxed{0.14\,\Omega}$$

(*b*) The current through the wire is the voltage divided by the total resistance.

$$I = \frac{V}{R_{total}} = \frac{85\times10^{-3}\,\text{V}}{0.140641\,\Omega} = 0.60438\,\text{A} \approx \boxed{0.60\,\text{A}}$$

(*c*) For each segment of wire, Ohm's law is true. Both wires have the current found in (*b*) above.



$$V_{Cu} = IR_{Cu} = (0.60438\,\text{A})(0.054567\,\Omega) \approx \boxed{0.033\,\text{V}}$$

$$V_{Al} = IR_{Al} = (0.60438\,\text{A})(0.086074\,\Omega) \approx \boxed{0.052\,\text{V}}$$

Notice that the total voltage is 85 mV.

30. (*a*) Divide the cylinder up into concentric cylindrical shells of radius *r*, thickness *dr*, and length ℓ. See the diagram. The resistance of one of those shells, from Eq. 25-3, is found. Note that the "length" in Eq. 25-3 is in the direction of the current flow, so we must substitute in *dr* for the "length" in Eq. 25-3. The area is the surface area of the thin cylindrical shell. Then integrate over the range of radii to find the total resistance.

$$R = \rho\frac{\text{"}\ell\text{"}}{A} \quad \rightarrow \quad dR = \rho\frac{dr}{2\pi r\ell} \;;$$

$$R = \int dR = \int_{r_1}^{r_2} \rho\frac{dr}{2\pi r\ell} = \boxed{\frac{\rho}{2\pi\ell}\ln\frac{r_2}{r_1}}$$

(*b*) Use the data given to calculate the resistance from the above formula.

$$R = \frac{\rho}{2\pi\ell}\ln\frac{r_2}{r_1} = \frac{15\times10^{-5}\,\Omega\cdot\text{m}}{2\pi(0.024\,\text{m})}\ln\left(\frac{1.8\,\text{mm}}{1.0\,\text{mm}}\right) = \boxed{5.8\times10^{-4}\,\Omega}$$

(*c*) For resistance along the axis, we again use Eq. 25-3, but the current is flowing in the direction of length ℓ. The area is the cross-sectional area of the face of the hollow cylinder.

$$R = \frac{\rho\ell}{A} = \frac{\rho\ell}{\pi\left(r_2^2 - r_1^2\right)} = \frac{\left(15\times10^{-5}\,\Omega\cdot\text{m}\right)(0.024\,\text{m})}{\pi\left[\left(1.8\times10^{-3}\,\text{m}\right)^2 - \left(1.0\times10^{-3}\,\text{m}\right)^2\right]} = \boxed{0.51\,\Omega}$$

31. Use Eq. 25-6 to find the power from the voltage and the current.

$$P = IV = (0.27\,\text{A})(3.0\,\text{V}) = \boxed{0.81\,\text{W}}$$

32. Use Eq. 25-7b to find the resistance from the voltage and the power.

$$P = \frac{V^2}{R} \quad \rightarrow \quad R = \frac{V^2}{P} = \frac{(240\,\text{V})^2}{3300\,\text{W}} = \boxed{17\,\Omega}$$

33. Use Eq. 25-7b to find the voltage from the power and the resistance.

$$P = \frac{V^2}{R} \quad \rightarrow \quad V = \sqrt{RP} = \sqrt{(3300\,\Omega)(0.25\,\text{W})} = \boxed{29\,\text{V}}$$

34. Use Eq. 25-7b to find the resistance, and Eq. 25-6 to find the current.

(*a*) $$P = \frac{V^2}{R} \quad \rightarrow \quad R = \frac{V^2}{P} = \frac{(110\,\text{V})^2}{75\,\text{W}} = 161.3\,\Omega \approx \boxed{160\,\Omega}$$

$$P = IV \quad \rightarrow \quad I = \frac{P}{V} = \frac{75\,\text{W}}{110\,\text{V}} = 0.6818\,\text{A} \approx \boxed{0.68\,\text{A}}$$

(*b*) $$P = \frac{V^2}{R} \quad \rightarrow \quad R = \frac{V^2}{P} = \frac{(110\,\text{V})^2}{440\,\text{W}} = 27.5\,\Omega \approx \boxed{28\,\Omega}$$

$$P = IV \quad \rightarrow \quad I = \frac{P}{V} = \frac{440\,\text{W}}{110\,\text{V}} = \boxed{4.0\,\text{A}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35. (*a*) From Eq. 25-6, if power *P* is delivered to the transmission line at voltage *V*, there must be a current $I = P/V$. As this current is carried by the transmission line, there will be power losses of I^2R due to the resistance of the wire. This power loss can be expressed as $\Delta P = I^2R = \boxed{P^2R/V^2}$. Equivalently, there is a voltage drop across the transmission lines of $V' = IR$. Thus the voltage available to the users is $V - V'$, and so the power available to the users is $P' = (V - V')I = VI - V'I = VI - I^2R = P - I^2R$. The power loss is $\Delta P = P - P' = P - \left(P - I^2R\right) = I^2R = \boxed{P^2R/V^2}$.

(*b*) Since $\Delta P \propto \dfrac{1}{V^2}$, *V* should be <u>as large as possible</u> to minimize ΔP.

36. (*a*) Since $P = \dfrac{V^2}{R} \rightarrow R = \dfrac{V^2}{P}$ says that the resistance is inversely proportional to the power for a constant voltage, we predict that the 850 W setting has the higher resistance.

(*b*) $R = \dfrac{V^2}{P} = \dfrac{(120\,\text{V})^2}{850\,\text{W}} = \boxed{17\,\Omega}$

(*c*) $R = \dfrac{V^2}{P} = \dfrac{(120\,\text{V})^2}{1250\,\text{W}} = \boxed{12\,\Omega}$

37. (*a*) Use Eq. 25-6 to find the current.

$$P = IV \rightarrow I = \frac{P}{V} = \frac{95\,\text{W}}{115\,\text{V}} = \boxed{0.83\,\text{A}}$$

(*b*) Use Eq. 25-7b to find the resistance.

$$P = \frac{V^2}{R} \rightarrow R = \frac{V^2}{P} = \frac{(115\,\text{V})^2}{95\,\text{W}} \approx \boxed{140\,\Omega}$$

38. The power (and thus the brightness) of the bulb is proportional to the square of the voltage, according to Eq. 25-7b, $P = \dfrac{V^2}{R}$. Since the resistance is assumed to be constant, if the voltage is cut in half from 240 V to 120V, the power will be reduced by a factor of 4. Thus the bulb will appear only about <u>1/4 as bright</u> in the United States as in Europe.

39. To find the kWh of energy, multiply the kilowatts of power consumption by the number of hours in operation.

$$\text{Energy} = P(\text{in kW})\,t(\text{in h}) = (550\,\text{W})\left(\frac{1\,\text{kW}}{1000\,\text{W}}\right)(6.0\,\text{min})\left(\frac{1\,\text{h}}{60\,\text{min}}\right) = \boxed{0.055\,\text{kWh}}$$

To find the cost of the energy used in a month, multiply times 4 days per week of usage, times 4 weeks per month, times the cost per kWh.

$$\text{Cost} = \left(0.055\frac{\text{kWh}}{\text{d}}\right)\left(\frac{4\,\text{d}}{1\,\text{week}}\right)\left(\frac{4\,\text{week}}{1\,\text{month}}\right)\left(\frac{9.0\,\text{cents}}{\text{kWh}}\right) = \boxed{7.9\,\text{cents/month}}$$

40. To find the cost of the energy, multiply the kilowatts of power consumption by the number of hours in operation times the cost per kWh.

$$\text{Cost} = (25\,\text{W})\left(\frac{1\,\text{kW}}{1000\,\text{W}}\right)(365\,\text{day})\left(\frac{24\,\text{h}}{1\,\text{day}}\right)\left(\frac{\$0.095}{\text{kWh}}\right) \approx \boxed{\$21}$$

41. The A•h rating is the amount of charge that the battery can deliver. The potential energy of the charge is the charge times the voltage.

$$U = QV = (75\,\text{A•h})\left(\frac{3600\,\text{s}}{1\,\text{h}}\right)(12\,\text{V}) = \boxed{3.2\times10^6\,\text{J}} = 0.90\,\text{kWh}$$

42. (*a*) Calculate the resistance from Eq. 25-2b and the power from Eq. 25-6.

$$R = \frac{V}{I} = \frac{3.0\,\text{V}}{0.38\,\text{A}} = 7.895\,\Omega \approx \boxed{7.9\,\Omega} \qquad P = IV = (0.38\,\text{A})(3.0\,\text{V}) = 1.14\,\text{W} \approx \boxed{1.1\,\text{W}}$$

(*b*) If four D-cells are used, the voltage will be doubled to 6.0 V. Assuming that the resistance of the bulb stays the same (by ignoring heating effects in the filament), the power that the bulb would need to dissipate is given by Eq. 25-7b, $P = \dfrac{V^2}{R}$. A doubling of the voltage means the power is increased by a factor of $\boxed{4}$. This should not be tried because the bulb is probably not rated for such a high wattage. The filament in the bulb would probably burn out, and the glass bulb might even explode if the filament burns violently.

43. Each bulb will draw an amount of current found from Eq. 25-6.

$$P = IV \;\rightarrow\; I_{\text{bulb}} = \frac{P}{V}$$

The number of bulbs to draw 15 A is the total current divided by the current per bulb.

$$I_{\text{total}} = nI_{\text{bulb}} = n\frac{P}{V} \;\rightarrow\; n = \frac{VI_{\text{total}}}{P} = \frac{(120\,\text{V})(15\,\text{A})}{75\,\text{W}} = \boxed{24\text{ bulbs}}$$

44. Find the power dissipated in the cord by Eq. 25-7a, using Eq. 25-3 for the resistance.

$$P = I^2R = I^2\rho\frac{\ell}{A} = I^2\rho\frac{\ell}{\pi d^2/4} = I^2\rho\frac{4\ell}{\pi d^2} = (15.0\,\text{A})^2\left(1.68\times10^{-8}\,\Omega\text{•m}\right)\frac{4(5.4\,\text{m})}{\pi\left(0.129\times10^{-2}\,\text{m}\right)^2}$$

$$= 15.62\,\text{W} \approx \boxed{16\,\text{W}}$$

45. Find the current used to deliver the power in each case, and then find the power dissipated in the resistance at the given current.

$$P = IV \;\rightarrow\; I = \frac{P}{V} \qquad P_{\text{dissipated}} = I^2R = \frac{P^2}{V^2}R$$

$$P_{\substack{\text{dissipated}\\ 12{,}000\,\text{V}}} = \frac{\left(7.5\times10^5\,\text{W}\right)^2}{\left(1.2\times10^4\,\text{V}\right)^2}(3.0\,\Omega) = 11719\,\text{W}$$

$$P_{\substack{\text{dissipated}\\ 50{,}000\,\text{V}}} = \frac{\left(7.5\times10^5\,\text{W}\right)^2}{\left(5\times10^4\,\text{V}\right)^2}(3.0\,\Omega) = 675\,\text{W} \qquad \text{difference} = 11719\,\text{W} - 675\,\text{W} = \boxed{1.1\times10^4\,\text{W}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

46. (*a*) By conservation of energy and the efficiency claim, 75% of the electrical power dissipated by the heater must be the rate at which energy is absorbed by the water.

$$0.75_{\substack{\text{emitted by}\\ \text{electromagnet}}} = P_{\substack{\text{absorbed}\\ \text{by water}}} \quad \rightarrow \quad 0.75(IV) = \frac{Q_{\text{heat water}}}{t} = \frac{mc\Delta T}{t} \quad \rightarrow$$

$$I = \frac{mc\Delta T}{0.75Vt} = \frac{(0.120\,\text{kg})(4186\,\text{J/kg})(95°\text{C} - 25°\text{C})}{(0.75)(12\,\text{V})(480\,\text{s})} = 8.139\,\text{A} \approx \boxed{8.1\,\text{A}}$$

(*b*) Use Ohm's law to find the resistance of the heater.

$$V = IR \quad \rightarrow \quad R = \frac{V}{I} = \frac{12\,\text{V}}{8.139\,\text{A}} = \boxed{1.5\,\Omega}$$

47. The water temperature rises by absorbing the heat energy that the electromagnet dissipates. Express both energies in terms of power, which is energy per unit time.

$$P_{\text{electric}} = P_{\substack{\text{to heat}\\ \text{water}}} \quad \rightarrow \quad IV = \frac{Q_{\text{heat water}}}{t} = \frac{mc\Delta T}{t} \quad \rightarrow$$

$$\frac{m}{t} = \frac{IV}{c\Delta T} = \frac{(17.5\,\text{A})(240\,\text{V})}{(4186\,\text{J/kg•°C})(6.50\,\text{C°})} = 0.154\ \text{kg/s} \approx \boxed{0.15\,\text{kg/s}}$$

This is $154\,\text{mL/s}$.

48. For the wire to stay a constant temperature, the power generated in the resistor is to be dissipated by radiation. Use Eq. 25-7a and 19-18, both expressions of power (energy per unit time). We assume that the dimensions requested and dimensions given are those at the higher temperature, and do not take any thermal expansion effects into account. We also use Eq. 25-3 for resistance.

$$I^2R = \varepsilon\sigma A\left(T_{\text{high}}^4 - T_{\text{low}}^4\right) \quad \rightarrow \quad I^2\frac{4\rho\ell}{\pi d^2} = \varepsilon\sigma\pi d\ell\left(T_{\text{high}}^4 - T_{\text{low}}^4\right) \quad \rightarrow$$

$$d = \left(\frac{4I^2\rho}{\pi^2\varepsilon\sigma\left(T_{\text{high}}^4 - T_{\text{low}}^4\right)}\right)^{1/3} = \left(\frac{4(15.0\,\text{A})^2\left(5.6\times10^{-8}\,\Omega\text{•m}\right)}{\pi^2(1.0)\left(5.67\times10^{-8}\,\text{W/m}^2\text{•K}^4\right)\left[(3100\,\text{K})^4 - (293\,\text{K})^4\right]}\right)^{1/3}$$

$$= 9.92\times10^{-5}\,\text{m} \approx \boxed{0.099\,\text{mm}}$$

49. Use Ohm's law and the relationship between peak and rms values.

$$I_{\text{peak}} = \sqrt{2}I_{\text{rms}} = \sqrt{2}\frac{V_{\text{rms}}}{R} = \sqrt{2}\frac{220\,\text{V}}{2700\,\Omega} = \boxed{0.12\,\text{A}}$$

50. Find the peak current from Ohm's law, and then find the rms current from Eq. 25-9a.

$$I_{\text{peak}} = \frac{V_{\text{peak}}}{R} = \frac{180\,\text{V}}{380\,\Omega} = 0.47368\,\text{A} \approx \boxed{0.47\,\text{A}} \qquad I_{\text{rms}} = I_{\text{peak}}/\sqrt{2} = (0.47368\,\text{A})/\sqrt{2} = \boxed{0.33\,\text{A}}$$

51. (*a*) When everything electrical is turned off, no current will be flowing into the house, even though a voltage is being supplied. Since for a given voltage, the more resistance, the lower the current, a zero current corresponds to an infinite resistance.

(*b*) Use Eq. 25-7a to calculate the resistance.

$$P = \frac{V^2}{R} \quad \rightarrow \quad R = \frac{V^2}{P} = \frac{(120\,\text{V})^2}{2(75\,\text{W})} = \boxed{96\,\Omega}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

52. The power and current can be used to find the peak voltage, and then the rms voltage can be found from the peak voltage.

$$\overline{P} = I_{\text{rms}} V_{\text{rms}} = \frac{I_{\text{peak}}}{\sqrt{2}} V_{\text{rms}} \quad \rightarrow \quad V_{\text{rms}} = \frac{\sqrt{2}\,\overline{P}}{I_{\text{peak}}} = \frac{\sqrt{2}\,(1500\,\text{W})}{5.4\,\text{A}} = \boxed{390\,\text{V}}$$

53. Use the average power and rms voltage to calculate the peak voltage and peak current.

(*a*) $V_{\text{peak}} = \sqrt{2} V_{\text{rms}} = \sqrt{2}\,(660\,\text{V}) = 933.4\,\text{V} \approx \boxed{930\,\text{V}}$

(*b*) $\overline{P} = I_{\text{rms}} V_{\text{rms}} = \frac{I_{\text{peak}}}{\sqrt{2}} V_{\text{rms}} \quad \rightarrow \quad I_{\text{peak}} = \frac{\sqrt{2}\,\overline{P}}{V_{\text{rms}}} = \frac{\sqrt{2}\,(1800\,\text{W})}{660\,\text{V}} = \boxed{3.9\,\text{A}}$

54. (*a*) We assume that the 2.5 hp is the average power, so the maximum power is twice that, or 5.0 hp, as seen in Figure 25-22.

$$5.0\,\text{hp}\left(\frac{746\,\text{W}}{1\,\text{hp}}\right) = 3730\,\text{W} \approx \boxed{3700\,\text{W}}$$

(*b*) Use the average power and the rms voltage to find the peak current.

$$\overline{P} = I_{\text{rms}} V_{\text{rms}} = \frac{I_{\text{peak}}}{\sqrt{2}} V_{\text{rms}} \quad \rightarrow \quad I_{\text{peak}} = \frac{\sqrt{2}\,\overline{P}}{V_{\text{rms}}} = \frac{\sqrt{2}\left[\frac{1}{2}(3730\,\text{W})\right]}{240\,\text{V}} = \boxed{11\,\text{A}}$$

55. (*a*) The average power used can be found from the resistance and the rms voltage by Eq. 25-10c.

$$\overline{P} = \frac{V_{\text{rms}}^2}{R} = \frac{(240\,\text{V})^2}{44\,\Omega} = 1309\,\text{W} \approx \boxed{1300\,\text{W}}$$

(*b*) The maximum power is twice the average power, and the minimum power is 0.

$$P_{\text{max}} = 2\overline{P} = 2(1309\,\text{W}) \approx \boxed{2600\,\text{W}} \qquad P_{\text{min}} = \boxed{0\,\text{W}}$$

56. (*a*) Find V_{rms}. Use an integral from Appendix B-4, page A-7.

$$V_{\text{rms}} = \left[\frac{1}{T}\int_0^T \left(V_0 \sin\frac{2\pi t}{T}\right)^2 dt\right]^{1/2} = \left[\frac{V_0^2}{T}\left(\frac{t}{2} - \frac{\sin\left(\frac{4\pi t}{T}\right)}{\frac{8\pi}{T}}\right)_0^T\right]^{1/2} = \left(\frac{V_0^2}{2}\right)^{1/2} = \boxed{\frac{V_0}{\sqrt{2}}}$$

(*b*) Find V_{rms}.

$$V_{\text{rms}} = \left[\frac{1}{T}\int_0^T V^2 dt\right]^{1/2} = \left[\frac{1}{T}\int_0^{T/2} V_0^2 dt + \frac{1}{T}\int_{T/2}^T (0)^2\, dt\right]^{1/2} = \left[\frac{V_0^2}{T}\frac{T}{2} + 0\right]^{1/2} = \boxed{\frac{V_0}{\sqrt{2}}}$$

57. (*a*) We follow the derivation in Example 25-14. Start with Eq. 25-14, in absolute value.

$$j = nev_{\text{d}} \quad \rightarrow \quad v_{\text{d}} = \frac{j}{ne} = \frac{I}{neA} = \frac{I}{\left(\frac{N(1\,\text{mole})}{m(1\,\text{mole})}\rho_{\text{D}}\right) e\left[\pi\left(\frac{1}{2}d\right)^2\right]} = \frac{4Im}{N\rho_{\text{D}} e\pi d^2}$$

$$v_{\text{d}} = \frac{4\left(2.3\times10^{-6}\,\text{A}\right)\left(63.5\times10^{-3}\,\text{kg}\right)}{\left(6.02\times10^{23}\right)\left(8.9\times10^{3}\,\text{kg/m}^3\right)\left(1.60\times10^{-19}\,\text{C}\right)\pi\left(0.65\times10^{-3}\,\text{m}\right)^2} = \boxed{5.1\times10^{-10}\,\text{m/s}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Calculate the current density from Eq. 25-11.

$$j = \frac{I}{A} = \frac{I}{\pi r^2} = \frac{4I}{\pi d^2} = \frac{4\left(2.3\times10^{-6}\,\text{A}\right)}{\pi\left(6.5\times10^{-4}\,\text{m}\right)^2} = 6.931\,\text{A/m}^2 \approx \boxed{6.9\,\text{A/m}^2}$$

(*c*) The electric field is calculated from Eq. 25-17.

$$j = \frac{1}{\rho}E \;\rightarrow\; E = \rho j = \left(1.68\times10^{-8}\,\Omega\bullet\text{m}\right)\left(6.931\,\text{A/m}^2\right) = \boxed{1.2\times10^{-7}\,\text{V/m}}$$

58. (*a*) Use Ohm's law to find the resistance.

$$V = IR \;\rightarrow\; R = \frac{V}{I} = \frac{0.0220\,\text{V}}{0.75\,\text{A}} = 0.02933\,\Omega \approx \boxed{0.029\,\Omega}$$

(*b*) Find the resistivity from Eq. 25-3.

$$R = \frac{\rho\ell}{A} \;\rightarrow$$

$$\rho = \frac{RA}{\ell} = \frac{R\pi r^2}{\ell} = \frac{\left(0.02933\,\Omega\right)\pi\left(1.0\times10^{-3}\,\text{m}\right)^2}{\left(5.80\,\text{m}\right)} = 1.589\times10^{-8}\,\Omega\bullet\text{m} \approx \boxed{1.6\times10^{-8}\,\Omega\bullet\text{m}}$$

(*c*) Use Eq. 25-11 to find the current density.

$$j = \frac{I}{A} = \frac{I}{\pi r^2} = \frac{0.75}{\pi\left(0.0010\,\text{m}\right)^2} = 2.387\times10^5\,\text{A/m}^2 \approx \boxed{2.4\times10^5\,\text{A/m}^2}$$

(*d*) Use Eq. 25-17 to find the electric field.

$$j = \frac{1}{\rho}E \;\rightarrow$$

$$E = \rho j = \left(1.589\times10^{-8}\,\Omega\bullet\text{m}\right)\left(2.387\times10^5\,\text{A/m}^2\right) = 3.793\times10^{-3}\,\text{V/m} \approx \boxed{3.8\times10^{-3}\,\text{V/m}}$$

(*e*) Find the number of electrons per unit volume from the absolute value of Eq. 25-14.

$$j = nev_\text{d} \;\rightarrow\; n = \frac{j}{v_\text{d}e} = \frac{2.387\times10^5\,\text{A/m}^2}{\left(1.7\times10^{-5}\,\text{m/s}\right)\left(1.60\times10^{-19}\,\text{C}\right)} = \boxed{8.8\times10^{28}\,\text{e}^-\text{/m}^3}$$

59. We are given a charge density and a speed (like the drift speed) for both types of ions. From that we can use Eq. 25-13 (without the negative sign) to determine the current per unit area. Both currents are in the same direction in terms of conventional current – positive charge moving north has the same effect as negative charge moving south – and so they can be added.

$$I = neAv_\text{d} \;\rightarrow$$

$$\frac{I}{A} = \left(nev_\text{d}\right)_\text{He} + \left(nev_\text{d}\right)_\text{O} = \left[\left(2.8\times10^{12}\,\text{ions/m}^3\right)2\left(1.60\times10^{-19}\,\text{C/ion}\right)\left(2.0\times10^6\,\text{m/s}\right)\right] +$$
$$\left[\left(7.0\times10^{11}\,\text{ions/m}^3\right)\left(1.60\times10^{-19}\,\text{C/ion}\right)\left(6.2\times10^6\,\text{m/s}\right)\right]$$

$$= 2.486\,\text{A/m}^2 \approx \boxed{2.5\,\text{A/m}^2\text{, North}}$$

60. The magnitude of the electric field is the voltage change per unit meter.

$$\left|E\right| = \frac{\Delta V}{\Delta x} = \frac{70\times10^{-3}\,\text{V}}{1.0\times10^{-8}\,\text{m}} = \boxed{7.0\times10^6\,\text{V/m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

61. The speed is the change in position per unit time.

$$v = \frac{\Delta x}{\Delta t} = \frac{7.20\times10^{-2}\,\text{m} - 3.40\times10^{-2}\,\text{m}}{0.0063\,\text{s} - 0.0052\,\text{s}} = \boxed{35\,\text{m/s}}$$

Two measurements are needed because there may be a time delay from the stimulation of the nerve to the generation of the action potential.

62. The power is the work done per unit time. The work done to move a charge through a potential difference is the charge times the potential difference. The charge density must be multiplied by the surface area of the cell (the surface area of an open tube, length times circumference) to find the actual charge moved.

$$P = \frac{W}{t} = \frac{QV}{t} = \frac{Q}{t}V$$

$$= \left(3\times10^{-7}\,\frac{\text{mol}}{\text{m}^2\bullet\text{s}}\right)\left(6.02\times10^{23}\,\frac{\text{ions}}{\text{mol}}\right)\left(1.6\times10^{-19}\,\frac{\text{C}}{\text{ion}}\right)(0.10\,\text{m})\,\pi\left(20\times10^{-6}\,\text{m}\right)(0.030\,\text{V})$$

$$= \boxed{5.4\times10^{-9}\,\text{W}}$$

63. The energy supplied by the battery is the energy consumed by the lights.

$$E_{\text{supplied}} = E_{\text{consumed}} \;\rightarrow\; Q\Delta V = Pt \;\rightarrow$$

$$t = \frac{Q\Delta V}{P} = \frac{(85\text{A}\bullet\text{h})(3600\,\text{s/h})(12\,\text{V})}{92\,\text{W}} = 39913\,\text{s}\left(\frac{1\,\text{h}}{3600\,\text{s}}\right) = 11.09\,\text{h} \approx \boxed{11\,\text{h}}$$

64. The ampere-hour is a unit of charge.

$$(1.00\text{A}\bullet\text{h})\left(\frac{1\,\text{C/s}}{1\,\text{A}}\right)\left(\frac{3600\,\text{s}}{1\,\text{h}}\right) = \boxed{3600\,\text{C}}$$

65. Use Eqs. 25-3 and 25-7b.

$$R = \rho\frac{\ell}{A} = \rho\frac{\ell}{\pi r^2} = \frac{4\rho\ell}{\pi d^2} \;\;;\; P = \frac{V^2}{R} = \frac{V^2}{\dfrac{4\rho\ell}{\pi d^2}} \;\rightarrow$$

$$\ell = \frac{V^2\pi d^2}{4\rho P} = \frac{(1.5\,\text{V})^2\,\pi\left(5.0\times10^{-4}\,\text{m}\right)^2}{4\left(1.68\times10^{-8}\,\Omega\bullet\text{m}\right)(15\,\text{W})} = 1.753\,\text{m} \approx \boxed{1.8\,\text{m}}$$

If the voltage increases by a factor of 6 without the resistance changing, the power will increase by a factor of 36. The blanket would theoretically be able to deliver 540 W of power, which might make the material catch on fire or burn the occupant.

66. Use Eq. 25-6 to calculate the current.

$$P = IV \;\rightarrow\; I = \frac{P}{V} = \frac{746\,\text{W}}{120\,\text{V}} = \boxed{6.22\,\text{A}}$$

67. From Eq. 25-2b, if $R = V/I$, then $G = I/V$

$$G = \frac{I}{V} = \frac{0.48\,\text{A}}{3.0\,\text{V}} = \boxed{0.16\,\text{S}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

68. Use Eq. 25-7b to express the resistance in terms of the power, and Eq. 25-3 to express the resistance in terms of the wire geometry.

$$P = \frac{V^2}{R} \quad \rightarrow \quad R = \frac{V^2}{P} \qquad R = \rho\frac{\ell}{A} = \rho\frac{\ell}{\pi r^2} = 4\rho\frac{\ell}{\pi d^2}$$

$$4\rho\frac{\ell}{\pi d^2} = \frac{V^2}{P} \quad \rightarrow \quad d = \sqrt{\frac{4\rho\ell P}{\pi V^2}} = \sqrt{\frac{4\left(9.71\times10^{-8}\,\Omega\cdot\text{m}\right)\left(3.5\,\text{m}\right)\left(1500\,\text{W}\right)}{\pi\left(110\,\text{V}\right)^2}} = \boxed{2.3\times10^{-4}\,\text{m}}$$

69. (*a*) Calculate the total kWh used per day, and then multiply by the number of days and the cost per kWh.

$$\left(1.8\,\text{kW}\right)\left(2.0\,\text{h/d}\right) + 4\left(0.1\,\text{kW}\right)\left(6.0\,\text{h/d}\right) + \left(3.0\,\text{kW}\right)\left(1.0\,\text{h/d}\right) + \left(2.0\,\text{kWh/d}\right)$$

$$= 11.0\,\text{kWh/d}$$

$$\text{Cost} = \left(11.0\,\text{kWh/d}\right)\left(30\,\text{d}\right)\left(\frac{\$0.105}{\text{kWh}}\right) = \$34.65 \approx \boxed{\$35 \text{ per month}}$$

(*b*) The energy required by the household is 35% of the energy that needs to be supplied by the power plant.

$$\text{Household Energy} = 0.35\left(\text{coal mass}\right)\left(\text{coal energy per mass}\right) \quad \rightarrow$$

$$\text{coal mass} = \frac{\text{Household Energy}}{\left(0.35\right)\left(\text{coal energy per mass}\right)} = \frac{\left(11.0\,\text{kWh/d}\right)\left(365\,\text{d}\right)\left(\frac{1000\,\text{W}}{\text{kW}}\right)\left(\frac{3600\,\text{s}}{1\,\text{h}}\right)}{\left(0.35\right)\left(7500\frac{\text{kcal}}{\text{kg}}\right)\left(\frac{4186\,\text{J}}{1\,\text{kcal}}\right)}$$

$$= 1315\,\text{kg} \approx \boxed{1300\,\text{kg of coal}}$$

70. To deliver 15 MW of power at 120 V requires a current of $I = \frac{P}{V} = \frac{15\times10^6\,\text{W}}{120\,\text{V}} = 1.25\times10^5\,\text{A}$.

Calculate the power dissipated in the resistors using the current and the resistance.

$$P = I^2R = I^2\rho\frac{L}{A} = I^2\rho\frac{L}{\pi r^2} = 4I^2\rho\frac{L}{\pi d^2} = 4\left(1.25\times10^5\,\text{A}\right)^2\left(1.68\times10^{-8}\,\Omega\cdot\text{m}\right)\frac{2\left(1.0\,\text{m}\right)}{\pi\left(5.0\times10^{-3}\,\text{m}\right)^2}$$

$$= 2.674\times10^7\,\text{W}$$

$$\text{Cost} = \left(\text{Power}\right)\left(\text{time}\right)\left(\text{rate per kWh}\right) = \left(2.674\times10^7\,\text{W}\right)\left(\frac{1\,\text{kW}}{1000\,\text{W}}\right)\left(1\,\text{h}\right)\left(\frac{\$0.090}{\text{kWh}}\right)$$

$$= \$2407 \approx \boxed{\$2,400 \text{ per hour per meter}}$$

71. (*a*) Use Eq. 25-7b to relate the power to the voltage for a constant resistance.

$$P = \frac{V^2}{R} \quad \rightarrow \quad \frac{P_{105}}{P_{117}} = \frac{\left(105\,\text{V}\right)^2/R}{\left(117\,\text{V}\right)^2/R} = \frac{\left(105\,\text{V}\right)^2}{\left(117\,\text{V}\right)^2} = 0.805 \text{ or a } \boxed{19.5\% \text{ decrease}}$$

(*b*) The lower power output means that the resistor is generating less heat, and so the resistor's temperature would be lower. The lower temperature results in a lower value of the resistance, which would increase the power output at the lower voltages. Thus the decrease would be smaller than the value given in the first part of the problem.

72. Assume that we have a meter of wire, carrying 35 A of current, and dissipating 1.5 W of heat. The power dissipated is $P_R = I^2R$, and the resistance is $R = \dfrac{\rho\ell}{A}$.

$$P_R = I^2R = I^2\frac{\rho\ell}{A} = I^2\frac{\rho\ell}{\pi r^2} = I^2\frac{4\rho\ell}{\pi d^2} \quad \rightarrow$$

$$d = \sqrt{I^2\frac{4\rho\ell}{P_R\pi}} = 2I\sqrt{\frac{\rho\ell}{P_R\pi}} = 2(35\,\text{A})\sqrt{\frac{(1.68\times10^{-8}\,\Omega\cdot\text{m})(1.0\,\text{m})}{(1.5\,\text{W})\pi}} = \boxed{4.2\times10^{-3}\,\text{m}}$$

73. (*a*) The resistance at the operating temperature can be calculated directly from Eq. 25-7.

$$P = \frac{V^2}{R} \quad \rightarrow \quad R = \frac{V^2}{P} = \frac{(120\,\text{V})^2}{75\,\text{W}} = \boxed{190\,\Omega}$$

(*b*) The resistance at room temperature is found by converting Eq. 25-5 into an equation for resistances and solving for R_0.

$$R = R_0\left[1+\alpha\left(T-T_0\right)\right]$$

$$R_0 = \frac{R}{\left[1+\alpha\left(T-T_0\right)\right]} = \frac{192\,\Omega}{\left[1+(0.0045\,\text{K}^{-1})(3000\,\text{K}-293\,\text{K})\right]} = \boxed{15\,\Omega}$$

74. (*a*) The angular frequency is $\omega = 210\,\text{rad/s}$.

$$f = \frac{\omega}{2\pi} = \frac{210\,\text{rad/s}}{2\pi} = 33.42\,\text{Hz} \approx \boxed{33\,\text{Hz}}$$

(*b*) The maximum current is 1.80 A.

$$I_{\text{rms}} = \frac{I_{\text{max}}}{\sqrt{2}} = \frac{1.80\,\text{A}}{\sqrt{2}} = \boxed{1.27\,\text{A}}$$

(*c*) For a resistor, $V = IR$.

$$V = IR = (1.80\,\text{A})(\sin 210t)(24.0\,\Omega) = \boxed{(43.2\sin 210t)\,\text{V}}$$

75. (*a*) The power delivered to the interior is 65% of the power drawn from the source.

$$P_{\text{interior}} = 0.65P_{\text{source}} \quad \rightarrow \quad P_{\text{source}} = \frac{P_{\text{interior}}}{0.65} = \frac{950\,\text{W}}{0.65} = 1462\,\text{W} \approx \boxed{1500\,\text{W}}$$

(*b*) The current drawn is current from the source, and so the source power is used to calculate the current.

$$P_{\text{source}} = IV_{\text{source}} \quad \rightarrow \quad I = \frac{P_{\text{source}}}{V_{\text{source}}} = \frac{1462\,\text{W}}{120\,\text{V}} = 12.18\,\text{A} \approx \boxed{12\,\text{A}}$$

76. The volume of wire is unchanged by the stretching. The volume is equal to the length of the wire times its cross-sectional area, and since the length was increased by a factor of 1.20, the area was decreased by a factor of 1.20. Use Eq. 25-3.

$$R_0 = \rho\frac{\ell_0}{A_0} \qquad \ell = 1.20\ell_0 \qquad A = \frac{A_0}{1.20} \qquad R = \rho\frac{\ell}{A} = \rho\frac{1.20\ell_0}{\frac{A_0}{1.20}} = (1.20)^2\rho\frac{\ell_0}{A_0} = 1.44R_0 = \boxed{1.44\,\Omega}$$

77. The long, thick conductor is labeled as conductor number 1, and the short, thin conductor is labeled as number 2. The power transformed by a resistor is given by Eq. 25-7b, $P = V^2/R$, and both have the same voltage applied.

$$R_1 = \rho\frac{\ell_1}{A_1} \quad R_2 = \rho\frac{\ell_2}{A_2} \quad \ell_1 = 2\ell_2 \quad A_1 = 4A_2 \quad (\text{diameter}_1 = 2\text{diameter}_2)$$

$$\frac{P_1}{P_2} = \frac{V_1^2/R_1}{V_2^2/R_2} = \frac{R_2}{R_1} = \frac{\rho\ell_2/A_2}{\rho\ell_1/A_1} = \frac{\ell_2}{\ell_1}\frac{A_1}{A_2} = \frac{1}{2}\times 4 = 2 \qquad \boxed{P_1 : P_2 = 2:1}$$

78. The heater must heat $108\,\text{m}^3$ of air per hour from 5°C to 20°C, and also replace the heat being lost at a rate of 850 kcal/h. Use Eq. 19-2 to calculate the energy needed to heat the air. The density of air is found in Table 13-1.

$$Q = mc\Delta T \;\rightarrow\; \frac{Q}{t} = \frac{m}{t}c\Delta T = \left(108\frac{\text{m}^3}{\text{h}}\right)\left(1.29\frac{\text{kg}}{\text{m}^3}\right)\left(0.17\frac{\text{kcal}}{\text{kg}\bullet\text{C}^\circ}\right)(15\text{C}^\circ) = 355\frac{\text{kcal}}{\text{h}}$$

$$\text{Power required} = 355\frac{\text{kcal}}{\text{h}} + 850\frac{\text{kcal}}{\text{h}} = 1205\frac{\text{kcal}}{\text{h}}\left(\frac{4186\,\text{J}}{\text{kcal}}\right)\left(\frac{1\text{h}}{3600\,\text{s}}\right) = 1401\,\text{W} \approx \boxed{1400\,\text{W}}$$

79. (*a*) Use Eq. 25-7b.

$$P = \frac{V^2}{R} \;\rightarrow\; R = \frac{V^2}{P} = \frac{(240\,\text{V})^2}{2800\,\text{W}} = 20.57\,\Omega \approx \boxed{21\Omega}$$

(*b*) Only 75% of the heat from the oven is used to heat the water. Use Eq. 19-2.

$0.75(P_{\text{oven}})t$ = Heat absorbed by water = $mc\Delta T \;\rightarrow$

$$t = \frac{mc\Delta T}{0.75(P_{\text{oven}})} = \frac{(0.120\,\text{L})\left(\frac{1\text{kg}}{1\text{L}}\right)(4186\,\text{J/kg}\bullet\text{C}^\circ)(85\text{C}^\circ)}{0.75(2800\,\text{W})} = 20.33\,\text{s} \approx \boxed{20\,\text{s}}\,(2\text{ sig. fig.})$$

(*c*) $\dfrac{11\,\text{cents}}{\text{kWh}}(2.8\,\text{kW})(20.33\,\text{s})\dfrac{1\text{h}}{3600\,\text{s}} = \boxed{0.17\,\text{cents}}$

80. (*a*) The horsepower required is the power dissipated by the frictional force, since we are neglecting the energy used for acceleration.

$$P = Fv = (240\,\text{N})(45\,\text{km/hr})\left(\frac{1\,\text{m/s}}{3.6\,\text{km/hr}}\right) = 3000\,\text{W}\left(\frac{1\,\text{hp}}{746\,\text{W}}\right) = \boxed{4.0\,\text{hp}}$$

(*b*) The charge available by each battery is $Q = 95\text{A}\bullet\text{h} = 95\,\text{C/s}\bullet 3600\,\text{s} = 3.42\times10^5\,\text{C}$, and so the total charge available is 24 times that. The potential energy of that charge is the charge times the voltage. That energy must be delivered (batteries discharged) in a certain amount of time to produce the 3000 W necessary. The speed of the car times the discharge time is the range of the car between recharges.

$$P = \frac{U}{t} = \frac{QV}{t} \;\rightarrow\; t = \frac{QV}{P} = \frac{d}{v} \;\rightarrow$$

$$d = vt = v\frac{QV}{P} = v\frac{QV}{Fv} = \frac{QV}{F} = \frac{24\left(3.42\times10^5\,\text{C}\right)(12\,\text{V})}{240\,\text{N}} = \boxed{410\,\text{km}}$$

81. The mass of the wire is the density of copper times the volume of the wire, and the resistance of the wire is given by Eq. 25-3. We represent the mass density by ρ_m and the resistivity by ρ.

$$R = \rho\frac{\ell}{A} \rightarrow A = \frac{\rho\ell}{R} \qquad m = \rho_m \ell A = \rho_m \ell \frac{\rho\ell}{R} \rightarrow$$

$$\ell = \sqrt{\frac{mR}{\rho_m \rho}} = \sqrt{\frac{(0.0155\,\text{kg})(12.5\,\Omega)}{(8.9\times10^3\,\text{kg/m}^3)(1.68\times10^{-8}\,\Omega\cdot\text{m})}} = 35.997\,\text{m} \approx \boxed{36.0\,\text{m}}$$

$$A = \frac{\rho\ell}{R} = \pi\left(\tfrac{1}{2}d\right)^2 \rightarrow d = \sqrt{\frac{4\rho\ell}{\pi R}} = \sqrt{\frac{4(1.68\times10^{-8}\,\Omega\cdot\text{m})(35.997\,\text{m})}{\pi(12.5\,\Omega)}} = \boxed{2.48\times10^{-4}\,\text{m}}$$

82. The resistance can be calculated from the power and voltage, and then the diameter of the wire can be calculated from the resistance.

$$P = \frac{V^2}{R} \rightarrow R = \frac{V^2}{P} \qquad R = \frac{\rho L}{A} = \frac{\rho L}{\pi\left(\tfrac{1}{2}d\right)^2} \rightarrow \frac{V^2}{P} = \frac{\rho L}{\pi\left(\tfrac{1}{2}d\right)^2} \rightarrow$$

$$d = \sqrt{\frac{4\rho LP}{\pi V^2}} = \sqrt{\frac{4(100\times10^{-8}\,\Omega\cdot\text{m})(3.8\,\text{m})(95\,\text{W})}{\pi(120\,\text{V})^2}} = 1.787\times10^{-4}\,\text{m} \approx \boxed{1.8\times10^{-4}\,\text{m}}$$

83. Use Eq. 25-7b.

(*a*) $P = \dfrac{V^2}{R} = \dfrac{(120\,\text{V})^2}{12\,\Omega} = \boxed{1200\,\text{W}}$

(*b*) $P = \dfrac{V^2}{R} = \dfrac{(120\,\text{V})^2}{140\,\Omega} = 103\,\text{W} \approx \boxed{100\,\text{W}}$ (2 sig. fig.)

84. Use Eq. 25-7b for the power in each case, assuming the resistance is constant.

$$\frac{P_{13.8\,\text{V}}}{P_{12.0\,\text{V}}} = \frac{\left(V^2/R\right)_{13.8\,\text{V}}}{\left(V^2/R\right)_{12.0\,\text{V}}} = \frac{13.8^2}{12.0^2} = 1.3225 = \boxed{32\%\text{ increase}}$$

85. Model the protons as moving in a continuous beam of cross-sectional area *A*. Then by Eq. 25-13, $I = neAv_d$, where we only consider the absolute value of the current. The variable *n* is the number of protons per unit volume, so $n = \dfrac{N}{A\ell}$, where *N* is the number of protons in the beam and ℓ is the circumference of the ring. The "drift" velocity in this case is the speed of light.

$$I = neAv_d = \frac{N}{A\ell}eAv_d = \frac{N}{\ell}ev_d \rightarrow$$

$$N = \frac{I\ell}{ev_d} = \frac{(11\times10^{-3})(6300\,\text{m})}{(1.60\times10^{-19}\,\text{C})(3.00\times10^8\,\text{m/s})} = \boxed{1.4\times10^{12}\,\text{protons}}$$

86. (*a*) The current can be found from Eq. 25-6.

$$I = P/V \qquad I_A = P_A/V_A = 40\text{W}/120\,\text{V} = \boxed{0.33\,\text{A}} \qquad I_B = P_B/V_B = 40\text{W}/12\,\text{V} = \boxed{3.3\,\text{A}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The resistance can be found from Eq. 25-7b.

$$R = \frac{V^2}{P} \qquad R_A = \frac{V_A^2}{P_A} = \frac{(120\,\text{V})^2}{40\,\text{W}} = \boxed{360\,\Omega} \qquad R_B = \frac{V_B^2}{P_B} = \frac{(12\,\text{V})^2}{40\,\text{W}} = \boxed{3.6\,\Omega}$$

(*c*) The charge is the current times the time.

$$Q = It \qquad Q_A = I_A t = (0.33\,\text{A})(3600\,\text{s}) = \boxed{1200\,\text{C}}$$

$$Q_B = I_B t = (3.3\,\text{A})(3600\,\text{s}) = \boxed{12{,}000\,\text{C}}$$

(*d*) The energy is the power times the time, and the power is the same for both bulbs.

$$E = Pt \qquad E_A = E_B = (40\,\text{W})(3600\,\text{s}) = \boxed{1.4\times10^5\,\text{J}}$$

(*e*) Bulb B requires a larger current, and so should have larger diameter connecting wires to avoid overheating the connecting wires.

87. (*a*) The power is given by $P = IV$.

$$P = IV = (14\,\text{A})(220\,\text{V}) = 3080\,\text{W} \approx \boxed{3100\,\text{W}}$$

(*b*) The power dissipated is given by $P_R = I^2R$, and the resistance is $R = \dfrac{\rho\ell}{A}$.

$$P_R = I^2R = I^2\frac{\rho\ell}{A} = I^2\frac{\rho\ell}{\pi r^2} = I^2\frac{4\rho\ell}{\pi d^2} = (14\,\text{A})^2\frac{4\left(1.68\times10^{-8}\,\Omega\cdot\text{m}\right)(15\,\text{m})}{\pi\left(1.628\times10^{-3}\,\text{m}\right)^2} = 23.73\,\text{W}$$

$$\approx \boxed{24\,\text{W}}$$

(*c*) $$P_R = I^2\frac{4\rho L}{\pi d^2} = (14\,\text{A})^2\frac{4\left(1.68\times10^{-8}\,\Omega\cdot\text{m}\right)(15\,\text{m})}{\pi\left(2.053\times10^{-3}\,\text{m}\right)^2} = 14.92\,\text{W} \approx \boxed{15\,\text{W}}$$

(*d*) The savings is due to the power difference.

$$\text{Savings} = (23.73\,\text{W} - 14.92\,\text{W})\left(\frac{1\,\text{kW}}{1000\,\text{W}}\right)(30\,\text{d})\left(\frac{12\,\text{h}}{1\,\text{d}}\right)\left(\frac{\$0.12}{1\,\text{kWh}}\right)$$

$$= \$0.3806/\text{month} \approx \boxed{38\,\text{cents per month}}$$

88. The wasted power is due to losses in the wire. The current in the wire can be found by $I = P/V$.

(*a*) $$P_R = I^2R = \frac{P^2}{V^2}R = \frac{P^2}{V^2}\frac{\rho L}{A} = \frac{P^2}{V^2}\frac{\rho L}{\pi r^2} = \frac{P^2}{V^2}\frac{4\rho L}{\pi d^2}$$

$$= \frac{(1750\,\text{W})^2}{(120\,\text{V})^2}\frac{4\left(1.68\times10^{-8}\,\Omega\cdot\text{m}\right)(25.0\,\text{m})}{\pi\left(2.59\times10^{-3}\,\text{m}\right)^2} = 16.954\,\text{W} \approx \boxed{17.0\,\text{W}}$$

(*b*) $$P_R = \frac{P^2}{V^2}\frac{4\rho L}{\pi d^2} = \frac{(1750\,\text{W})^2}{(120\,\text{V})^2}\frac{4\left(1.68\times10^{-8}\,\Omega\cdot\text{m}\right)(25.0\,\text{m})}{\pi\left(4.12\times10^{-3}\,\text{m}\right)^2} = \boxed{6.70\,\text{W}}$$

89. (*a*) The D-cell provides 25 mA at 1.5 V for 820 h, at a cost of $1.70.

$$\text{Energy} = Pt = VIt = (1.5\,\text{V})(0.025\,\text{A})(820\,\text{h})\left(\frac{1\,\text{kW}}{1000\,\text{W}}\right) = 0.03075\,\text{kWh}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\text{Cost/kWh} = \frac{\$1.70}{0.03075\,\text{kWh}} = \$55.28/\text{kWh} \approx \boxed{\$55/\text{kWh}}$$

(*b*) The AA-cell provides 25 mA at 1.5 V for 120 h, at a cost of $1.25.

$$\text{Energy} = Pt = VIt = (1.5\,\text{V})(0.025\,\text{A})(120\,\text{h})\left(\frac{1\,\text{kW}}{1000\,\text{W}}\right) = 0.0045\,\text{kWh}$$

$$\text{Cost/kWh} = \frac{\$1.25}{0.0045\,\text{kWh}} = \$277.78/\text{kWh} \approx \boxed{\$280/\text{kWh}}$$

The D-cell is $\dfrac{\$55.28/\text{kWh}}{\$0.10/\text{kWh}} \approx \boxed{550\times\text{as costly}}$. The AA-cell is $\dfrac{\$277.78/\text{kWh}}{\$0.10/\text{kWh}} \approx \boxed{2800\times\text{as costly}}$.

90. The electrons are assumed to be moving with simple harmonic motion. During one cycle, an object in simple harmonic motion will move a distance equal to the amplitude from its equilibrium point. From Eq. 14-9a, we know that $v_{\max} = A\omega$, where ω is the angular frequency of oscillation. From Eq. 25-13 in absolute value, we see that $I_{\max} = neAv_{\max}$. Finally, the maximum current can be related to the power by Eqs. 25-9 and 25-10. The charge carrier density, *n*, is calculated in Example 25-14.

$$\overline{P} = I_{\text{rms}}V_{\text{rms}} = \tfrac{1}{\sqrt{2}}I_{\max}V_{\text{rms}}$$

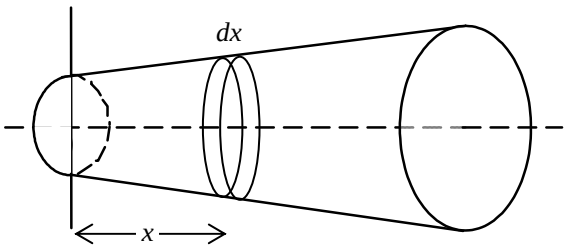
$$A = \frac{v_{\max}}{\omega} = \frac{I_{\max}}{\omega neA} = \frac{\sqrt{2}\overline{P}}{\omega ne\dfrac{\pi d^2}{4}V_{\text{rms}}}$$

$$= \frac{4\sqrt{2}\,(550\,\text{W})}{2\pi\,(60\,\text{Hz})\left(8.4\times10^{28}\,\text{m}^{-3}\right)\left(1.60\times10^{-19}\,\text{C}\right)\pi\left(1.7\times10^{-3}\,\text{m}\right)^2(120\,\text{V})} = \boxed{5.6\times10^{-7}\,\text{m}}$$

The electron will move this distance in both directions from its equilibrium point.

91. Eq. 25-3 can be used. The area to be used is the cross-sectional area of the pipe.

$$R = \frac{\rho\ell}{A} = \frac{\rho\ell}{\pi\left(r_{\text{outside}}^2 - r_{\text{inside}}^2\right)} = \frac{\left(1.68\times10^{-8}\,\Omega\cdot\text{m}\right)(10.0\,\text{m})}{\pi\left[\left(2.50\times10^{-2}\,\text{m}\right)^2 - \left(1.50\times10^{-2}\,\text{m}\right)^2\right]} = \boxed{1.34\times10^{-4}\,\Omega}$$



92. We assume that all of the current that enters at *a* leaves at *b*, so that the current is the same at each end. The current density is given by Eq. 25-11.

$$j_{\text{a}} = \frac{I}{A_{\text{a}}} = \frac{I}{\pi\left(\frac{1}{2}a\right)^2} = \frac{4I}{\pi a^2} = \frac{4(2.0\,\text{A})}{\pi\left(2.5\times10^{-3}\,\text{m}\right)^2} = \boxed{4.1\times10^5\,\text{A/m}^2}$$

$$j_{\text{b}} = \frac{I}{A_{\text{b}}} = \frac{I}{\pi\left(\frac{1}{2}b\right)^2} = \frac{4I}{\pi b^2} = \frac{4(2.0\,\text{A})}{\pi\left(4.0\times10^{-3}\,\text{m}\right)^2} = \boxed{1.6\times10^5\,\text{A/m}^2}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

93. Using Eq. 25-3, we find the infinitesimal resistance first of a thin vertical slice at a horizontal distance *x* from the center of the left side towards the center of the right side. Let the thickness of that slice be *dx*. That thickness corresponds to the variable ℓ in Eq. 25-3. The diameter of this slice is $a + \frac{x}{\ell}(b-a)$. Then integrate over all the slices to find the total resistance.

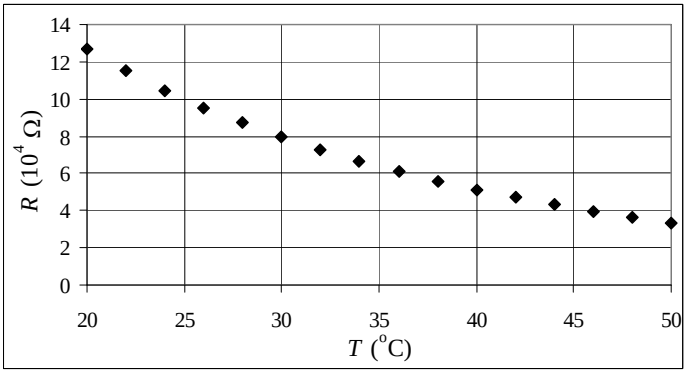
$$R = \rho\frac{\ell}{A} \quad \rightarrow \quad dR = \rho\frac{dx}{\pi\frac{1}{4}\left(a + \frac{x}{\ell}(b-a)\right)^2} \quad \rightarrow$$

$$R = \int dR = \int_0^{\ell} \rho\frac{dx}{\pi\frac{1}{4}\left(a + \frac{x}{\ell}(b-a)\right)^2} = -\frac{4\rho}{\pi}\frac{\ell}{b-a}\frac{1}{\left(a + \frac{x}{\ell}(b-a)\right)}\Bigg|_0^{\ell} = \boxed{\frac{4\rho}{\pi}\frac{\ell}{ab}}$$

94. The resistance of the filament when the flashlight is on is $R = \frac{V}{I} = \frac{3.2\,\text{V}}{0.20\,\text{A}} = 16\,\Omega$. That can be used with a combination of Eqs. 25-3 and 25-5 to find the temperature.

$$R = R_0\left[1 + \alpha\left(T - T_0\right)\right] \quad \rightarrow$$

$$T = T_0 + \frac{1}{\alpha}\left(\frac{R}{R_0} - 1\right) = 20^\circ\text{C} + \frac{1}{0.0045\left(\text{C}^\circ\right)^{-1}}\left(\frac{16\,\Omega}{1.5\,\Omega} - 1\right) = 2168^\circ\text{C} \approx \boxed{2200^\circ\text{C}}$$



95. When the tank is empty, the entire length of the wire is in a non-superconducting state, and so has a non-zero resistivity, which we call ρ. Then the resistance of the wire when the tank is empty is given by $R_0 = \rho\frac{\ell}{A} = \frac{V_0}{I}$. When a length *x* of the wire is superconducting, that portion of the wire has 0 resistance. Then the resistance of the wire is only due to the length $\ell - x$, and so $R = \rho\frac{\ell - x}{A} = \rho\frac{\ell}{A}\frac{\ell - x}{\ell} = R_0\frac{\ell - x}{\ell}$. This resistance, combined with the constant current, gives $V = IR$.

$$V = IR = \left(\frac{V_0}{R_0}\right)R_0\frac{\ell - x}{\ell} = V_0\left(1 - \frac{x}{\ell}\right) = V_0\left(1 - f\right) \quad \rightarrow \quad \boxed{f = 1 - \frac{V}{V_0}}$$

Thus a measurement of the voltage can give the fraction of the tank that is filled with liquid helium.

96. We plot resistance vs. temperature. The graph is shown as follows, with no curve fitted to it. It is apparent that a linear fit will not be a good fit to this data. Both quadratic and exponential equations fit the data well, according to the R-squared coefficient as given by Excel. The equations and the predictions are given below.

$$R_{\text{exp}} = \left(30.1\times10^4 e^{-0.0442T}\right)\Omega$$

$$R_{\text{quad}} = \left[\left(7.39\times10^4\right)T^2 - 8200T + 25.9\times10^4\right]\Omega$$

Solving these expressions for $R = 57,641\Omega$ (using the spreadsheet) gives $T_{\text{exp}} = 37.402°\text{C}$ and $T_{\text{quad}} = 37.021°\text{C}$. So the temperature is probably in the range between those two values: $\boxed{37.021°\text{C} < T < 37.402°\text{C}}$. The average of those two values is $\boxed{T = 37.21°\text{C}}$. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH25.XLS," on tab "Problem 25.96."

As an extra comment, how might you choose between the exponential and quadratic fits? While they both give almost identical predictions for this intermediate temperature, they differ significantly at temperatures near $0°\text{C}$. The exponential fit would give a resistance of about $301,000\,\Omega$ at $0°\text{C}$, while the quadratic fit would give a resistance of about $259,000\ \Omega$ at $0°\text{C}$. So a measurement of resistance near $0°\text{C}$ might be very useful.

CHAPTER 26: DC Circuits

Responses to Questions

1. Even though the bird's feet are at high potential with respect to the ground, there is very little potential difference between them, because they are close together on the wire. The resistance of the bird is much greater than the resistance of the wire between the bird's feet. These two resistances are in parallel, so very little current will pass through the bird as it perches on the wire. When you put a metal ladder up against a power line, you provide a direct connection between the high potential line and ground. The ladder will have a large potential difference between its top and bottom. A person standing on the ladder will also have a large potential difference between his or her hands and feet. Even if the person's resistance is large, the potential difference will be great enough to produce a current through the person's body large enough to cause substantial damage or death.

2. Series: The main disadvantage of Christmas tree lights connected in series is that when one bulb burns out, a gap is created in the circuit and none of the bulbs remains lit. Finding the burned-out bulb requires replacing each individual bulb one at a time until the string of bulbs comes back on. As an advantage, the bulbs are slightly easier to wire in series.

   Parallel: The main advantage of connecting the bulbs in parallel is that one burned-out bulb does not affect the rest of the strand, and is easy to identify and replace. As a disadvantage, wiring the bulbs in parallel is slightly more difficult.

3. Yes. You can put 20 of the 6-V lights in series, or you can put several of the 6-V lights in series with a large resistance.

4. When the bulbs are connected in series, they have the same current through them. R_2, the bulb with the greater resistance, will be brighter in this case, since $P = I^2R$. When the bulbs are connected in parallel, they will have the same voltage across them. In this case, R_1, the bulb with the lower resistance, will have a larger current flowing through it and will be brighter: $P = V^2/R$.

5. Double outlets are connected in parallel, since each has 120 V across its terminals and they can be used independently.

6. Arrange the two batteries in series with each other and the two bulbs in parallel across the combined voltage of the batteries. This configuration maximizes the voltage gain and minimizes the equivalent resistance, yielding the maximum power.

7. The battery has to supply less power when the two resistors are connected in series than it has to supply when only one resistor is connected. $P = IV = \frac{V^2}{R}$, so if V is constant and R increases, the power decreases.

8. The overall resistance decreases and more current is drawn from the source. A bulb rated at 60-W and 120-V has a resistance of 240 Ω. A bulb rated at 100-W and 120-V has a resistance of 144 Ω. When only the 60-W bulb is on, the total resistance is 240 Ω. When both bulbs are lit, the total resistance is the combination of the two resistances in parallel, which is only 90 Ω.

9. No. The sign of the battery's emf does not depend on the direction of the current through the battery. Yes, the terminal voltage of the battery does depend on the direction of the current through the

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

battery. Note that the sign of the battery's emf in the loop equation does depend on the direction the loop is traversed (+ in the direction of the battery's potential, – in the opposite direction), and the terminal voltage sign and magnitude depend on whether the loop is traversed with or against the current.

10. When resistors are connected in *series*, the equivalent resistance is the *sum* of the individual resistances, $R_{eq,series} = R_1 + R_2 + \ldots$. The current has to go through each additional resistance if the resistors are in series and therefore the equivalent resistance is greater than any individual resistance. In contrast, when capacitors are in *parallel* the equivalent capacitance is equal to the sum of the individual capacitors, $C_{eq,parallel} = C_1 + C_2 + \ldots$. Charge drawn from the battery can go down any one of the different branches and land on any one of the capacitors, so the overall capacitance is greater than that of each individual capacitor.

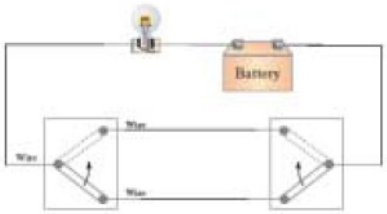
    When resistors are connected in *parallel*, the current from the battery or other source divides into the different branches and so the equivalent resistance is less than any individual resistor in the circuit. The corresponding expression is $1/R_{eq,parallel} = 1/R_1 + 1/R_2 + \ldots$. The formula for the equivalent capacitance of capacitors in *series* follows this same form, $1/C_{eq,series} = 1/C_1 + 1/C_2 + \ldots$. When capacitors are in series, the overall capacitance is less than the capacitance of any individual capacitor. Charge leaving the first capacitor lands on the second rather than going straight to the battery.

    Compare the expressions defining resistance ($R = V/I$) and capacitance ($C = Q/V$). Resistance is proportional to voltage, whereas capacitance is inversely proportional to voltage.

11. When batteries are connected in series, their emfs add together, producing a larger potential. The batteries do not need to be identical in this case. When batteries are connected in parallel, the currents they can generate add together, producing a larger current over a longer time period. Batteries in this case need to be nearly identical, or the battery with the larger emf will end up charging the battery with the smaller emf.

12. Yes. When a battery is being charged, current is forced through it "backwards" and then $V_{terminal} = \text{emf} + Ir$, so $V_{terminal} > \text{emf}$.

13. Put the battery in a circuit in series with a very large resistor and measure the terminal voltage. With a large resistance, the current in the circuit will be small, and the potential across the battery will be mainly due to the emf. Next put the battery in parallel with the large resistor (or in series with a small resistor) and measure the terminal voltage and the current in the circuit. You will have enough information to use the equation $V_{terminal} = \text{emf} - Ir$ to determine the internal resistance r.



14. No. As current passes through the resistor in the *RC* circuit, energy is dissipated in the resistor. Therefore, the total energy supplied by the battery during the charging is the combination of the energy dissipated in the resistor and the energy stored in the capacitor.

15. (*a*) Stays the same; (*b*) Increases; (*c*) Decreases; (*d*) Increases; (*e*) Increases; (*f*) Decreases; (*g*) Decreases; (*h*) Increases; (*i*) Remains the same.

16. The capacitance of a parallel plate capacitor is inversely proportional to the distance between the plates: ($C = \varepsilon_0 A/d$). As the diaphragm moves in and out, the distance between the plates changes and therefore the capacitance changes with the same frequency. This changes the amount of charge that can be stored on the capacitor, creating a current as the capacitor charges or discharges. The current oscillates with the same frequency as the diaphragm, which is the same frequency as the incident sound wave, and produces an oscillating V_{output}.

17. See the adjacent figure. If both switches are connected to the same wire, the circuit is complete and the light is on. If they are connected to opposite wires, the light will remain off.

18. In an analog ammeter, the internal resistor, or shunt resistor, has a small value and is in parallel with the galvanometer, so that the overall resistance of the ammeter is very small. In an analog voltmeter, the internal resistor has a large value and is in series with the galvanometer, and the overall resistance of the voltmeter is very large.

19. If you use an ammeter where you need to use a voltmeter, you will short the branch of the circuit. Too much current will pass through the ammeter and you will either blow the fuse on the ammeter or burn out its coil.

20. An ammeter is placed in series with a given circuit element in order to measure the current through that element. If the ammeter did not have very low (ideally, zero) resistance, its presence in the circuit would change the current it is attempting to measure by adding more resistance in series. An ideal ammeter has zero resistance and thus does not change the current it is measuring.

    A voltmeter is placed in parallel with a circuit element in order to measure the voltage difference across that element. If the voltmeter does not have a very high resistance, than its presence in parallel will lower the overall resistance and affect the circuit. An ideal voltmeter has infinite resistance so that when placed in parallel with circuit elements it will not change the value of the voltage it is reading.

21. When a voltmeter is connected across a resistor, the voltmeter is in parallel with the resistor. Even if the resistance of the voltmeter is large, the parallel combination of the resistor and the voltmeter will be slightly smaller than the resistor alone. If R_{eq} decreases, then the overall current will increase, so that the potential drop across the rest of the circuit will increase. Thus the potential drop across the parallel combination will be less than the original voltage drop across the resistor.

22. A voltmeter has a very high resistance. When it is connected to the battery very little current will flow. A small current results in a small voltage drop due to the internal resistance of the battery, and the emf and terminal voltage (measured by the voltmeter) will be very close to the same value. However, when the battery is connected to the lower-resistance flashlight bulb, the current will be higher and the voltage drop due to the internal resistance of the battery will also be higher. As a battery is used, its internal resistance increases. Therefore, the terminal voltage will be significantly lower than the emf: $V_{terminal} = \text{emf} - Ir$. A lower terminal voltage will result in a dimmer bulb, and usually indicates a "used-up" battery.

23. (*a*) With the batteries in series, a greater voltage is delivered to the lamp, and the lamp will burn brighter.
    (*b*) With the batteries in parallel, the voltage across the lamp is the same as for either battery alone. Each battery supplies only half of the current going through the lamp, so the batteries will last twice as long.

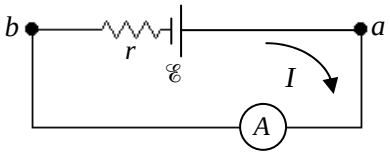
Solutions to Problems

1. See Figure 26-2 for a circuit diagram for this problem. Using the same analysis as in Example 26-1, the current in the circuit is $I = \dfrac{\mathscr{E}}{R+r}$. Use Eq. 26-1 to calculate the terminal voltage.

(*a*) $V_{ab} = \mathscr{E} - Ir = \mathscr{E} - \left(\dfrac{\mathscr{E}}{R+r}\right)r = \dfrac{\mathscr{E}(R+r) - \mathscr{E}r}{R+r} = \mathscr{E}\dfrac{R}{R+r} = (6.00\,\text{V})\dfrac{81.0\,\Omega}{(81.0+0.900)\,\Omega} = \boxed{5.93\,\text{V}}$

(*b*) $V_{ab} = \mathscr{E}\dfrac{R}{R+r} = (6.00\,\text{V})\dfrac{810\,\Omega}{(810+0.900)\,\Omega} = \boxed{5.99\,\text{V}}$

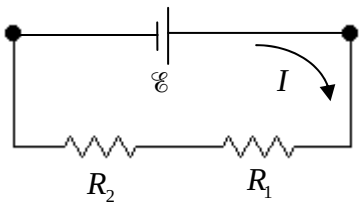


2. See the circuit diagram below. The current in the circuit is *I*. The voltage V_{ab} is given by Ohm's law to be $V_{ab} = IR$. That same voltage is the terminal voltage of the series EMF.

$V_{ab} = (\mathscr{E} - Ir) + (\mathscr{E} - Ir) + (\mathscr{E} - Ir) + (\mathscr{E} - Ir) = 4(\mathscr{E} - Ir)$ and $V_{ab} = IR$

$4(\mathscr{E} - Ir) = IR \;\rightarrow\; r = \dfrac{\mathscr{E} - \frac{1}{4}IR}{I} = \dfrac{(1.5\,\text{V}) - \frac{1}{4}(0.45\,\text{A})(12\,\Omega)}{0.45\,\text{A}} = 0.333\,\Omega \approx \boxed{0.3\,\Omega}$

3. We take the low-resistance ammeter to have no resistance. The circuit is shown. The terminal voltage will be 0 volts.



$V_{ab} = \mathscr{E} - Ir = 0 \;\rightarrow\; r = \dfrac{\mathscr{E}}{I} = \dfrac{1.5\,\text{V}}{25\,\text{A}} = \boxed{0.060\,\Omega}$

4. See Figure 26-2 for a circuit diagram for this problem. Use Eq. 26-1.

$V_{ab} = \mathscr{E} - Ir \;\rightarrow\; r = \dfrac{\mathscr{E} - V_{ab}}{I} = \dfrac{12.0\,\text{V} - 8.4\,\text{V}}{95\,\text{A}} = \boxed{0.038\,\Omega}$

$V_{ab} = IR \;\rightarrow\; R = \dfrac{V_{ab}}{I} = \dfrac{8.4\,\text{V}}{95\,\text{A}} = \boxed{0.088\,\Omega}$

5. The equivalent resistance is the sum of the two resistances: $R_{eq} = R_1 + R_2$. The current in the circuit is then the voltage divided by the equivalent resistance: $I = \dfrac{\mathscr{E}}{R_{eq}} = \dfrac{\mathscr{E}}{R_1 + R_2}$. The voltage across the 2200-Ω resistor is given by Ohm's law.

$V_{2200} = IR_2 = \dfrac{\mathscr{E}}{R_1 + R_2}R_2 = \mathscr{E}\dfrac{R_2}{R_1 + R_2} = (12.0\,\text{V})\dfrac{2200\,\Omega}{650\,\Omega + 2200\,\Omega} = \boxed{9.3\,\text{V}}$

6. (*a*) For the resistors in series, use Eq. 26-3, which says the resistances add linearly.

$$R_{eq} = 3(45\Omega) + 3(65\Omega) = \boxed{330\Omega}$$

(*b*) For the resistors in parallel, use Eq. 26-4, which says the resistances add reciprocally.

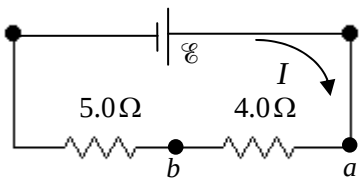
$$\frac{1}{R_{eq}} = \frac{1}{45\Omega} + \frac{1}{45\Omega} + \frac{1}{45\Omega} + \frac{1}{65\Omega} + \frac{1}{65\Omega} + \frac{1}{65\Omega} = \frac{3}{45\Omega} + \frac{3}{65\Omega} = \frac{3(65\Omega) + 3(45\Omega)}{(65\Omega)(45\Omega)} \rightarrow$$

$$R_{eq} = \frac{(65\Omega)(45\Omega)}{3(65\Omega) + 3(45\Omega)} = \boxed{8.9\Omega}$$

7. (*a*) The maximum resistance is made by combining the resistors in series.

$$R_{eq} = R_1 + R_2 + R_3 = 680\Omega + 720\Omega + 1200\Omega = \boxed{2.60\,\text{k}\Omega}$$

(*b*) The minimum resistance is made by combining the resistors in parallel.



$$\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} \rightarrow$$

$$R_{eq} = \left(\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}\right)^{-1} = \left(\frac{1}{680\Omega} + \frac{1}{720\Omega} + \frac{1}{1200\Omega}\right)^{-1} = \boxed{270\Omega}$$

8. The equivalent resistance of five 100-Ω resistors in parallel is found, and then that resistance is divided by 10Ω to find the number of 10-Ω resistors needed.

$$R_{eq} = \left(\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \frac{1}{R_4} + \frac{1}{R_5}\right)^{-1} = \left(\frac{5}{100\Omega}\right)^{-1} = 20\Omega = n(10\Omega) \rightarrow n = \frac{20\Omega}{10\Omega} = \boxed{2}$$

9. Connecting nine of the resistors in series will enable you to make a voltage divider with a 4.0 V output. To get the desired output, measure the voltage across four consecutive series resistors.

$$R_{eq} = 9(1.0\Omega) \qquad I = \frac{\mathscr{E}}{R_{eq}} = \frac{\mathscr{E}}{9.0\Omega}$$

$$V_{ab} = (4.0\Omega)I = (4.0\Omega)\frac{\mathscr{E}}{9.0\Omega} = (4.0\Omega)\frac{9.0\,\text{V}}{9.0\Omega} = \boxed{4.0\,\text{V}}$$

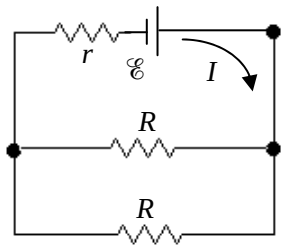
10. The resistors can all be connected in series.

$$R_{eq} = R + R + R = 3(1.70\,\text{k}\Omega) = \boxed{5.10\,\text{k}\Omega}$$

The resistors can all be connected in parallel.

$$\frac{1}{R_{eq}} = \frac{1}{R} + \frac{1}{R} + \frac{1}{R} \rightarrow R_{eq} = \left(\frac{3}{R}\right)^{-1} = \frac{R}{3} = \frac{1.70\,\text{k}\Omega}{3} = \boxed{567\Omega}$$

Two resistors in series can be placed in parallel with the third.



$$\frac{1}{R_{eq}} = \frac{1}{R} + \frac{1}{R+R} = \frac{1}{R} + \frac{1}{2R} = \frac{3}{2R} \rightarrow R_{eq} = \frac{2R}{3} = \frac{2(1.70\,\text{k}\Omega)}{3} = \boxed{1.13\,\text{k}\Omega}$$

Two resistors in parallel can be placed in series with the third.

$$R_{eq} = R + \left(\frac{1}{R} + \frac{1}{R}\right)^{-1} = R + \frac{R}{2} = \frac{3}{2}(1.70\,\text{k}\Omega) = \boxed{2.55\,\text{k}\Omega}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11. The resistance of each bulb can be found from its power rating.

$$P = \frac{V^2}{R} \quad \rightarrow \quad R = \frac{V^2}{P} = \frac{(12.0\,\text{V})^2}{4.0\,\text{W}} = 36\,\Omega$$

Find the equivalent resistance of the two bulbs in parallel.

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R} + \frac{1}{R} = \frac{2}{R} \quad \rightarrow \quad R_{\text{eq}} = \frac{R}{2} = \frac{36\,\Omega}{2} = 18\,\Omega$$

The terminal voltage is the voltage across this equivalent resistance. Use that to find the current drawn from the battery.

$$V_{\text{ab}} = IR_{\text{eq}} \quad \rightarrow \quad I = \frac{V_{\text{ab}}}{R_{\text{eq}}} = \frac{V_{\text{ab}}}{R/2} = \frac{2V_{\text{ab}}}{R}$$

Finally, use the terminal voltage and the current to find the internal resistance, as in Eq. 26-1.

$$V_{\text{ab}} = \mathscr{E} - Ir \quad \rightarrow \quad r = \frac{\mathscr{E} - V_{\text{ab}}}{I} = \frac{\mathscr{E} - V_{\text{ab}}}{\left(\frac{2V_{\text{ab}}}{R}\right)} = R\frac{\mathscr{E} - V_{\text{ab}}}{2V_{\text{ab}}} = (36\,\Omega)\frac{12.0\,\text{V} - 11.8\,\text{V}}{2(11.8\,\text{V})} = 0.305\,\Omega \approx \boxed{0.3\,\Omega}$$

12. (*a*) Each bulb should get one-eighth of the total voltage, but let us prove that instead of assuming it. Since the bulbs are identical, the net resistance is $R_{\text{eq}} = 8R$. The current flowing through the bulbs is then $V_{\text{tot}} = IR_{\text{eq}} \quad \rightarrow \quad I = \frac{V_{\text{tot}}}{R_{\text{eq}}} = \frac{V_{\text{tot}}}{8R}$. The voltage across one bulb is found from Ohm's law.

$$V = IR = \frac{V_{\text{tot}}}{8R}R = \frac{V_{\text{tot}}}{8} = \frac{110\,\text{V}}{8} = 13.75\,\text{V} \approx \boxed{14\,\text{V}}$$

(*b*) $I = \frac{V_{\text{tot}}}{8R} \quad \rightarrow \quad R = \frac{V_{\text{tot}}}{8I} = \frac{110\,\text{V}}{8(0.42\,\text{A})} = 32.74\,\Omega \approx \boxed{33\,\Omega}$

$$P = I^2R = (0.42\,\text{A})^2(32.74\,\Omega) = 5.775\,\text{W} \approx \boxed{5.8\,\text{W}}$$

13. We model the resistance of the long leads as a single resistor *r*. Since the bulbs are in parallel, the total current is the sum of the current in each bulb, and so $I = 8I_R$. The voltage drop across the long leads is $V_{\text{leads}} = Ir = 8I_Rr = 8(0.24\,\text{A})(1.4\,\Omega) = 2.688\,\text{V}$. Thus the voltage across each of the parallel resistors is $V_R = V_{\text{tot}} - V_{\text{leads}} = 110\,\text{V} - 2.688\,\text{V} = 107.3\,\text{V}$. Since we have the current through each resistor, and the voltage across each resistor, we calculate the resistance using Ohm's law.

$$V_R = I_RR \quad \rightarrow \quad R = \frac{V_R}{I_R} = \frac{107.3\,\text{V}}{0.24\,\text{A}} = 447.1\,\Omega = \boxed{450\,\Omega}$$

The total power delivered is $P = V_{\text{tot}}I$, and the "wasted" power is I^2r. The fraction wasted is the ratio of those powers.

$$\text{fraction wasted} = \frac{I^2r}{IV_{\text{tot}}} = \frac{Ir}{V_{\text{tot}}} = \frac{8(0.24\,\text{A})(1.4\,\Omega)}{110\,\text{V}} = \boxed{0.024}$$

So about 2.5% of the power is wasted.

14. The power delivered to the starter is equal to the square of the current in the circuit multiplied by the resistance of the starter. Since the resistors in each circuit are in series we calculate the currents as the battery emf divided by the sum of the resistances.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{P}{P_0}=\frac{I^2R_S}{I_0^2R_S}=\left(\frac{I}{I_0}\right)^2=\left(\frac{\mathscr{E}/R_{eq}}{\mathscr{E}/R_{0eq}}\right)^2=\left(\frac{R_{0eq}}{R_{eq}}\right)^2=\left(\frac{r+R_S}{r+R_S+R_C}\right)^2$$

$$=\left(\frac{0.02\,\Omega+0.15\,\Omega}{0.02\,\Omega+0.15\,\Omega+0.10\,\Omega}\right)^2=\boxed{0.40}$$

15. To fix this circuit, connect another resistor in parallel with the 480-Ω resistor so that the equivalent resistance is the desired 370 Ω.

$$\frac{1}{R_{eq}}=\frac{1}{R_1}+\frac{1}{R_2}\quad\rightarrow\quad R_2=\left(\frac{1}{R_{eq}}-\frac{1}{R_1}\right)^{-1}=\left(\frac{1}{370\,\Omega}-\frac{1}{480\,\Omega}\right)^{-1}=1615\,\Omega\approx\boxed{1600\,\Omega}$$

So solder a 1600-Ω resistor in parallel with the 480-Ω resistor.

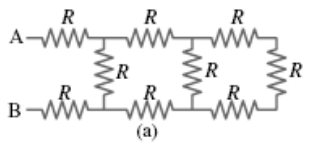
16. (*a*) The equivalent resistance is found by combining the 820 Ω and 680 Ω resistors in parallel, and then adding the 960 Ω resistor in series with that parallel combination.

$$R_{eq}=\left(\frac{1}{820\,\Omega}+\frac{1}{680\,\Omega}\right)^{-1}+960\,\Omega=372\,\Omega+960\,\Omega=1332\,\Omega\approx\boxed{1330\,\Omega}$$

(*b*) The current delivered by the battery is $I=\dfrac{V}{R_{eq}}=\dfrac{12.0\,\text{V}}{1332\,\Omega}=9.009\times10^{-3}\,\text{A}$. This is the current in the 960 Ω resistor. The voltage across that resistor can be found by Ohm's law.

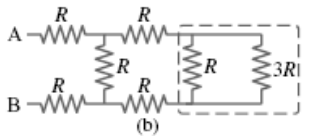
$$V_{470}=IR=\left(9.009\times10^{-3}\,\text{A}\right)\left(960\,\Omega\right)=8.649\,\text{V}\approx\boxed{8.6\,\text{V}}$$

Thus the voltage across the parallel combination must be $12.0\,\text{V}-8.6\,\text{V}=\boxed{3.4\,\text{V}}$. This is the voltage across both the 820 Ω and 680 Ω resistors, since parallel resistors have the same voltage across them. Note that this voltage value could also be found as follows.



$$V_{\text{parallel}}=IR_{\text{parallel}}=\left(9.009\times10^{-3}\,\text{A}\right)\left(372\,\Omega\right)=3.351\text{V}\approx3.4\,\text{V}$$

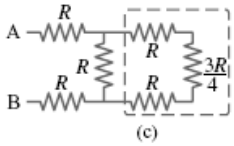
17. The resistance of each bulb can be found by using Eq. 25-7b, $P=V^2/R$. The two individual resistances are combined in parallel. We label the bulbs by their wattage.



$$P=V^2/R\quad\rightarrow\quad\frac{1}{R}=\frac{P}{V^2}$$

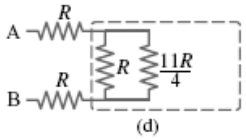
$$R_{eq}=\left(\frac{1}{R_{75}}+\frac{1}{R_{40}}\right)^{-1}=\left(\frac{75\,\text{W}}{(110\,\text{V})^2}+\frac{25\,\text{W}}{(110\,\text{V})^2}\right)^{-1}=121\,\Omega\approx\boxed{120\,\Omega}$$

18. (*a*) The three resistors on the far right are in series, so their equivalent resistance is 3*R*. That combination is in parallel with the next resistor to the left, as shown in the dashed box in the second figure. The equivalent resistance of the dashed box is found as follows.



$$R_{eq1}=\left(\frac{1}{R}+\frac{1}{3R}\right)^{-1}=\tfrac{3}{4}R$$

This equivalent resistance of $\frac{3}{4}R$ is in series with the next two resistors, as shown in the dashed box in the third figure (on the next page). The equivalent resistance of that dashed box is $R_{eq2}=2R+\frac{3}{4}R=\frac{11}{4}R$. This $\frac{11}{4}R$ is in



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

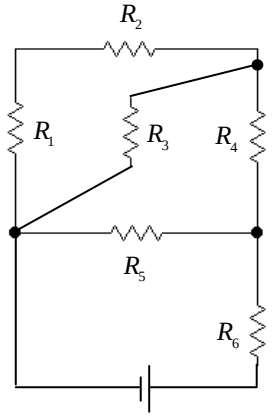
parallel with the next resistor to the left, as shown in the fourth figure. The equivalent resistance of that dashed box is found as follows.

$$R_{\text{eq2}} = \left(\frac{1}{R} + \frac{4}{11R}\right)^{-1} = \tfrac{11}{15}R.$$

This is in series with the last two resistors, the ones connected directly to A and B. The final equivalent resistance is given below.

$$R_{\text{eq}} = 2R + \tfrac{11}{15}R = \tfrac{41}{15}R = \tfrac{41}{15}(125\,\Omega) = 341.67\,\Omega \approx \boxed{342\,\Omega}$$

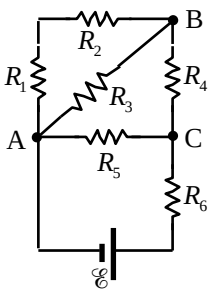
(*b*) The current flowing from the battery is found from Ohm's law.



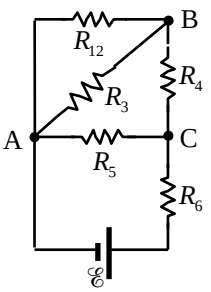
$$I_{\text{total}} = \frac{V}{R_{\text{eq}}} = \frac{50.0\,\text{V}}{341.67\,\Omega} = 0.1463\text{A} \approx \boxed{0.146\,\text{A}}$$

This is the current in the top and bottom resistors. There will be less current in the next resistor because the current splits, with some current passing through the resistor in question, and the rest of the current passing through the equivalent resistance of $\frac{11}{4}R$, as shown in the last figure. The voltage across R and across $\frac{11}{4}R$ must be the same, since they are in parallel. Use this to find the desired current.

$$V_R = V_{\frac{11}{4}R} \;\rightarrow\; I_R R = I_{\frac{11}{4}R}\left(\tfrac{11}{4}R\right) = \left(I_{\text{total}} - I_R\right)\left(\tfrac{11}{4}R\right) \;\rightarrow$$



$$I_R = \tfrac{11}{15}I_{\text{total}} = \tfrac{11}{15}(0.1463\,\text{A})\,I_{\text{total}} = \boxed{0.107\,\text{A}}$$



19. The resistors have been numbered in the accompanying diagram to help in the analysis. R_1 and R_2 are in series with an equivalent resistance of $R_{12} = R + R = 2R$. This combination is in parallel with R_3, with an equivalent resistance of $R_{123} = \left(\frac{1}{R} + \frac{1}{2R}\right)^{-1} = \frac{2}{3}R$. This combination is in series with R_4, with an equivalent resistance of $R_{1234} = \frac{2}{3}R + R = \frac{5}{3}R$. This combination is in parallel with R_5, with an equivalent resistance of $R_{12345} = \left(\frac{1}{R} + \frac{3}{5R}\right)^{-1} = \frac{5}{8}R$. Finally, this combination is in series with R_6, and we calculate the final equivalent resistance.

$$R_{\text{eq}} = \tfrac{5}{8}R + R = \boxed{\tfrac{13}{8}R}$$

20. We reduce the circuit to a single loop by combining series and parallel combinations. We label a combined resistance with the subscripts of the resistors used in the combination. See the successive diagrams.

R_1 and R_2 are in series.

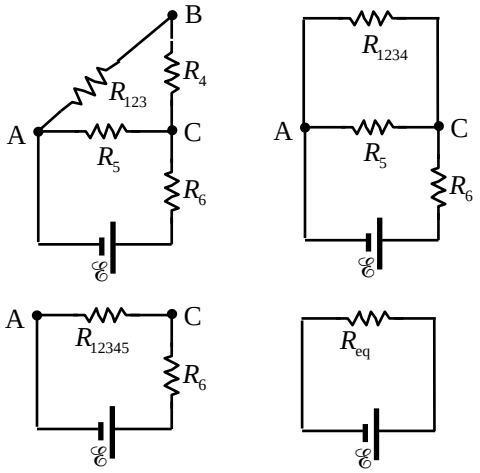
$$R_{12} = R_1 + R_2 = R + R = 2R$$

R_{12} and R_3 are in parallel.

$$R_{123} = \left(\frac{1}{R_{12}} + \frac{1}{R_3}\right)^{-1} = \left(\frac{1}{2R} + \frac{1}{R}\right)^{-1} = \tfrac{2}{3}R$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

R_{123} and R_4 are in series.



$$R_{1234} = R_{123} + R_4 = \tfrac{2}{3}R + R = \tfrac{5}{3}R$$

R_{1234} and R_5 are in parallel.

$$R_{12345} = \left(\frac{1}{R_{1234}} + \frac{1}{R_5}\right)^{-1} = \left(\frac{1}{\frac{5}{3}R} + \frac{1}{R}\right)^{-1} = \tfrac{5}{8}R$$

R_{12345} and R_6 are in series, producing the equivalent resistance.

$$R_{\text{eq}} = R_{12345} + R_6 = \tfrac{5}{8}R + R = \tfrac{13}{8}R$$

Now work "backwards" from the simplified circuit. Resistors in series have the same current as their equivalent resistance, and resistors in parallel have the same voltage as their equivalent resistance. To avoid rounding errors, we do not use numeric values until the end of the problem.

$$I_{\text{eq}} = \frac{\mathscr{E}}{R_{\text{eq}}} = \frac{\mathscr{E}}{\frac{13}{8}R} = \boxed{\frac{8\mathscr{E}}{13R} = I_6} = I_{12345}$$

$$V_5 = V_{1234} = V_{12345} = I_{12345}R_{12345} = \left(\frac{8\mathscr{E}}{13R}\right)\left(\tfrac{5}{8}R\right) = \tfrac{5}{13}\mathscr{E} \;;\; I_5 = \frac{V_5}{R_5} = \frac{\frac{5}{13}\mathscr{E}}{R} = \boxed{\frac{5\mathscr{E}}{13R} = I_5}$$

$$I_{1234} = \frac{V_{1234}}{R_{1234}} = \frac{\frac{5}{13}\mathscr{E}}{\frac{5}{3}R} = \boxed{\frac{3\mathscr{E}}{13R} = I_4} = I_{123} \;;\; V_{123} = I_{123}R_{123} = \left(\frac{3\mathscr{E}}{13R}\right)\left(\tfrac{2}{3}R\right) = \tfrac{2}{13}\mathscr{E} = V_{12} = V_3$$

$$I_3 = \frac{V_3}{R_3} = \boxed{\frac{2\mathscr{E}}{13R} = I_3} \;;\; I_{12} = \frac{V_{12}}{R_{12}} = \frac{\frac{2}{13}\mathscr{E}}{2R} = \boxed{\frac{\mathscr{E}}{13R} = I_1 = I_2}$$

Now substitute in numeric values.

$$I_1 = I_2 = \frac{\mathscr{E}}{13R} = \frac{12.0\,\text{V}}{13(1.20\,\text{k}\Omega)} = \boxed{0.77\,\text{mA}} \;;\; I_3 = \frac{2\mathscr{E}}{13R} = \boxed{1.54\,\text{mA}} \;;\; I_4 = \frac{3\mathscr{E}}{13R} = \boxed{2.31\,\text{mA}} \;;$$

$$I_5 = \frac{5\mathscr{E}}{13R} = \boxed{3.85\,\text{mA}} \;;\; I_6 = \frac{8\mathscr{E}}{13R} = \boxed{6.15\,\text{mA}} \;;\; V_{\text{AB}} = V_3 = \tfrac{2}{13}\mathscr{E} = \boxed{1.85\,\text{V}}$$

21. The resistors *r* and *R* are in series, so the equivalent resistance of the circuit is $R + r$ and the current in the resistors is $I = \dfrac{\mathscr{E}}{R+r}$. The power delivered to load resistor is found from Eq. 25-7a. To find the value of *R* that maximizes this delivered power, set $\dfrac{dP}{dR} = 0$ and solve for *R*.

$$P = I^2R = \left(\frac{\mathscr{E}}{R+r}\right)R = \frac{\mathscr{E}^2R}{(R+r)^2} \;;\; \frac{dP}{dR} = \mathscr{E}^2\left[\frac{(R+r)^2 - R(2)(R+r)}{(R+r)^4}\right] = 0 \;\rightarrow$$

$$(R+r)^2 - R(2)(R+r) = 0 \;\rightarrow\; R^2 + 2Rr + r^2 - 2R^2 - 2Rr = 0 \;\rightarrow\; \boxed{R = r}$$

22. It is given that the power used when the resistors are in series is one-fourth the power used when the resistors are in parallel. The voltage is the same in both cases. Use Eq. 25-7b, along with the definitions of series and parallel equivalent resistance.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$P_{\text{series}} = \tfrac{1}{4}P_{\text{parallel}} \;\rightarrow\; \frac{V^2}{R_{\text{series}}} = \tfrac{1}{4}\frac{V^2}{R_{\text{parallel}}} \;\rightarrow\; R_{\text{series}} = 4R_{\text{parallel}} \;\rightarrow\; \left(R_1 + R_2\right) = 4\frac{R_1R_2}{\left(R_1 + R_2\right)} \;\rightarrow$$

$$\left(R_1 + R_2\right)^2 = 4R_1R_2 \;\rightarrow\; R_1^2 + 2R_1R_2 + R_2^2 - 4R_1R_2 = 0 = \left(R_1 - R_2\right)^2 \;\rightarrow\; R_1 = R_2$$

Thus the two resistors must be the same, and so the "other" resistor is $\boxed{3.8\,\text{k}\Omega}$.

23. We label identical resistors from left to right as R_{left}, R_{middle}, and R_{right}. When the switch is opened, the equivalent resistance of the circuit increases from $\frac{3}{2}R + r$ to $2R + r$. Thus the current delivered by the battery decreases, from $\dfrac{\mathscr{E}}{\frac{3}{2}R + r}$ to $\dfrac{\mathscr{E}}{2R + r}$. Note that this is LESS than a 50% decrease.

(*a*) Because the current from the battery has decreased, the voltage drop across R_{left} will decrease, since it will have less current than before. The voltage drop across R_{right} decreases to 0, since no current is flowing in it. The voltage drop across R_{middle} will increase, because even though the total current has decreased, the current flowing through R_{middle} has increased since before the switch was opened, only half the total current was flowing through R_{middle}.

$\boxed{V_{\text{left}} \text{ decreases ; } V_{\text{middle}} \text{ increases ; } V_{\text{right}} \text{ goes to 0}}$.

(*b*) By Ohm's law, the current is proportional to the voltage for a fixed resistance.

$\boxed{I_{\text{left}} \text{ decreases ; } I_{\text{middle}} \text{ increases ; } I_{\text{right}} \text{ goes to 0}}$

(*c*) Since the current from the battery has decreased, the voltage drop across *r* will decrease, and thus the $\boxed{\text{terminal voltage increases}}$.

(*d*) With the switch closed, the equivalent resistance is $\frac{3}{2}R + r$. Thus the current in the circuit is $I_{\text{closed}} = \dfrac{\mathscr{E}}{\frac{3}{2}R + r}$, and the terminal voltage is given by Eq. 26-1.

$$V_{\substack{\text{terminal}\\\text{closed}}} = \mathscr{E} - I_{\text{closed}}r = \mathscr{E} - \frac{\mathscr{E}}{\frac{3}{2}R + r}r = \mathscr{E}\left(1 - \frac{r}{\frac{3}{2}R + r}\right) = \left(9.0\,\text{V}\right)\left(1 - \frac{0.50\,\Omega}{\frac{3}{2}\left(5.50\,\Omega\right) + 0.50\,\Omega}\right)$$

$$= 8.486\,\text{V} \approx \boxed{8.5\,\text{V}}$$

(*e*) With the switch open, the equivalent resistance is $2R + r$. Thus the current in the circuit is $I_{\text{closed}} = \dfrac{\mathscr{E}}{2R + r}$, and again the terminal voltage is given by Eq. 26-1.

$$V_{\substack{\text{terminal}\\\text{closed}}} = \mathscr{E} - I_{\text{closed}}r = \mathscr{E} - \frac{\mathscr{E}}{2R + r}r = \mathscr{E}\left(1 - \frac{r}{2R + r}\right) = \left(9.0\,\text{V}\right)\left(1 - \frac{0.50\,\Omega}{2\left(5.50\,\Omega\right) + 0.50\,\Omega}\right)$$

$$= 8.609\,\text{V} \approx \boxed{8.6\,\text{V}}$$

24. Find the maximum current and resulting voltage for each resistor under the power restriction.

$$P = I^2R = \frac{V^2}{R} \;\rightarrow\; I = \sqrt{\frac{P}{R}}\,,\; V = \sqrt{RP}$$

$$I_{1800} = \sqrt{\frac{0.5\,\text{W}}{1.8\times10^3\,\Omega}} = 0.0167\,\text{A} \qquad V_{1800} = \sqrt{\left(0.5\,\text{W}\right)\left(1.8\times10^3\,\Omega\right)} = 30.0\,\text{V}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_{2800} = \sqrt{\frac{0.5\,\text{W}}{2.8\times10^3\,\Omega}} = 0.0134\,\text{A} \qquad V_{2800} = \sqrt{(0.5\,\text{W})(2.8\times10^3\,\Omega)} = 37.4\,\text{V}$$

$$I_{3700} = \sqrt{\frac{0.5\,\text{W}}{3.7\times10^3\,\Omega}} = 0.0116\,\text{A} \qquad V_{3700} = \sqrt{(0.5\,\text{W})(3.7\times10^3\,\Omega)} = 43.0\,\text{V}$$

The parallel resistors have to have the same voltage, and so the voltage across that combination is limited to 37.4 V. That would require a current given by Ohm's law and the parallel combination of the two resistors.

$$I_{\text{parallel}} = \frac{V_{\text{parallel}}}{R_{\text{parallel}}} = V_{\text{parallel}}\left(\frac{1}{R_{2800}} + \frac{1}{R_{2100}}\right) = (37.4\,\text{V})\left(\frac{1}{2800\,\Omega} + \frac{1}{3700\,\Omega}\right) = 0.0235\,\text{A}$$

This is more than the maximum current that can be in R_{1800}. Thus the maximum current that R_{1800} can carry, $0.0167\,\text{A}$, is the maximum current for the circuit. The maximum voltage that can be applied across the combination is the maximum current times the equivalent resistance. The equivalent resistance is the parallel combination of R_{2800} and R_{3700} added to R_{1800}.

$$V_{\max} = I_{\max}R_{\text{eq}} = I_{\max}\left[R_{1800} + \left(\frac{1}{R_{2800}} + \frac{1}{R_{3700}}\right)^{-1}\right] = (0.0167\,\text{A})\left[1800\,\Omega + \left(\frac{1}{2800\,\Omega} + \frac{1}{3700\,\Omega}\right)^{-1}\right]$$

$$= 56.68\text{V} \approx \boxed{57\,\text{V}}$$

25. (*a*) Note that adding resistors in series always results in a larger resistance, and adding resistors in parallel always results in a smaller resistance. Closing the switch adds another resistor in parallel with R_3 and R_4, which lowers the net resistance of the parallel portion of the circuit, and thus lowers the equivalent resistance of the circuit. That means that more current will be delivered by the battery. Since R_1 is in series with the battery, its voltage will increase. Because of that increase, the voltage across R_3 and R_4 must decrease so that the total voltage drops around the loop are equal to the battery voltage. Since there was no voltage across R_2 until the switch was closed, its voltage will increase. To summarize:

$\boxed{V_1 \text{ and } V_2 \text{ increase}\,;\, V_3 \text{ and } V_4 \text{ decrease}}$

(*b*) By Ohm's law, the current is proportional to the voltage for a fixed resistance. Thus

$\boxed{I_1 \text{ and } I_2 \text{ increase}\,;\, I_3 \text{ and } I_4 \text{ decrease}}$

(*c*) Since the battery voltage does not change and the current delivered by the battery increases, the power delivered by the battery, found by multiplying the voltage of the battery by the current delivered, $\boxed{\text{increases}}$.

(*d*) Before the switch is closed, the equivalent resistance is R_3 and R_4 in parallel, combined with R_1 in series.

$$R_{\text{eq}} = R_1 + \left(\frac{1}{R_3} + \frac{1}{R_4}\right)^{-1} = 125\,\Omega + \left(\frac{2}{125\,\Omega}\right)^{-1} = 187.5\,\Omega$$

The current delivered by the battery is the same as the current through R_1.

$$I_{\text{total}} = \frac{V_{\text{battery}}}{R_{\text{eq}}} = \frac{22.0\,\text{V}}{187.5\,\Omega} = 0.1173\,\text{A} = I_1$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The voltage across R_1 is found by Ohm's law.

$$V_1 = IR_1 = (0.1173\,\text{A})(125\,\Omega) = 14.66\,\text{V}$$

The voltage across the parallel resistors is the battery voltage less the voltage across R_1.

$$V_\text{p} = V_\text{battery} - V_1 = 22.0\,\text{V} - 14.66\,\text{V} = 7.34\,\text{V}$$

The current through each of the parallel resistors is found from Ohm's law.

$$I_3 = \frac{V_\text{p}}{R_2} = \frac{7.34\,\text{V}}{125\,\Omega} = 0.0587\,\text{A} = I_4$$

Notice that the current through each of the parallel resistors is half of the total current, within the limits of significant figures. The currents before closing the switch are as follows.

$$\boxed{I_1 = 0.117\,\text{A} \quad I_3 = I_4 = 0.059\,\text{A}}$$

After the switch is closed, the equivalent resistance is R_2, R_3, and R_4 in parallel, combined with R_1 in series. Do a similar analysis.

$$R_\text{eq} = R_1 + \left(\frac{1}{R_2} + \frac{1}{R_3} + \frac{1}{R_4}\right)^{-1} = 125\,\Omega + \left(\frac{3}{125\,\Omega}\right)^{-1} = 166.7\,\Omega$$

$$I_\text{total} = \frac{V_\text{battery}}{R_\text{eq}} = \frac{22.0\,\text{V}}{166.7\,\Omega} = 0.1320\,\text{A} = I_1 \qquad V_1 = IR_1 = (0.1320\,\text{A})(125\,\Omega) = 16.5\,\text{V}$$

$$V_\text{p} = V_\text{battery} - V_1 = 22.0\,\text{V} - 16.5\,\text{V} = 5.5\,\text{V} \qquad I_2 = \frac{V_\text{p}}{R_2} = \frac{5.5\,\text{V}}{125\,\Omega} = 0.044\,\text{A} = I_3 = I_4$$

Notice that the current through each of the parallel resistors is one third of the total current, within the limits of significant figures. The currents after closing the switch are as follows.

$$\boxed{I_1 = 0.132\,\text{A} \quad I_2 = I_3 = I_4 = 0.044\,\text{A}}$$

Yes, the predictions made in part (*b*) are all confirmed.

26. The goal is to determine *r* so that $\left.\frac{dP_R}{dR}\right|_{R=R_0} = 0$. This ensures that *R* produce very little change in P_R, since $\Delta P_R \approx \frac{dP_R}{dR}\Delta R$. The power delivered to the heater can be found by $P_\text{heater} = V_\text{heater}^2 / R$, and so we need to determine the voltage across the heater. We do this by calculating the current drawn from the voltage source, and then subtracting the voltage drop across *r* from the source voltage.

$$R_\text{eq} = r + \frac{Rr}{R+r} = \frac{2Rr + r^2}{R+r} = \frac{r(2R+r)}{R+r} \;\; ; \;\; I_\text{total} = \frac{\mathscr{E}}{R_\text{eq}} = \frac{\mathscr{E}}{\frac{r(2R+r)}{R+r}} = \frac{\mathscr{E}(R+r)}{r(2R+r)}$$

$$V_\text{heater} = \mathscr{E} - I_\text{total} r = \mathscr{E} - \frac{\mathscr{E}(R+r)}{r(2R+r)} r = \mathscr{E} - \frac{\mathscr{E}(R+r)}{(2R+r)} = \frac{\mathscr{E}R}{(2R+r)} \;\; ; \;\; P_\text{heater} = \frac{V_\text{heater}^2}{R} = \frac{\mathscr{E}^2 R}{(2R+r)^2}$$

$$\left.\frac{dP_\text{heater}}{dR}\right|_{R=R_0} = \mathscr{E}^2 \frac{(2R_0+r)^2 - R_0(2)(2R_0+r)(2)}{(2R_0+r)^4} = 0 \;\; \rightarrow \;\; (2R_0+r)^2 - R_0(2)(2R_0+r)(2) = 0 \;\; \rightarrow$$

$$4R_0^2 + 4R_0 r + r^2 - 8R_0^2 - 4R_0 r = 0 \;\; \rightarrow \;\; r^2 = 4R_0^2 \;\; \rightarrow \;\; \boxed{r = 2R_0}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

27. All of the resistors are in series, so the equivalent resistance is just the sum of the resistors. Use Ohm's law then to find the current, and show all voltage changes starting at the negative pole of the battery and going counterclockwise.

$$I = \frac{\mathcal{E}}{R_{\text{eq}}} = \frac{9.0\,\text{V}}{(9.5+12.0+2.0)\,\Omega} = 0.383\,\text{A} \approx \boxed{0.38\,\text{A}}$$

$$\sum \text{voltages} = 9.0\,\text{V} - (9.5\,\Omega)(0.383\,\text{A}) - (12.0\,\Omega)(0.383\,\text{A}) - (2.0\,\Omega)(0.383\,\text{A})$$

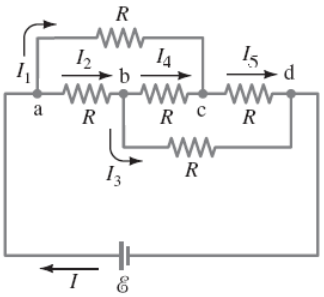
$$= 9.0\,\text{V} - 3.638\,\text{V} - 4.596\,\text{V} - 0.766\,\text{V} = \boxed{0.00\,\text{V}}$$

28. Apply Kirchhoff's loop rule to the circuit starting at the upper left corner of the circuit diagram, in order to calculate the current. Assume that the current is flowing clockwise.

$$-I(2.0\,\Omega) + 18\,\text{V} - I(6.6\,\Omega) - 12\,\text{V} - I(1.0\,\Omega) = 0 \;\rightarrow\; I = \frac{6\,\text{V}}{9.6\,\Omega} = 0.625\text{A}$$

The terminal voltage for each battery is found by summing the potential differences across the internal resistance and EMF from left to right. Note that for the 12 V battery, there is a voltage gain going across the internal resistance from left to right.

18 V battery: $V_{\text{terminal}} = -I(2.0\,\Omega) + 18\,\text{V} = -(0.625\,\text{A})(2.0\,\Omega) + 18\,\text{V} = 16.75\text{V} \approx \boxed{17\,\text{V}}$



12 V battery: $V_{\text{terminal}} = I(1.0\,\Omega) + 12\,\text{V} = (0.625\,\text{A})(1.0\,\Omega) + 12\,\text{V} = 12.625\,\text{V} \approx \boxed{13\,\text{V}}$

29. To find the potential difference between points a and b, the current must be found from Kirchhoff's loop law. Start at point a and go counterclockwise around the entire circuit, taking the current to be counterclockwise.

$$-IR + \mathcal{E} - IR - IR + \mathcal{E} - IR = 0 \;\rightarrow\; I = \frac{\mathcal{E}}{2R}$$

$$V_{\text{ab}} = V_{\text{a}} - V_{\text{b}} = -IR + \mathcal{E} - IR = \mathcal{E} - 2IR = \mathcal{E} - 2\frac{\mathcal{E}}{2R}R = \boxed{0\,\text{V}}$$

30. (*a*) We label each of the currents as shown in the accompanying figure. Using Kirchhoff's junction rule and the first three junctions (a-c) we write equations relating the entering and exiting currents.

$$I = I_1 + I_2 \qquad [1]$$

$$I_2 = I_3 + I_4 \qquad [2]$$

$$I_1 + I_4 = I_5 \qquad [3]$$

We use Kirchhoff's loop rule to write equations for loops abca, abcda, and bdcb.

$$0 = -I_2R - I_4R + I_1R \qquad [4]$$

$$0 = -I_2R - I_3R + \mathcal{E} \qquad [5]$$

$$0 = -I_3R + I_5R + I_4R \qquad [6]$$

We have six unknown currents and six equations. We solve these equations by substitution. First, insert Eq. [3] into [6] to eliminate current I_5. Next insert Eq. [2] into Eqs. [1], [4], and [5] to eliminate I_2.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$0 = -I_3R + (I_1 + I_4)R + I_4R \rightarrow 0 = -I_3R + I_1R + 2I_4R \qquad [6^*]$$
$$I = I_1 + I_3 + I_4 \qquad [1^*]$$
$$0 = -(I_3 + I_4)R - I_4R + I_1R \rightarrow 0 = -I_3R - 2I_4R + I_1R \qquad [4^*]$$
$$0 = -(I_3 + I_4)R - I_3R + \mathscr{E} \rightarrow 0 = -I_4R - 2I_3R + \mathscr{E} \qquad [5^*]$$

Next we solve Eq. [4*] for I_4 and insert the result into Eqs. [1*], [5*], and [6*].

$$0 = -I_3R - 2I_4R + I_1R \rightarrow I_4 = \tfrac{1}{2}I_1 - \tfrac{1}{2}I_3$$
$$I = I_1 + I_3 + \tfrac{1}{2}I_1 - \tfrac{1}{2}I_3 \rightarrow I = \tfrac{3}{2}I_1 + \tfrac{1}{2}I_3 \qquad [1^{**}]$$
$$0 = -I_3R + I_1R + 2(\tfrac{1}{2}I_1 - \tfrac{1}{2}I_3)R = -2I_3R + 2I_1R \rightarrow I_1 = I_3 \qquad [6^{**}]$$
$$0 = -(\tfrac{1}{2}I_1 - \tfrac{1}{2}I_3)R - 2I_3R + \mathscr{E} \rightarrow 0 = -\tfrac{1}{2}I_1R - \tfrac{3}{2}I_3R + \mathscr{E} \qquad [5^{**}]$$

Finally we substitute Eq. [6**] into Eq [5**] and solve for I_1. We insert this result into Eq. [1**] to write an equation for the current through the battery in terms of the battery emf and resistance.

$$0 = -\tfrac{1}{2}I_1R - \tfrac{3}{2}I_1R + \mathscr{E} \rightarrow I_1 = \frac{\mathscr{E}}{2R} \;;\; I = \tfrac{3}{2}I_1 + \tfrac{1}{2}I_1 = 2I_1 \rightarrow \boxed{I = \frac{\mathscr{E}}{R}}$$

(*b*) We divide the battery emf by the current to determine the effective resistance.

$$R_{eq} = \frac{\mathscr{E}}{I} = \frac{\mathscr{E}}{\mathscr{E}/R} = \boxed{R}$$

31. This circuit is identical to Example 26-9 and Figure 26-13 except for the numeric values. So we may copy the same equations as developed in that Example, but using the current values.

Eq. (*a*): $I_3 = I_1 + I_2$; Eq. (*b*): $-34I_1 + 45 - 48I_3 = 0$

Eq. (*c*): $-34I_1 + 19I_2 - 75 = 0$ Eq. (*d*): $I_2 = \dfrac{75 + 34I_1}{19} = 3.95 + 1.79I_1$

Eq. (*e*): $I_3 = \dfrac{45 - 34I_1}{48} = 0.938 - 0.708I_1$

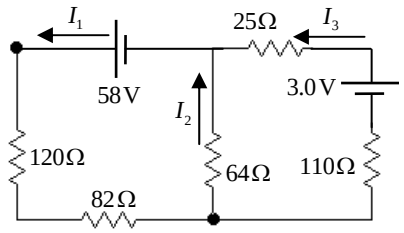
$$I_3 = I_1 + I_2 \rightarrow 0.938 - 0.708I_1 = I_1 + 3.95 + 1.79I_1 \rightarrow I_1 = -0.861\,\text{A}$$
$$I_2 = 3.95 + 1.79I_1 = 2.41\,\text{A} \;;\; I_3 = 0.938 - 0.708I_1 = 1.55\,\text{A}$$

(*a*) To find the potential difference between points a and d, start at point a and add each individual potential difference until reaching point d. The simplest way to do this is along the top branch.

$$V_{ad} = V_d - V_a = -I_1(34\,\Omega) = -(-0.861\,\text{A})(34\,\Omega) = 29.27\,\text{V} \approx \boxed{29\,\text{V}}$$

Slight differences will be obtained in the final answer depending on the branch used, due to rounding. For example, using the bottom branch, we get the following.

$$V_{ad} = V_d - V_a = \mathscr{E}_1 - I_2(19\,\Omega) = 75\,\text{V} - (2.41\,\text{A})(19\,\Omega) = 29.21\,\text{V} \approx 29\,\text{V}$$



(*b*) For the 75-V battery, the terminal voltage is the potential difference from point g to point e. For the 45-V battery, the terminal voltage is the potential difference from point d to point b.

75 V battery: $V_{\text{terminal}} = \mathscr{E}_1 - I_2 r = 75\,\text{V} - (2.41\,\text{A})(1.0\,\Omega) = \boxed{73\,\text{V}}$

45 V battery: $V_{\text{terminal}} = \mathscr{E}_2 - I_3 r = 45\,\text{V} - (1.55\,\text{A})(1.0\,\Omega) = \boxed{43\,\text{V}}$

32. There are three currents involved, and so there must be three independent equations to determine those three currents. One comes from Kirchhoff's junction rule applied to the junction of the three branches at the top center of the circuit.

$$I_1 = I_2 + I_3$$

Another equation comes from Kirchhoff's loop rule applied to the left loop, starting at the negative terminal of the battery and progressing counterclockwise.

$$58\,\text{V} - I_1(120\,\Omega) - I_1(82\,\Omega) - I_2(64\,\Omega) = 0 \;\rightarrow\; 58 = 202I_1 + 64I_2$$

The final equation comes from Kirchhoff's loop rule applied to the right loop, starting at the negative terminal of the battery and progressing counterclockwise.

$$3.0\,\text{V} - I_3(25\,\Omega) + I_2(64\,\Omega) - I_3(110\,\Omega) = 0 \;\rightarrow\; 3 = -64I_2 + 135I_3$$

Substitute $I_1 = I_2 + I_3$ into the left loop equation, so that there are two equations with two unknowns.

$$58 = 202(I_2 + I_3) + 64I_2 = 266I_2 + 202I_3$$

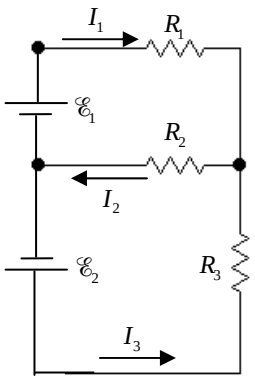
Solve the right loop equation for I_2 and substitute into the left loop equation, resulting in an equation with only one unknown, which can be solved.

$$3 = -64I_2 + 135I_3 \;\rightarrow\; I_2 = \frac{135I_3 - 3}{64} \;;\; 58 = 266I_2 + 202I_3 = 266\left(\frac{135I_3 - 3}{64}\right) + 202I_3 \;\rightarrow$$

$$I_3 = 0.09235\,\text{A} \;;\; I_2 = \frac{135I_3 - 3}{64} = 0.1479\,\text{A} \;;\; I_1 = I_2 + I_3 = 0.24025\,\text{A}$$

The current in each resistor is as follows:

120 Ω: 0.24 A	82 Ω: 0.24 A	64 Ω: 0.15 A	25 Ω: 0.092 A	110 Ω: 0.092 A



33. Because there are no resistors in the bottom branch, it is possible to write Kirchhoff loop equations that only have one current term, making them easier to solve. To find the current through R_1, go around the outer loop counterclockwise, starting at the lower left corner.

$$V_3 - I_1R_1 + V_1 = 0 \;\rightarrow\; I_1 = \frac{V_3 + V_1}{R_1} = \frac{6.0\,\text{V} + 9.0\,\text{V}}{22\,\Omega} = \boxed{0.68\,\text{A, left}}$$

To find the current through R_2, go around the lower loop counterclockwise, starting at the lower left corner.

$$V_3 - I_2R_2 = 0 \;\rightarrow\; I_2 = \frac{V_3}{R_2} = \frac{6.0\,\text{V}}{18\,\Omega} = \boxed{0.33\,\text{A, left}}$$

34. (a) There are three currents involved, and so there must be three independent equations to determine those three currents. One comes from Kirchhoff's junction rule applied to the junction of the three branches on the right of the circuit.

$$I_2 = I_1 + I_3 \;\rightarrow\; I_1 = I_2 - I_3$$

Another equation comes from Kirchhoff's loop rule applied to the top loop, starting at the negative terminal of the battery and progressing clockwise.

$$\mathscr{E}_1 - I_1R_1 - I_2R_2 = 0 \;\rightarrow\; 9 = 25I_1 + 48I_2$$

The final equation comes from Kirchhoff's loop rule applied to the bottom loop, starting at the negative terminal of the battery and

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

progressing counterclockwise.

$$\mathscr{E}_2 - I_3R_3 - I_2R_2 = 0 \;\rightarrow\; 12 = 35I_3 + 48I_2$$

Substitute $I_1 = I_2 - I_3$ into the top loop equation, so that there are two equations with two unknowns.

$$9 = 25I_1 + 48I_2 = 25\left(I_2 - I_3\right) + 48I_2 = 73I_2 - 25I_3 \;;\; 12 = 35I_3 + 48I_2$$

Solve the bottom loop equation for I_2 and substitute into the top loop equation, resulting in an equation with only one unknown, which can be solved.

$$12 = 35I_3 + 48I_2 \;\rightarrow\; I_2 = \frac{12 - 35I_3}{48}$$

$$9 = 73I_2 - 25I_3 = 73\left(\frac{12 - 35I_3}{48}\right) - 25I_3 \;\rightarrow\; 432 = 876 - 2555I_3 - 1200I_3 \;\rightarrow$$

$$I_3 = \frac{444}{3755} = 0.1182\,\text{A} \approx \boxed{0.12\,\text{A , up}} \;;\; I_2 = \frac{12 - 35I_3}{48} = 0.1638\,\text{A} \approx \boxed{0.16\,\text{A , left}}$$

$$I_1 = I_2 - I_3 = 0.0456\,\text{A} \approx \boxed{0.046\,\text{A , right}}$$

(*b*) We can include the internal resistances simply by adding $1.0\,\Omega$ to R_1 and R_3. So let $R_1 = 26\,\Omega$ and let $R_3 = 36\,\Omega$. Now re-work the problem exactly as in part (*a*).

$$I_2 = I_1 + I_3 \;\rightarrow\; I_1 = I_2 - I_3$$

$$\mathscr{E}_1 - I_1R_1 - I_2R_2 = 0 \;\rightarrow\; 9 = 26I_1 + 48I_2$$

$$\mathscr{E}_2 - I_3R_3 - I_2R_2 = 0 \;\rightarrow\; 12 = 36I_3 + 48I_2$$

$$9 = 26I_1 + 48I_2 = 26\left(I_2 - I_3\right) + 48I_2 = 74I_2 - 26I_3 \;;\; 12 = 36I_3 + 48I_2$$

$$12 = 36I_3 + 48I_2 \;\rightarrow\; I_2 = \frac{12 - 36I_3}{48} = \frac{1 - 3I_3}{4}$$

$$9 = 74I_2 - 26I_3 = 74\left(\frac{1 - 3I_3}{4}\right) - 26I_3 \;\rightarrow\; 36 = 74 - 222I_3 - 104I_3 \;\rightarrow$$

$$I_3 = \frac{38}{326} = 0.1166\,\text{A} \approx \boxed{0.12\,\text{A , up}} \;;\; I_2 = \frac{1 - 3I_3}{4} = 0.1626\,\text{A} \approx \boxed{0.16\,\text{A, left}}$$

$$I_1 = I_2 - I_3 = \boxed{0.046\,\text{A , right}}$$

The currents are unchanged to 2 significant figures by the inclusion of the internal resistances.

35. We are to find the ratio of the power used when the resistors are in series, to the power used when the resistors are in parallel. The voltage is the same in both cases. Use Eq. 25-7b, along with the definitions of series and parallel equivalent resistance.

$$R_{\text{series}} = R_1 + R_2 + \cdots R_n = nR \;;\; R_{\text{parallel}} = \left(\frac{1}{R_1} + \frac{1}{R_2} + \cdots \frac{1}{R_{\text{n}}}\right)^{-1} = \left(\frac{n}{R}\right)^{-1} = \frac{R}{n}$$

$$\frac{P_{\text{series}}}{P_{\text{parallel}}} = \frac{V^2/R_{\text{series}}}{V^2/R_{\text{parallel}}} = \frac{R_{\text{parallel}}}{R_{\text{series}}} = \frac{R/n}{nR} = \boxed{\frac{1}{n^2}}$$

36. (*a*) Since there are three currents to determine, there must be three independent equations to determine those three currents. One comes from Kirchhoff's junction rule applied to the junction near the negative terminal of the middle battery.

$$I_1 = I_2 + I_3$$

Another equation comes from Kirchhoff's loop rule applied to the top loop, starting at the negative terminal of the middle battery, and progressing counterclockwise. We add series resistances.

$$12.0\,\text{V} - I_2(12\,\Omega) + 12.0\,\text{V} - I_1(35\,\Omega) = 0 \;\rightarrow\; 24 = 35I_1 + 12I_2$$

The final equation comes from Kirchhoff's loop rule applied to the bottom loop, starting at the negative terminal of the middle battery, and progressing clockwise.

$$12.0\,\text{V} - I_2(12\,\Omega) - 6.0\,\text{V} + I_3(34\,\Omega) = 0 \;\rightarrow\; 6 = 12I_2 - 34I_3$$

Substitute $I_1 = I_2 + I_3$ into the top loop equation, so that there are two equations with two unknowns.

$$24 = 35I_1 + 12I_2 = 35(I_2 + I_3) + 12I_2 = 47I_2 + 35I_3$$

Solve the bottom loop equation for I_2 and substitute into the top loop equation, resulting in an equation with only one unknown, which can be solved for I_3.

$$6 = 12I_2 - 34I_3 \;\rightarrow\; I_2 = \frac{6 + 34I_3}{12} \;;\; 24 = 47I_2 + 35I_3 = 47\left(\frac{6 + 34I_3}{12}\right) + 35I_3 \;\rightarrow$$

$$I_3 = \boxed{2.97\,\text{mA}} \;;\; I_2 = \frac{6 + 34I_3}{12} = \boxed{0.508\,\text{A}} \;;\; I_1 = I_2 + I_3 = \boxed{0.511\,\text{A}}$$

(*b*) The terminal voltage of the 6.0-V battery is $6.0\,\text{V} - I_3 r = 6.0\,\text{V} - (2.97\times10^{-3}\,\text{A})(1.0\,\Omega)$

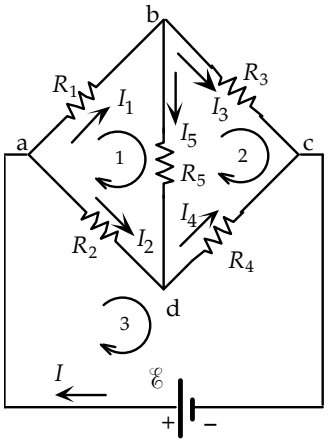
$= 5.997\,\text{V} \approx \boxed{6.0\,\text{V}}$.

37. This problem is the same as Problem 36, except the total resistance in the top branch is now $23\,\Omega$ instead of $35\,\Omega$. We simply reproduce the adjusted equations here without the prose.

$$I_1 = I_2 + I_3$$

$$12.0\,\text{V} - I_2(12\,\Omega) + 12.0\,\text{V} - I_1(23\,\Omega) = 0 \;\rightarrow\; 24 = 23I_1 + 12I_2$$

$$12.0\,\text{V} - I_2(12\,\Omega) - 6.0\,\text{V} + I_3(34\,\Omega) = 0 \;\rightarrow\; 6 = 12I_2 - 34I_3$$



$$24 = 23I_1 + 12I_2 = 23(I_2 + I_3) + 12I_2 = 35I_2 + 23I_3$$

$$6 = 12I_2 - 34I_3 \;\rightarrow\; I_2 = \frac{6 + 34I_3}{12} \;;\; 24 = 35I_2 + 23I_3 = 35\left(\frac{6 + 34I_3}{12}\right) + 23I_3 \;\rightarrow$$

$$I_3 = 0.0532\,\text{A} \;;\; I_2 = \frac{6 + 34I_3}{12} = 0.6508\,\text{A} \;;\; I_1 = I_2 + I_3 = 0.704\ \text{A} \approx \boxed{0.70\,\text{A}}$$

38. The circuit diagram has been labeled with six different currents. We apply the junction rule to junctions a, b, and c. We apply the loop rule to the three loops labeled in the diagram.

1) $I = I_1 + I_2$; 2) $I_1 = I_3 + I_5$; 3) $I_3 + I_4 = I$

4) $-I_1R_1 - I_5R_5 + I_2R_2 = 0$; 5) $-I_3R_3 + I_4R_4 + I_5R_5 = 0$

6) $\mathscr{E} - I_2R_2 - I_4R_4 = 0$

Eliminate I using equations 1) and 3).

1) $I_3 + I_4 = I_1 + I_2$; 2) $I_1 = I_3 + I_5$

4) $-I_1R_1 - I_5R_5 + I_2R_2 = 0$; 5) $-I_3R_3 + I_4R_4 + I_5R_5 = 0$

6) $\mathscr{E} - I_2R_2 - I_4R_4 = 0$

Eliminate I_1 using equation 2.

1) $I_3 + I_4 = I_3 + I_5 + I_2 \rightarrow I_4 = I_5 + I_2$

4) $-(I_3 + I_5)R_1 - I_5R_5 + I_2R_2 = 0 \rightarrow -I_3R_1 - I_5(R_1 + R_5) + I_2R_2 = 0$

5) $-I_3R_3 + I_4R_4 + I_5R_5 = 0$

6) $\mathscr{E} - I_2R_2 - I_4R_4 = 0$

Eliminate I_4 using equation 1.

4) $-I_3R_1 - I_5(R_1 + R_5) + I_2R_2 = 0$

5) $-I_3R_3 + (I_5 + I_2)R_4 + I_5R_5 = 0 \rightarrow -I_3R_3 + I_5(R_4 + R_5) + I_2R_4 = 0$

6) $\mathscr{E} - I_2R_2 - (I_5 + I_2)R_4 = 0 \rightarrow \mathscr{E} - I_2(R_2 + R_4) - I_5R_4 = 0$

Eliminate I_2 using equation 4: $I_2 = \dfrac{1}{R_2}\left[I_3R_1 + I_5(R_1 + R_5)\right]$.

$$5)\ -I_3R_3 + I_5(R_4 + R_5) + \frac{1}{R_2}\left[I_3R_1 + I_5(R_1 + R_5)\right]R_4 = 0 \rightarrow$$

$$I_3(R_1R_4 - R_2R_3) + I_5(R_2R_4 + R_2R_5 + R_1R_4 + R_5R_4) = 0$$

$$6)\ \mathscr{E} - \frac{1}{R_2}\left[I_3R_1 + I_5(R_1 + R_5)\right](R_2 + R_4) - I_5R_4 = 0 \rightarrow$$

$$\mathscr{E}R_2 - I_3R_1(R_2 + R_4) - I_5(R_1R_2 + R_1R_4 + R_5R_2 + R_5R_4 + R_2R_4) = 0$$

Eliminate I_3 using equation 5: $I_3 = -I_5\dfrac{(R_2R_4 + R_2R_5 + R_1R_4 + R_5R_4)}{(R_1R_4 - R_2R_3)}$

$$\mathscr{E}R_2 + \left[I_5\frac{(R_2R_4 + R_2R_5 + R_1R_4 + R_5R_4)}{(R_1R_4 - R_2R_3)}\right]R_1(R_2 + R_4) - I_5(R_1R_2 + R_1R_4 + R_5R_2 + R_5R_4 + R_2R_4) = 0$$

$$\mathscr{E} = -\frac{I_5}{R_2}\left\{\left[\frac{(R_2R_4 + R_2R_5 + R_1R_4 + R_5R_4)}{(R_1R_4 - R_2R_3)}\right]R_1(R_2 + R_4) - (R_1R_2 + R_1R_4 + R_5R_2 + R_5R_4 + R_2R_4)\right\}$$

$$= -\frac{I_5}{25\Omega}\left\{\left[\frac{(25\Omega)(14\Omega) + (25\Omega)(15\Omega) + (22\Omega)(14\Omega) + (15\Omega)(14\Omega)}{(22\Omega)(14\Omega) - (25\Omega)(12\Omega)}\right](22\Omega)(25\Omega + 14\Omega)\right.$$
$$\left. -\left[(22\Omega)(25\Omega) + (22)(14) + (15\Omega)(25\Omega) + (15\Omega)(14\Omega) + (25\Omega)(14\Omega)\right]\right\}$$

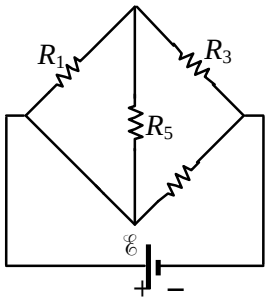
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= -I_5(5261\Omega) \;\rightarrow\; I_5 = -\frac{6.0\,\text{V}}{5261\Omega} = -1.140\,\text{mA}\ (\text{upwards})$$

$$I_3 = -I_5\frac{(R_2R_4 + R_2R_5 + R_1R_4 + R_5R_4)}{(R_1R_4 - R_2R_3)}$$

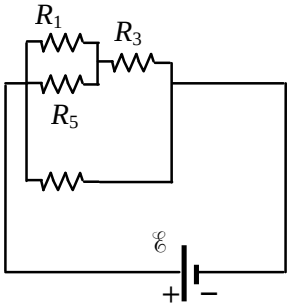
$$= -(-1.140\,\text{mA})\frac{(25\Omega)(14\Omega)+(25\Omega)(15\Omega)+(22\Omega)(14\Omega)+(15\Omega)(14\Omega)}{(22\Omega)(14\Omega)-(25\Omega)(12\Omega)} = 0.1771\,\text{A}$$

$$I_2 = \frac{1}{R_2}\left[I_3R_1 + I_5(R_1+R_5)\right] = \frac{1}{25\Omega}\left[(0.1771\,\text{A})(22\Omega)+(-0.00114\,\text{A})(37\Omega)\right] = 0.1542\,\text{A}$$



$$I_4 = I_5 + I_2 = -0.00114\,\text{A} + 0.1542\,\text{A} = 0.1531\,\text{A}$$

$$I_1 = I_3 + I_5 = 0.1771\,\text{A} - 0.00114\,\text{A} = 0.1760\,\text{A}$$



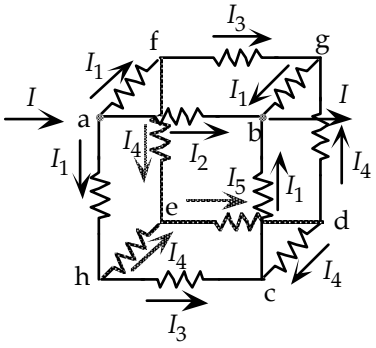
We keep an extra significant figure to show the slight difference in the currents.

$$\boxed{I_{22\Omega} = 0.176\text{A} \quad I_{25\Omega} = 0.154\,\text{A} \quad I_{12\Omega} = 0.177\,\text{A} \quad I_{14\Omega} = 0.153\,\text{A} \quad I_{15\Omega} = 0.001\,\text{A, upwards}}$$

39. The circuit diagram from Problem 38 is reproduced, with $R_2 = 0$. This circuit can now be simplified significantly. Resistors R_1 and R_5 are in parallel. Call that combination R_{15}. That combination is in series with R_3. Call that combination R_{153}. That combination is in parallel with R_4. See the second diagram. We calculate the equivalent resistance R_{153}, use that to find the current through the top branch in the second diagram, and then use that current to find the current through R_5.

$$R_{153} = \left(\frac{1}{R_1}+\frac{1}{R_5}\right)^{-1} + R_3 = \left(\frac{1}{22\Omega}+\frac{1}{15\Omega}\right)^{-1} + 12\Omega = 20.92\Omega$$

Use the loop rule for the outside loop to find the current in the top branch.



$$\mathscr{E} - I_{153}R_{153} = 0 \;\rightarrow\; I_{153} = \frac{\mathscr{E}}{R_{153}} = \frac{6.0\,\text{V}}{20.92\Omega} = 0.2868\,\text{A}$$

This current is the sum of the currents in R_1 and R_5. Since those two resistors are in parallel, the voltage across them must be the same.

$$V_1 = V_5 \;\rightarrow\; I_1R_1 = I_5R_5 \;\rightarrow\; (I_{153} - I_5)R_1 = I_5R_5 \;\rightarrow$$

$$I_5 = I_{153}\frac{R_1}{(R_5+R_1)} = (0.2868\,\text{A})\frac{22\Omega}{37\Omega} = \boxed{0.17\,\text{A}}$$

40. (*a*) As shown in the diagram, we use symmetry to reduce the number of independent currents to six. Using Kirchhoff's junction rule, we write equations for junctions a, c, and d. We then use Kirchhoff's loop rule to write the loop equations for loops afgba, hedch, and aba (through the voltage source).

$$I = 2I_1 + I_2 \;\; [1] \;;\; I_3 + I_4 = I_1 \;\; [2] \;;\; I_5 = 2I_4 \;\; [3]$$

$$0 = -2I_1R - I_3R + I_2R \;\; [4] \;;\; 0 = -2I_4R - I_5R + I_3R \;\; [5]$$

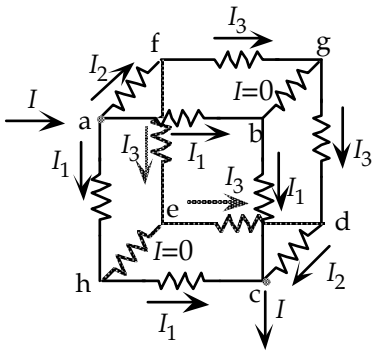
$$0 = \mathscr{E} - I_2R \;\; [6]$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

We have six equations with six unknown currents. We use the method of substitution to reduce the equations to a single equation relating the emf from the power source to the current through the power source. This resulting ratio is the effective resistance between points a and b. We insert Eqs. [2], [3], and [6] into the other three equations to eliminate I_1, I_2, and I_5.

$$I = 2\left(I_3 + I_4\right) + \frac{\mathscr{E}}{R} = 2I_3 + 2I_4 + \frac{\mathscr{E}}{R} \qquad [1^*]$$

$$0 = -2\left(I_3 + I_4\right)R - I_3R + \frac{\mathscr{E}}{R}R = -2I_4R - 3I_3R + \mathscr{E} \qquad [4^*]$$



$$0 = -2I_4R - 2I_4R + I_3R = -4I_4R + I_3R \qquad [5^*]$$

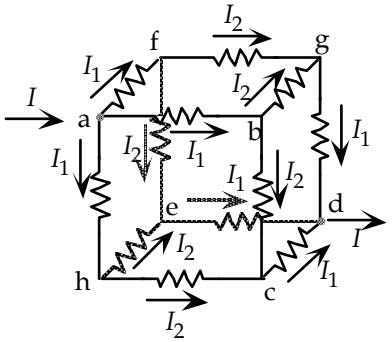
We solve Eq. [5*] for I_3 and insert that into Eq. [4*]. We then insert the two results into Eq. [1*] and solve for the effective resistance.

$$I_3 = 4I_4 \;\; ; \;\; 0 = -2I_4R - 3\left(4I_4\right)R + \mathscr{E} \rightarrow I_4 = \frac{\mathscr{E}}{14R}$$

$$I = 2\left(4I_4\right) + 2I_4 + \frac{\mathscr{E}}{R} = 10I_4 + \frac{\mathscr{E}}{R} = \frac{10\mathscr{E}}{14R} + \frac{\mathscr{E}}{R} = \frac{24\mathscr{E}}{14R} = \frac{12\mathscr{E}}{7R} \;\; \rightarrow \;\; R_{\text{eq}} = \frac{\mathscr{E}}{I} = \boxed{\tfrac{7}{12}R}$$

(*b*) As shown in the diagram, we use symmetry to reduce the number of currents to four. We use Kirchhoff's junction rule at junctions a and d and the loop rule around loops abca (through the voltage source) and afgdcha. This results in four equations with four unknowns. We solve these equations for the ratio of the voltage source to current *I*, to obtain the effective resistance.

$$I = 2I_1 + I_2 \;\; [1] \qquad ; \;\; 2I_3 = I_2 \;\; [2]$$



$$0 = -2I_2R + \mathscr{E} \;\; [3] \;\; ; \;\; 0 = -2I_2R - 2I_3R + 2I_1R \;\; [4]$$

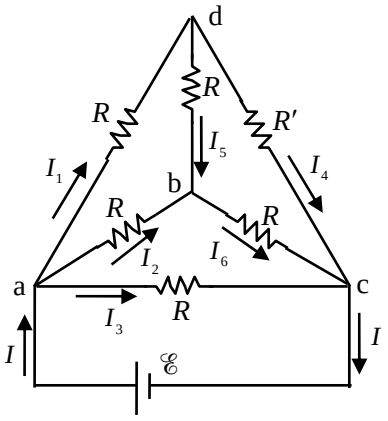
We solve Eq. [3] for I_2 and Eq. [2] for I_3. These results are inserted into Eq. [4] to determine I_1. Using these results and Eq. [1] we solve for the effective resistance.

$$I_2 = \frac{\mathscr{E}}{2R} \;\; ; \;\; I_3 = \frac{I_2}{2} = \frac{\mathscr{E}}{4R} \;\; ; \;\; I_1 = I_2 + I_3 = \frac{\mathscr{E}}{2R} + \frac{\mathscr{E}}{4R} = \frac{3\mathscr{E}}{4R}$$

$$I = 2I_1 + I_2 = 2\left(\frac{3\mathscr{E}}{4R}\right) + \frac{\mathscr{E}}{2R} = \frac{2\mathscr{E}}{R} \;\; ; \;\; R_{\text{eq}} = \frac{\mathscr{E}}{I} = \boxed{\tfrac{1}{2}R}$$

(*c*) As shown in the diagram, we again use symmetry to reduce the number of currents to three. We use Kirchhoff's junction rule at points a and b and the loop rule around the loop abgda (through the power source) to write three equations for the three unknown currents. We solve these equations for the ratio of the emf to the current through the emf (I) to calculate the effective resistance.

$$I = 3I_1 \;\; [1] \;\; ; \;\; I_1 = 2I_2 \;\; [2]$$



$$0 = -2I_1R - I_2R + \mathscr{E} \;\; [3]$$

We insert Eq. [2] into Eq. [3] and solve for I_1. Inserting I_1 into Eq. [1] enables us to solve for the effective resistance.

$$0 = -2I_1R - \tfrac{1}{2}I_1R + \mathscr{E} \rightarrow I_1 = \frac{2\mathscr{E}}{5R} \;\; ; \;\; I = 3I_1 = \frac{6\mathscr{E}}{5R} \rightarrow R_{\text{eq}} = \frac{\mathscr{E}}{I} = \boxed{\tfrac{5}{6}R}$$

41. (*a*) To find the equivalent resistance between points a and c, apply a voltage between points a and c, find the current that flows from the voltage source, and then calculate $R_{eq} = \mathscr{E}/I$.

There is no symmetry to exploit.

(Bottom Loop) 1) $\mathscr{E} - RI_3 = 0$

(a - d - b) 2) $-RI_1 - RI_5 + RI_2 = 0$

(a - b - c) 3) $-RI_2 - RI_6 + RI_3 = 0$

(d - b - c) 4) $-RI_5 - RI_6 + R'I_4 = 0$

(junction a) 5) $I = I_1 + I_2 + I_3$

(junction d) 6) $I_1 = I_4 + I_5$

(junction b) 7) $I_2 + I_5 = I_6$

From Eq. 1, substitute $I_3 = \mathscr{E}/R$.

2) $-RI_1 - RI_5 + RI_2 = 0 \rightarrow I_1 + I_5 = I_2$

3) $-RI_2 - RI_6 + R\dfrac{\mathscr{E}}{R} = 0 \rightarrow I_2 + I_6 = \dfrac{\mathscr{E}}{R}$

4) $-RI_5 - RI_6 + R'I_4 = 0 \rightarrow R(I_5 + I_6) = R'I_4$

5) $I = I_1 + I_2 + \dfrac{\mathscr{E}}{R}$; 6) $I_1 = I_4 + I_5$; 7) $I_2 + I_5 = I_6$

From Eq. 7, substitute $I_6 = I_2 + I_5$

2) $I_1 + I_5 = I_2$; 3) $I_2 + I_2 + I_5 = \dfrac{\mathscr{E}}{R} \rightarrow 2I_2 + I_5 = \dfrac{\mathscr{E}}{R}$

4) $R(2I_5 + I_2) = R'I_4$; 5) $I = I_1 + I_2 + \dfrac{\mathscr{E}}{R}$; 6) $I_1 = I_4 + I_5$

From Eq. 6, substitute $I_1 = I_4 + I_5 \rightarrow I_5 = I_1 - I_4$

2) $2I_1 - I_4 = I_2$; 3) $2I_2 + I_1 - I_4 = \dfrac{\mathscr{E}}{R}$

4) $R(2I_1 - 2I_4 + I_2) = R'I_4$; 5) $I = I_1 + I_2 + \dfrac{\mathscr{E}}{R}$

From Eq. 2, substitute $2I_1 - I_4 = I_2 \rightarrow I_4 = 2I_1 - I_2$

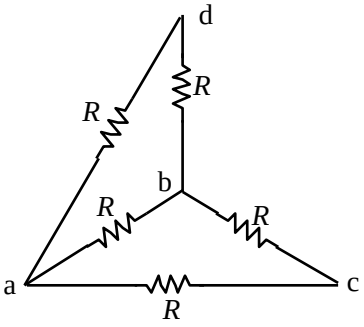
3) $2I_2 + I_1 - (2I_1 - I_2) = \dfrac{\mathscr{E}}{R} \rightarrow 3I_2 - I_1 = \dfrac{\mathscr{E}}{R}$

4) $R(2I_1 - 2(2I_1 - I_2) + I_2) = R'(2I_1 - I_2) \rightarrow R(3I_2 - 2I_1) = R'(2I_1 - I_2)$

5) $I = I_1 + I_2 + \dfrac{\mathscr{E}}{R}$

From Eq. 3, substitute $3I_2 - I_1 = \dfrac{\mathscr{E}}{R} \rightarrow I_1 = 3I_2 - \dfrac{\mathscr{E}}{R}$

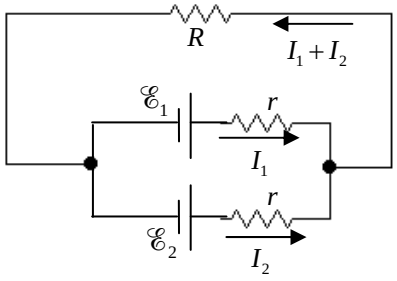
4) $R\left(3I_2 - 2\left(3I_2 - \dfrac{\mathscr{E}}{R}\right)\right) = R'\left(2\left(3I_2 - \dfrac{\mathscr{E}}{R}\right) - I_2\right) \rightarrow R\left(-3I_2 + 2\dfrac{\mathscr{E}}{R}\right) = R'\left(5I_2 - 2\dfrac{\mathscr{E}}{R}\right)$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5) $I = 3I_2 - \dfrac{\mathscr{E}}{R} + I_2 + \dfrac{\mathscr{E}}{R} \;\rightarrow\; I = 4I_2$

From Eq. 5, substitute $I_2 = \frac{1}{4}I$



4) $R\left(-3\left(\frac{1}{4}I\right) + 2\dfrac{\mathscr{E}}{R}\right) = R'\left(5\left(\frac{1}{4}I\right) - 2\dfrac{\mathscr{E}}{R}\right) \;\rightarrow\; \dfrac{\mathscr{E}}{I} = \boxed{R_{\text{eq}} = \dfrac{R(5R'+3R)}{8(R+R')}}$

(*b*) In this case, apply a voltage between points a and b. Now there is symmetry. In this case no current would flow through resistor R', and so that branch can be eliminated from the circuit. See the adjusted diagram. Now the upper left two resistors (from a to d to b) are in series, and the lower right two resistors (from a to c to b) are in series. These two combinations are in parallel with each other, and with the resistor between a and b. The equivalent resistance is now relatively simple to calculate.

$$R_{\text{eq}} = \left(\frac{1}{2R} + \frac{1}{R} + \frac{1}{2R}\right)^{-1} = \left(\frac{4}{2R}\right)^{-1} = \boxed{\tfrac{1}{2}R}$$

42. Define I_1 to be the current to the right through the 2.00 V battery $(\mathscr{E}_1)$, and I_2 to be the current to the right through the 3.00 V battery $(\mathscr{E}_2)$. At the junction, they combine to give current $I = I_1 + I_2$ to the left through the top branch. Apply Kirchhoff's loop rule first to the upper loop, and then to the outer loop, and solve for the currents.

$$\mathscr{E}_1 - I_1 r - (I_1 + I_2)R = 0 \;\rightarrow\; \mathscr{E}_1 - (R+r)I_1 - RI_2 = 0$$
$$\mathscr{E}_2 - I_2 r - (I_1 + I_2)R = 0 \;\rightarrow\; \mathscr{E}_2 - RI_1 - (R+r)I_2 = 0$$

Solve the first equation for I_2 and substitute into the second equation to solve for I_1.

$$\mathscr{E}_1 - (R+r)I_1 - RI_2 = 0 \;\rightarrow\; I_2 = \frac{\mathscr{E}_1 - (R+r)I_1}{R} = \frac{2.00 - 4.450I_1}{4.00} = 0.500 - 1.1125I_1$$
$$\mathscr{E}_2 - RI_1 - (R+r)I_2 = 3.00\,\text{V} - (4.00\,\Omega)I_1 - (4.45\,\Omega)(0.500 - 1.1125I_1) = 0 \;\rightarrow$$
$$I_1 = -0.815\,\text{A} \;;\; I_2 = 0.500 - 1.1125I_1 = 1.407\,\text{A}$$

The voltage across *R* is its resistance times $I = I_1 + I_2$.

$$V_R = R(I_1 + I_2) = (4.00\,\Omega)(-0.815\,\text{A} + 1.407\,\text{A}) = 2.368\,\text{V} \approx \boxed{2.37\,\text{V}}$$

Note that the top battery is being charged – the current is flowing through it from positive to negative.

43. We estimate the time between cycles of the wipers to be from 1 second to 15 seconds. We take these times as the time constant of the *RC* combination.

$$\tau = RC \;\rightarrow\; R_{1\text{s}} = \frac{\tau}{C} = \frac{1\text{s}}{1\times10^{-6}\,\text{F}} = 10^6\,\Omega \;;\; R_{1\text{s}} = \frac{\tau}{C} = \frac{15\text{s}}{1\times10^{-6}\,\text{F}} = 15\times10^6\,\Omega$$

So we estimate the range of resistance to be $\boxed{1\,\text{M}\Omega \;-\; 15\,\text{M}\Omega}$.

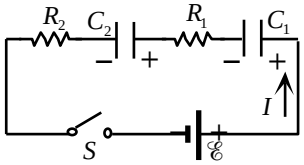
44. (*a*) From Eq. 26-7 the product *RC* is equal to the time constant.



$$\tau = RC \;\rightarrow\; C = \frac{\tau}{R} = \frac{24.0\times10^{-6}\,\text{s}}{15.0\times10^{3}\,\Omega} = \boxed{1.60\times10^{-9}\,\text{F}}$$

(*b*) Since the battery has an EMF of 24.0 V, if the voltage across the resistor is 16.0 V, the voltage across the capacitor will be 8.0 V as it charges. Use the expression for the voltage across a charging capacitor.

$$V_C = \mathscr{E}\left(1-e^{-t/\tau}\right) \;\rightarrow\; e^{-t/\tau} = \left(1-\frac{V_C}{\mathscr{E}}\right) \;\rightarrow\; -\frac{t}{\tau} = \ln\left(1-\frac{V_C}{\mathscr{E}}\right) \;\rightarrow$$

$$t = -\tau\ln\left(1-\frac{V_C}{\mathscr{E}}\right) = -\left(24.0\times10^{-6}\,\text{s}\right)\ln\left(1-\frac{8.0\,\text{V}}{24.0\,\text{V}}\right) = \boxed{9.73\times10^{-6}\,\text{s}}$$

45. The current for a capacitor-charging circuit is given by Eq. 26-8, with *R* the equivalent series resistance and *C* the equivalent series capacitance.

$$I = \frac{\mathscr{E}}{R_{\text{eq}}}e^{-\left(\frac{t}{R_{\text{eq}}C_{\text{eq}}}\right)} \;\rightarrow$$

$$t = -R_{\text{eq}}C_{\text{eq}}\ln\left(\frac{IR_{\text{eq}}}{\mathscr{E}}\right) = -\left(R_1+R_2\right)\left(\frac{C_1C_2}{C_1+C_2}\right)\ln\left[\frac{I\left(R_1+R_2\right)}{\mathscr{E}}\right]$$

$$= -\left(4400\,\Omega\right)\left[\frac{\left(3.8\times10^{-6}\,\text{F}\right)^2}{7.6\times10^{-6}\,\text{F}}\right]\ln\left[\frac{\left(1.50\times10^{-3}\,\text{A}\right)\left(4400\,\Omega\right)}{\left(12.0\text{V}\right)}\right] = \boxed{5.0\times10^{-3}\,\text{s}}$$

46. Express the stored energy in terms of the charge on the capacitor, using Eq. 24-5. The charge on the capacitor is given by Eq. 26-6a.

$$U = \tfrac{1}{2}\frac{Q^2}{C} = \tfrac{1}{2}\frac{\left[C\mathscr{E}\left(1-e^{-t/\tau}\right)\right]^2}{C} = \tfrac{1}{2}C\mathscr{E}^2\left(1-e^{-t/\tau}\right)^2 = U_{\max}\left(1-e^{-t/\tau}\right)^2 \;;$$

$$U = 0.75U_{\max} \;\rightarrow\; U_{\max}\left(1-e^{-t/\tau}\right)^2 = 0.75U_{\max} \;\rightarrow\; \left(1-e^{-t/\tau}\right)^2 = 0.75 \;\rightarrow$$

$$t = -\tau\ln\left(1-\sqrt{0.75}\right) = \boxed{2.01\tau}$$

47. The capacitance is given by Eq. 24-8 and the resistance by Eq. 25-3. The capacitor plate separation *d* is the same as the resistor length ℓ. Calculate the time constant.

$$\tau = RC = \left(\frac{\rho d}{A}\right)\left(K\varepsilon_0\frac{A}{d}\right) = \boxed{\rho K\varepsilon_0} = \left(1.0\times10^{12}\,\Omega\bullet\text{m}\right)\left(5.0\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\bullet\text{m}^2\right) = \boxed{44\,\text{s}}$$

48. The voltage of the discharging capacitor is given by $V_C = V_0e^{-t/RC}$. The capacitor voltage is to be $0.0010V_0$.

$$V_C = V_0e^{-t/RC} \;\rightarrow\; 0.0010V_0 = V_0e^{-t/RC} \;\rightarrow\; 0.0010 = e^{-t/RC} \;\rightarrow\; \ln\left(0.010\right) = -\frac{t}{RC} \;\rightarrow$$

$$t = -RC\ln\left(0.010\right) = -\left(8.7\times10^{3}\,\Omega\right)\left(3.0\times10^{-6}\,\text{F}\right)\ln\left(0.0010\right) = \boxed{0.18\,\text{s}}$$

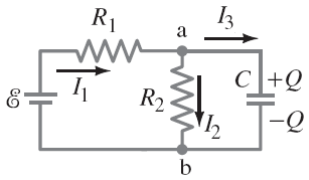
49. (*a*) At $t = 0$, the capacitor is uncharged and so there is no voltage difference across it. The capacitor is a "short," and so a simpler circuit can be drawn just by eliminating the capacitor. In this simpler circuit, the two resistors on the right are in parallel with each other, and then in series with the resistor by the switch. The current through the resistor by the switch splits equally when it reaches the junction of the parallel resistors.

$$R_{\text{eq}} = R + \left(\frac{1}{R} + \frac{1}{R}\right)^{-1} = \tfrac{3}{2}R \;\rightarrow\; I_1 = \frac{\mathscr{E}}{R_{\text{eq}}} = \frac{\mathscr{E}}{\frac{3}{2}R} = \boxed{\frac{2\mathscr{E}}{3R}}\,;\; I_2 = I_3 = \tfrac{1}{2}I_1 = \boxed{\frac{\mathscr{E}}{3R}}$$



(*b*) At $t = \infty$, the capacitor will be fully charged and there will be no current in the branch containing the capacitor, and so a simpler circuit can be drawn by eliminating that branch. In this simpler circuit, the two resistors are in series, and they both have the same current.

$$R_{\text{eq}} = R + R = 2R \;\rightarrow\; I_1 = I_2 = \frac{\mathscr{E}}{R_{\text{eq}}} = \boxed{\frac{\mathscr{E}}{2R}}\;;\; I_3 = \boxed{0}$$

(*c*) At $t = \infty$, since there is no current through the branch containing the capacitor, there is no potential drop across that resistor. Therefore the voltage difference across the capacitor equals the voltage difference across the resistor through which I_2 flows.

$$V_C = V_{R_2} = I_2 R = \left(\frac{\mathscr{E}}{2R}\right)R = \boxed{\tfrac{1}{2}\mathscr{E}}$$

50. (*a*) With the currents and junctions labeled as in the diagram, we use point a for the junction rule and the right and left loops for the loop rule. We set current I_3 equal to the derivative of the charge on the capacitor and combine the equations to obtain a single differential equation in terms of the capacitor charge. Solving this equation yields the charging time constant.

$$I_1 = I_2 + I_3 \;\; [1]\;;\; \mathscr{E} - I_1R_1 - I_2R_2 = 0 \;\; [2]\;;\; -\frac{Q}{C} + I_2R_2 = 0 \;\; [3]$$

We use Eq. [1] to eliminate I_1 in Eq. [2]. Then we use Eq. [3] to eliminate I_2 from Eq. [2].

$$0 = \mathscr{E} - (I_2 + I_3)R_1 - I_2R_2 \;;\; 0 = \mathscr{E} - I_2(R_1 + R_2) - I_3R_1 \;;\; 0 = \mathscr{E} - \left(\frac{Q}{R_2C}\right)(R_1 + R_2) - I_3R_1$$

We set I_3 as the derivative of the charge on the capacitor and solve the differential equation by separation of variables.

$$0 = \mathscr{E} - \left(\frac{Q}{R_2C}\right)(R_1 + R_2) - \frac{dQ}{dt}R_1 \;\rightarrow\; \int_0^Q \frac{dQ'}{Q' - \left(\frac{R_2C\mathscr{E}}{R_1 + R_2}\right)} = \int_0^t \frac{-(R_1 + R_2)}{R_1R_2C}\,dt' \;\rightarrow$$

$$\ln\left[Q' - \left(\frac{R_2C\mathscr{E}}{R_1 + R_2}\right)\right]_0^Q = -\frac{(R_1 + R_2)}{R_1R_2C}t'\Big|_0^t \;\rightarrow\; \ln\left[\frac{Q - \left(\frac{R_2C\mathscr{E}}{R_1 + R_2}\right)}{\left(\frac{R_2C\mathscr{E}}{R_1 + R_2}\right)}\right] = -\frac{(R_1 + R_2)}{R_1R_2C}t \;\rightarrow$$

$$Q = \frac{R_2C\mathscr{E}}{R_1 + R_2}\left(1 - e^{-\frac{(R_1 + R_2)}{R_1R_2C}t}\right)$$

From the exponential term we obtain the time constant, $\tau = \boxed{\dfrac{R_1R_2C}{R_1 + R_2}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We obtain the maximum charge on the capacitor by taking the limit as time goes to infinity.

$$Q_{\max} = \lim_{t\to\infty} \frac{R_2 C\mathscr{E}}{R_1 + R_2}\left(1 - e^{-\frac{(R_1+R_2)}{R_1 R_2 C}t}\right) = \boxed{\frac{R_2 C\mathscr{E}}{R_1 + R_2}}$$

51. (*a*) With the switch open, the resistors are in series with each other, and so have the same current. Apply the loop rule clockwise around the left loop, starting at the negative terminal of the source, to find the current.

$$V - IR_1 - IR_2 = 0 \;\rightarrow\; I = \frac{V}{R_1 + R_2} = \frac{24\,\text{V}}{8.8\,\Omega + 4.4\,\Omega} = 1.818\,\text{A}$$

The voltage at point a is the voltage across the $4.4\,\Omega$-resistor.

$$V_a = IR_2 = (1.818\,\text{A})(4.4\,\Omega) = \boxed{8.0\,\text{V}}$$

(*b*) With the switch open, the capacitors are in series with each other. Find the equivalent capacitance. The charge stored on the equivalent capacitance is the same value as the charge stored on each capacitor in series.

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} \;\rightarrow\; C_{\text{eq}} = \frac{C_1 C_2}{C_1 + C_2} = \frac{(0.48\,\mu\text{F})(0.36\,\mu\text{F})}{(0.48\,\mu\text{F} + 0.36\,\mu\text{F})} = 0.2057\,\mu\text{F}$$

$$Q_{\text{eq}} = VC_{\text{eq}} = (24.0\,\text{V})(0.2057\,\mu\text{F}) = 4.937\,\mu\text{C} = Q_1 = Q_2$$

The voltage at point b is the voltage across the $0.24\,\mu\text{F}$-capacitor.

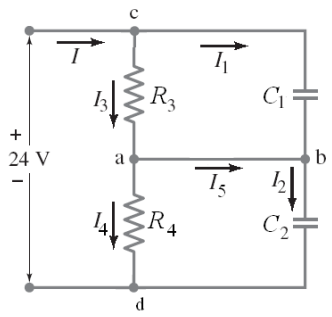
$$V_b = \frac{Q_2}{C_2} = \frac{4.937\,\mu\text{C}}{0.36\,\mu\text{F}} = 13.7\,\text{V} \approx \boxed{14\,\text{V}}$$

(*c*) The switch is now closed. After equilibrium has been reached a long time, there is no current flowing in the capacitors, and so the resistors are again in series, and the voltage of point a must be 8.0 V. Point b is connected by a conductor to point a, and so point b must be at the same potential as point a, $\boxed{8.0\,\text{V}}$. This also means that the voltage across C_2 is 8.0 V, and the voltage across C_1 is 16 V.

(*d*) Find the charge on each of the capacitors, which are no longer in series.

$$Q_1 = V_1 C_1 = (16\,\text{V})(0.48\,\mu\text{F}) = 7.68\,\mu\text{C}$$

$$Q_2 = V_2 C_2 = (8.0\,\text{V})(0.36\,\mu\text{F}) = 2.88\,\mu\text{C}$$



When the switch was open, point b had a net charge of 0, because the charge on the negative plate of C_1 had the same magnitude as the charge on the positive plate of C_2. With the switch closed, these charges are not equal. The net charge at point b is the sum of the charge on the negative plate of C_1 and the charge on the positive plate of C_2.

$$Q_b = -Q_1 + Q_2 = -7.68\,\mu\text{C} + 2.88\,\mu\text{C} = -4.80\,\mu\text{C} \approx -4.8\,\mu\text{C}$$

Thus $\boxed{4.8\,\mu\text{C}}$ of charge has passed through the switch, from right to left.

52. Because there are no simple series or parallel connections in this circuit, we use Kirchhoff's rules to write equations for the currents, as labeled in our diagram. We write junction equations for the junctions c and d. We then write loop equations for each of the three loops. We set the current through the capacitor equal to the derivative of the charge on the capacitor.

$$I = I_1 + I_3 \ \ [1] \ ; \ I = I_2 + I_4 \ \ [2] \ ; \ \mathscr{E} - \frac{Q_1}{C_1} - \frac{Q_2}{C_2} = 0 \ \ [3]$$

$$\frac{Q_1}{C_1} - I_3 R_3 = 0 \ \ [4] \ ; \ \ \frac{Q_2}{C_2} - I_4 R_4 = 0 \ \ [5]$$

We differentiate Eq. [3] with respect to time and set the derivative of the charge equal to the current.

$$0 = \frac{d\mathscr{E}}{dt} - \frac{dQ_1}{dt}\frac{1}{C_1} - \frac{dQ_2}{dt}\frac{1}{C_2} = 0 - \frac{I_1}{C_1} - \frac{I_2}{C_2} \rightarrow I_2 = -I_1\frac{C_2}{C_1}$$

We then substitute Eq. [1] into Eq. [2] to eliminate I. Then using Eqs. [4] and [5] we eliminate I_3 and I_4 from the resulting equation. We eliminate I_2 using the derivative equation above.

$$I_1 + I_3 = I_2 + I_4 \ \ ; \ I_1 + \frac{Q_1}{R_3 C_1} = -I_1\frac{C_2}{C_1} \ + \frac{Q_2}{R_4 C_2}$$

Finally, we eliminate Q_2 using Eq.[3].

$$I_1 + \frac{Q_1}{R_3 C_1} = -I_1\frac{C_2}{C_1} \ + \frac{1}{R_4}\left(\mathscr{E} - \frac{Q_1}{C_1}\right) \ \rightarrow \ \mathscr{E} = I_1 R_4\left(\frac{C_1 + C_2}{C_1}\right) + Q_1\left(\frac{R_4 + R_3}{R_3 C_1}\right) \ \rightarrow$$

$$\mathscr{E} = I_1 R + \frac{Q_1}{C} \qquad \text{where} \quad R = R_4\left(\frac{C_1 + C_2}{C_1}\right) \text{ and } C = C_1\left(\frac{R_3}{R_4 + R_3}\right)$$

This final equation represents a simple RC circuit, with time constant $\tau = RC$.

$$\tau = RC = R_4\left(\frac{C_1 + C_2}{C_1}\right)C_1\left(\frac{R_3}{R_4 + R_3}\right) = \frac{R_4 R_3 (C_1 + C_2)}{R_4 + R_3}$$

$$= \frac{(8.8\,\Omega)(4.4\,\Omega)(0.48\,\mu\text{F} + 0.36\,\mu\text{F})}{8.8\,\Omega + 4.4\,\Omega} = \boxed{2.5\,\mu\text{s}}$$

53. The full-scale current is the reciprocal of the sensitivity.

$$I_{\substack{\text{full-}\\\text{scale}}} = \frac{1}{35{,}000\,\Omega/\text{V}} = \boxed{2.9\times10^{-5}\,\text{A}} \text{ or } 29\,\mu\text{A}$$

54. The resistance is the full-scale voltage multiplied by the sensitivity.

$$R = V_{\substack{\text{full-}\\\text{scale}}}\,(\text{sensitivity}) = (250\,\text{V})(35{,}000\,\Omega/\text{V}) = 8.75\times10^6\,\Omega \approx \boxed{8.8\times10^6\,\Omega}$$

55. (*a*) The current for full-scale deflection of the galvanometer is

$$I_\text{G} = \frac{1}{\text{sensitivity}} = \frac{1}{45{,}000\,\Omega/\text{V}} = 2.222\times10^{-5}\,\text{A}$$

To make an ammeter, a shunt resistor must be placed in parallel with the galvanometer. The voltage across the shunt resistor must be the voltage across the galvanometer. The total current is to be 2.0 A. See Figure 26-28 for a circuit diagram.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_G r_G = I_s R_s \quad \rightarrow \quad R_s = \frac{I_G}{I_s} r_G = \frac{I_G}{I_{full} - I_G} r_G = \frac{2.222 \times 10^{-5}\,\text{A}}{2.0\,\text{A} - 2.222 \times 10^{-5}\,\text{A}} (20.0\,\Omega)$$

$$= 2.222 \times 10^{-4}\,\Omega \approx \boxed{2.2 \times 10^{-4}\,\Omega \text{ in parallel}}$$

(*b*) To make a voltmeter, a resistor must be placed in series with the galvanometer, so that the desired full scale voltage corresponds to the full scale current of the galvanometer. See Figure 26-29 for a circuit diagram. The total current must be the full-scale deflection current.

$$V_{full} = I_G (r_G + R) \quad \rightarrow$$

$$R = \frac{V_{full}}{I_G} - r_G = \frac{1.00\,\text{V}}{2.222 \times 10^{-5}\,\text{A}} - 20.0\,\Omega = 44985\,\Omega \approx \boxed{45\,\text{k}\Omega \text{ in series}}$$

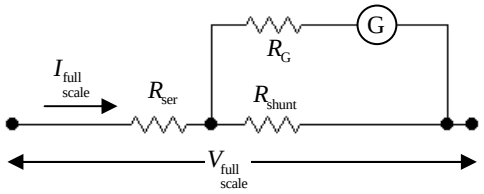
56. (*a*) To make an ammeter, a shunt resistor must be placed in parallel with the galvanometer. The voltage across the shunt resistor must be the voltage across the galvanometer. See Figure 26-28 for a circuit diagram.

$$V_{shunt} = V_G \quad \rightarrow \quad (I_{full} - I_G) R_{shunt} = I_G R_G \quad \rightarrow$$

$$R_{shunt} = \frac{I_G R_G}{(I_{full} - I_G)} = \frac{(55 \times 10^{-6}\,\text{A})(32\,\Omega)}{(25\,\text{A} - 55 \times 10^{-6}\,\text{A})} = \boxed{7.0 \times 10^{-5}\,\Omega}$$

(*b*) To make a voltmeter, a resistor must be placed in series with the galvanometer, so that the desired full-scale voltage corresponds to the full scale current of the galvanometer. See Figure 26-29 for a circuit diagram.

$$V_{full\ scale} = I_G (R_{ser} + R_G) \quad \rightarrow \quad R_{ser} = \frac{V_{full\ scale}}{I_G} - R_G = \frac{250\,\text{V}}{55 \times 10^{-6}\,\text{A}} - 30\,\Omega = \boxed{4.5 \times 10^6\,\Omega}$$



57. We divide the full-scale voltage of the electronic module by the module's internal resistance to determine the current through the module that will give full-scale deflection. Since the module and R_2 are in parallel they will have the same voltage drop across them (400 mV) and their currents will add to equal the current through R_1. We set the voltage drop across R_1 and R_2 equal to the 40 volts and solve the resulting equation for R_2.

$$I_{meter} = \frac{V_{meter}}{r} = \frac{400\text{ mV}}{100\text{ M}\Omega} = 4.00\text{ nA} \;;\; I_2 = \frac{V_{meter}}{R_2} \;;\; I_1 = I_2 + I_{meter} = \frac{V_{meter}}{R_2} + I_{meter}$$

$$V = I_1 R_1 + V_{meter} \quad \rightarrow \quad (V - V_{meter}) = \left(\frac{V_{meter}}{R_2} + I_{meter} \right) R_1 \quad \rightarrow$$

$$R_2 = \frac{R_1 V_{meter}}{(V - V_{meter}) - I_{meter} R_1} = \frac{(10 \times 10^6\ \Omega)(0.400\text{ V})}{(40\text{ V} - 0.400\text{ V}) - (4.00 \times 10^{-9}\text{ A})(10 \times 10^6\ \Omega)} = \boxed{100\text{ k}\Omega}$$

58. To make a voltmeter, a resistor R_{ser} must be placed in series with the existing meter so that the desired full scale voltage corresponds to the full scale current of the galvanometer. We know that 25 mA produces full scale deflection of the galvanometer, so the voltage drop across the total meter must be 25 V when the current through the meter is 25 mA.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$V_{\substack{\text{full}\\\text{scale}}} = I_{\substack{\text{full}\\\text{scale}}} R_{\text{eq}} = I_{\substack{\text{full}\\\text{scale}}} \left[R_{\text{ser}} + \left(\frac{1}{R_{\text{G}}} + \frac{1}{R_{\text{shunt}}} \right)^{-1} \right] \rightarrow$$

$$R_{\text{ser}} = \frac{V_{\substack{\text{full}\\\text{scale}}}}{I_{\substack{\text{full}\\\text{scale}}}} - \left(\frac{1}{R_{\text{G}}} + \frac{1}{R_{\text{shunt}}} \right)^{-1} = \frac{25\,\text{V}}{25\times10^{-3}\,\text{A}} - \left(\frac{1}{33\,\Omega} + \frac{1}{0.20\,\Omega} \right)^{-1} = 999.8\,\Omega \approx \boxed{1000\,\Omega}$$

The sensitivity is $\dfrac{1000\,\Omega}{25\,\text{V}} = \boxed{40\,\Omega/\text{V}}$

59. If the voltmeter were ideal, then the only resistance in the circuit would be the series combination of the two resistors. The current can be found from the battery and the equivalent resistance, and then the voltage across each resistor can be found.

$$R_{\text{tot}} = R_1 + R_2 = 44\,\text{k}\Omega + 27\,\text{k}\Omega = 71\,\text{k}\Omega \;;\; I = \frac{V}{R_{\text{tot}}} = \frac{45\,\text{V}}{71\times10^3\,\Omega} = 6.338\times10^{-4}\,\text{A}$$

$$V_{44} = IR_1 = \left(6.338\times10^{-4}\,\text{A}\right)\left(44\times10^3\,\Omega\right) = 27.89\,\text{V}$$

$$V_{27} = IR_2 = \left(6.338\times10^{-4}\,\text{A}\right)\left(27\times10^3\,\Omega\right) = 17.11\,\text{V}$$

Now put the voltmeter in parallel with the $44\,\text{k}\Omega$ resistor. Find its equivalent resistance, and then follow the same analysis as above.

$$R_{\text{eq}} = \left(\frac{1}{44\,\text{k}\Omega} + \frac{1}{95\,\text{k}\Omega} \right)^{-1} = 30.07\,\text{k}\Omega$$

$$R_{\text{tot}} = R_{\text{eq}} + R_2 = 30.07\,\text{k}\Omega + 27\text{k}\Omega = 57.07\,\text{k}\Omega \qquad I = \frac{V}{R_{\text{tot}}} = \frac{45\,\text{V}}{57.07\times10^3\,\Omega} = 7.885\times10^{-4}\,\text{A}$$

$$V_{44} = V_{\text{eq}} = IR_{\text{eq}} = \left(7.885\times10^{-4}\,\text{A}\right)\left(30.07\times10^3\,\Omega\right) = 23.71\,\text{V} \approx \boxed{24\,\text{V}}$$

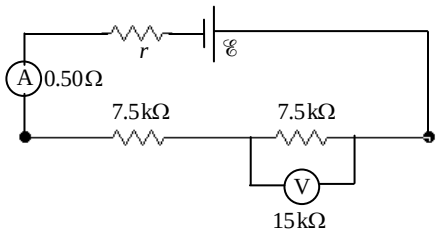
$$\%\text{ error} = \frac{23.71\,\text{V} - 27.89\,\text{V}}{27.89\,\text{V}} \times 100 = \boxed{-15\%\,(\text{reading too low})}$$

And now put the voltmeter in parallel with the $27\,\text{k}\Omega$ resistor, and repeat the process.

$$R_{\text{eq}} = \left(\frac{1}{27\,\text{k}\Omega} + \frac{1}{95\,\text{k}\Omega} \right)^{-1} = 21.02\,\text{k}\Omega$$

$$R_{\text{tot}} = R_{\text{eq}} + R_1 = 21.02\,\text{k}\Omega + 44\,\text{k}\Omega = 65.02\,\text{k}\Omega \qquad I = \frac{V}{R_{\text{tot}}} = \frac{45\,\text{V}}{65.02\times10^3\,\Omega} = 6.921\times10^{-4}\,\text{A}$$

$$V_{27} = V_{\text{eq}} = IR_{\text{eq}} = \left(6.921\times10^{-4}\,\text{A}\right)\left(21.02\times10^3\,\Omega\right) = 14.55\text{V} \approx \boxed{15\,\text{V}}$$



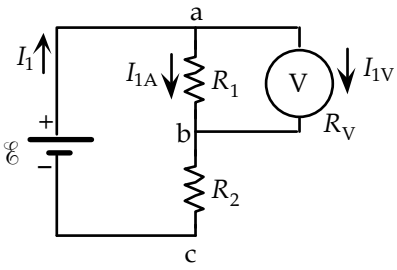
$$\%\text{ error} = \frac{14.55\,\text{V} - 17.11\text{V}}{17.11\,\text{V}} \times 100 = \boxed{-15\%\ (\text{reading too low})}$$

60. The total resistance with the ammeter present is $R_{\text{eq}} = 650\,\Omega + 480\,\Omega + 53\,\Omega = 1183\,\Omega$. The voltage supplied by the battery is found from Ohm's law to be $V_{\text{battery}} = IR_{\text{eq}} = \left(5.25\times10^{-3}\,\text{A}\right)\left(1183\,\Omega\right)$ $= 6.211\,\text{V}$. When the ammeter is removed, we assume that the battery voltage does not change. The equivalent resistance changes to $R'_{\text{eq}} = 1130\,\Omega$, and the new current is again found from Ohm's law.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I = \frac{V_{\text{battery}}}{R'_{\text{eq}}} = \frac{6.211\,\text{V}}{1130\,\Omega} = \boxed{5.50\times10^{-3}\,\text{A}}$$

61. Find the equivalent resistance for the entire circuit, and then find the current drawn from the source. That current will be the ammeter reading. The ammeter and voltmeter symbols in the diagram below are each assumed to have resistance.



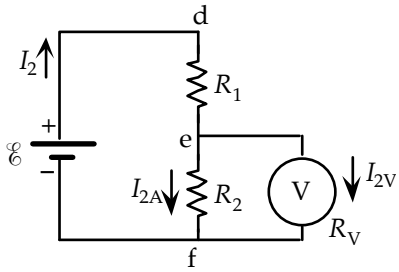
$$R_{\text{eq}} = 1.0\,\Omega + 0.50\,\Omega + 7500\,\Omega + \frac{(7500\,\Omega)(15000\,\Omega)}{(7500\,\Omega + 15000\,\Omega)}$$

$$= 12501.5\,\Omega \approx 12500\,\Omega \;;\; I_{\text{source}} = \frac{\mathscr{E}}{R_{\text{eq}}} = \frac{12.0\,\text{V}}{12500\,\Omega} = \boxed{9.60\times10^{-4}\,\text{A}}$$

The voltmeter reading will be the source current times the equivalent resistance of the resistor–voltmeter combination.

$$V_{\text{meter}} = I_{\text{source}}R_{\text{eq}} = \left(9.60\times10^{-4}\,\text{A}\right)\frac{(7500\,\Omega)(15000\,\Omega)}{(7500\,\Omega + 15000\,\Omega)} = \boxed{4.8\,\text{V}}$$

62. From the first diagram, write the sum of the currents at junction a, and then substitute in for those currents as shown.



$$I_1 = I_{1A} + I_{1V}$$

$$\mathscr{E} - V_{R_1} - I_1R_2 = 0 \;\rightarrow\; I_1 = \frac{\mathscr{E} - V_{R_1}}{R_2} \;;\; I_{1A} = \frac{V_{R_1}}{R_1} \;;\; I_{1V} = \frac{V_{1V}}{R_V}$$

$$\frac{\mathscr{E} - V_{R_1}}{R_2} = \frac{V_{R_1}}{R_1} + \frac{V_{1V}}{R_V}$$

Then do a similar procedure for the second diagram.

$$I_2 = I_{2A} + I_{2V}$$

$$\mathscr{E} - I_2R_1 - V_{R_2} = 0 \;\rightarrow\; I_2 = \frac{\mathscr{E} - V_{R_2}}{R_1} \;;\; I_{2A} = \frac{V_{R_2}}{R_2} \;;\; I_{2V} = \frac{V_{2V}}{R_V}$$

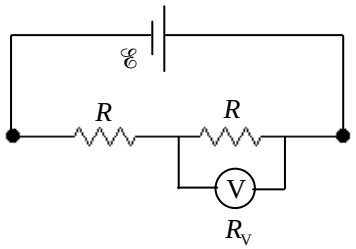
$$\frac{\mathscr{E} - V_{R_2}}{R_1} = \frac{V_{R_2}}{R_2} + \frac{V_{2V}}{R_V}$$

Now there are two equations in the two unknowns of R_1 and R_2. Solve for the reciprocal values and then find the resistances. Assume that all resistances are measured in kilohms.

$$\frac{\mathscr{E} - V_{R_1}}{R_2} = \frac{V_{R_1}}{R_1} + \frac{V_{1V}}{R_V} \;\rightarrow\; \frac{12.0 - 5.5}{R_2} = \frac{5.5}{R_1} + \frac{5.5}{18.0} \;\rightarrow\; \frac{6.5}{R_2} = \frac{5.5}{R_1} + 0.30556$$

$$\frac{\mathscr{E} - V_{R_2}}{R_1} = \frac{V_{R_2}}{R_2} + \frac{V_{2V}}{R_V} \;\rightarrow\; \frac{12.0 - 4.0}{R_1} = \frac{4.0}{R_2} + \frac{4.0}{18.0} \;\rightarrow\; \frac{8.0}{R_1} = \frac{4.0}{R_2} + 0.22222$$

$$\frac{8.0}{R_1} = \frac{4.0}{R_2} + 0.22222 \;\rightarrow\; \frac{1}{R_2} = \frac{2}{R_1} - 0.05556$$



$$\frac{6.5}{R_2} = \frac{5.5}{R_1} + 0.30556 \;\rightarrow\; 6.5\left(\frac{2}{R_1} - 0.05556\right) = \frac{5.5}{R_1} + 0.30556 \;\rightarrow\; \frac{1}{R_1} = \frac{0.66667}{7.5} \;\rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$R_1 = 11.25\,\text{k}\Omega \;;\; \frac{1}{R_2} = \frac{2}{R_1} - 0.05556 \;\rightarrow\; R_2 = 8.18\,\text{k}\Omega$$

So the final results are $\boxed{R_1 = 11\,\text{k}\Omega \;;\; R_2 = 8.2\,\text{k}\Omega}$

63. The sensitivity of the voltmeter is 1000 ohms per volt on the 3.0 volt scale, so it has a resistance of 3000 ohms. The circuit is shown in the diagram. Find the equivalent resistance of the meter–resistor parallel combination and the entire circuit.

$$R_p = \left(\frac{1}{R} + \frac{1}{R_V}\right)^{-1} = \frac{R_V R}{R_V + R} = \frac{(3000\,\Omega)(9400\,\Omega)}{3000\,\Omega + 9400\,\Omega} = 2274\,\Omega$$

$$R_{eq} = R + R_p = 2274\,\Omega + 9400\,\Omega = 11674\,\Omega$$

Using the meter reading of 2.3 volts, calculate the current into the parallel combination, which is the current delivered by the battery. Use that current to find the EMF of the battery.

$$I = \frac{V}{R_p} = \frac{2.3\,\text{V}}{2274\,\Omega} = 1.011\times10^{-3}\,\text{A}$$

$$\mathscr{E} = IR_{eq} = \left(1.011\times10^{-3}\,\text{A}\right)(11674\,\Omega) = 11.80\,\text{V} \approx \boxed{12\,\text{V}}$$

64. By calling the voltmeter "high resistance," we can assume it has no current passing through it. Write Kirchhoff's loop rule for the circuit for both cases, starting with the negative pole of the battery and proceeding counterclockwise.

Case 1: $V_{meter} = V_1 = I_1 R_1 \quad \mathscr{E} - I_1 r - I_1 R_1 = 0 \;\rightarrow\; \mathscr{E} = I_1(r + R_1) = \frac{V_1}{R_1}(r + R_1)$

Case 2: $V_{meter} = V_2 = I_2 R_2 \quad \mathscr{E} - I_2 r - I_2 R_2 = 0 \;\rightarrow\; \mathscr{E} = I_2(r + R_2) = \frac{V_2}{R_2}(r + R_2)$

Solve these two equations for the two unknowns of $\mathscr{E}$ and r.

$$\mathscr{E} = \frac{V_1}{R_1}(r + R_1) = \frac{V_2}{R_2}(r + R_2) \;\rightarrow$$

$$r = R_1 R_2\left(\frac{V_2 - V_1}{V_1 R_2 - V_2 R_1}\right) = (35\Omega)(14.0\Omega)\left(\frac{8.1\,\text{V} - 9.7\,\text{V}}{(9.7\,\text{V})(14.0\Omega) - (8.1\,\text{V})(35\Omega)}\right) = 5.308\,\Omega \approx \boxed{5.3\Omega}$$

$$\mathscr{E} = \frac{V_1}{R_1}(r + R_1) = \frac{9.7\,\text{V}}{35\Omega}(5.308\,\Omega + 35\Omega) = 11.17\,\text{V} \approx \boxed{11\,\text{V}}$$

65. We connect the battery in series with the body and a resistor. The current through this series circuit is the voltage supplied by the battery divided by the sum of the resistances. The voltage drop across the body is equal to the current multiplied by the body's resistance. We set the voltage drop across the body equal to 0.25 V and solve for the necessary resistance.

$$I = \frac{\mathscr{E}}{R + R_B}$$

$$V = IR_B = \frac{\mathscr{E}\,R_B}{R + R_B} \rightarrow R = \left(\frac{\mathscr{E}}{V} - 1\right)R_B = \left(\frac{1.5\,\text{V}}{0.25\,\text{V}} - 1\right)(1800\,\Omega) = 9000\,\Omega = \boxed{9.0\,\text{k}\Omega}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

66. (*a*) Since $P = V^2/R$ and the voltage is the same for each combination, the power and resistance are inversely related to each other. So for the 50 W output, use the higher-resistance filament. For the 100 W output, use the lower-resistance filament. For the 150 W output, use the filaments in parallel.

(*b*) $P = V^2/R \rightarrow$

$$R = \frac{V^2}{P} \qquad R_{50\,\mathrm{W}} = \frac{(120\,\mathrm{V})^2}{50\,\mathrm{W}} = 288\,\Omega \approx \boxed{290\,\Omega} \qquad R_{100\,\mathrm{W}} = \frac{(120\,\mathrm{V})^2}{100\,\mathrm{W}} = 144\,\Omega \approx \boxed{140\,\Omega}$$

As a check, the parallel combination of the resistors gives the following.

$$R_\mathrm{p} = \frac{R_1 R_2}{R_1 + R_2} = \frac{(288\,\Omega)(144\,\Omega)}{288\,\Omega + 144\,\Omega} = 96\,\Omega \qquad P = \frac{V^2}{R} = \frac{(120\,\mathrm{V})^2}{96\,\Omega} = 150\,\mathrm{W}.$$

67. The voltage drop across the two wires is the 3.0 A current times their total resistance.

$$V_\mathrm{wires} = IR_\mathrm{wires} = (3.0\,\mathrm{A})(0.0065\,\Omega/\mathrm{m})(130\,\mathrm{m})R_\mathrm{p} = 2.535\,\mathrm{V} \approx \boxed{2.5\,\mathrm{V}}$$

Thus the voltage applied to the apparatus is $V = V_\mathrm{source} - V_\mathrm{wires} = 120\,\mathrm{V} - 2.535\,\mathrm{V} = 117.465\,\mathrm{V} \approx \boxed{117\,\mathrm{V}}$.

68. The charge on the capacitor and the current in the resistor both decrease exponentially, with a time constant of $\tau = RC$. The energy stored in the capacitor is given by $U = \frac{1}{2}\frac{Q^2}{C}$, and the power dissipated in the resistor is given by $P = I^2R$.

$$Q = Q_0 e^{-t/RC} \;;\; I = I_0 e^{-t/RC} = \frac{V_0}{R} e^{-t/RC} = \frac{Q_0}{RC} e^{-t/RC}$$

$$U_\mathrm{decrease} = -\Delta U = U_{t=0} - U_{t=\tau} = \tfrac{1}{2}\left(\frac{Q^2}{C}\right)_{t=0} - \tfrac{1}{2}\left(\frac{Q^2}{C}\right)_{t=\tau} = \tfrac{1}{2}\frac{Q_0^2}{C} - \tfrac{1}{2}\left(\frac{Q_0 e^{-1}}{C}\right)^2 = \tfrac{1}{2}\frac{Q_0^2}{C}\left(1 - e^{-2}\right)$$

$$U_\mathrm{dissipated} = \int P\,dt = \int_0^\tau I^2 R\,dt = \int_0^\tau \left(\frac{Q_0}{RC} e^{-t/RC}\right)^2 R\,dt = \frac{Q_0^2}{RC^2}\int_0^\tau e^{-2t/RC}\,dt = \frac{Q_0^2}{RC^2}\left(-\frac{RC}{2}\right)\left(e^{-2t/RC}\right)_0^\tau$$

$$= -\tfrac{1}{2}\frac{Q_0^2}{C}\left(e^{-2} - 1\right) = \tfrac{1}{2}\frac{Q_0^2}{C}\left(1 - e^{-2}\right)$$

And so we see that $\boxed{U_\mathrm{decrease} = U_\mathrm{dissipated}}$.

69. The capacitor will charge up to 75% of its maximum value, and then discharge. The charging time is the time for one heartbeat.

$$t_\mathrm{beat} = \frac{1\,\mathrm{min}}{72\,\mathrm{beats}} \times \frac{60\,\mathrm{s}}{1\,\mathrm{min}} = 0.8333\,\mathrm{s}$$

$$V = V_0\left(1 - e^{-\frac{t}{RC}}\right) \;\rightarrow\; 0.75V_0 = V_0\left(1 - e^{-\frac{t_\mathrm{beat}}{RC}}\right) \;\rightarrow\; e^{-\frac{t_\mathrm{beat}}{RC}} = 0.25 \;\rightarrow\; \left(-\frac{t_\mathrm{beat}}{RC}\right) = \ln(0.25) \;\rightarrow$$

$$R = -\frac{t_\mathrm{beat}}{C\ln(0.25)} = -\frac{0.8333\,\mathrm{s}}{(6.5\times10^{-6}\,\mathrm{F})(-1.3863)} = \boxed{9.2\times10^4\,\Omega}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

70. (*a*) Apply Ohm's law to find the current.

$$I = \frac{V_{\text{body}}}{R_{\text{body}}} = \frac{110\,\text{V}}{950\,\Omega} = 0.116\,\text{A} \approx \boxed{0.12\,\text{A}}$$

(*b*) The description of "alternative path to ground" is a statement that the $35\,\Omega$ path is in parallel with the body. Thus the full 110 V is still applied across the body, and so the current is the same: $\boxed{0.12\,\text{A}}$.

(*c*) If the current is limited to a total of 1.5 A, then that current will get divided between the person and the parallel path. The voltage across the body and the parallel path will be the same, since they are in parallel.

$$V_{\text{body}} = V_{\text{alternate}} \quad \rightarrow \quad I_{\text{body}} R_{\text{body}} = I_{\text{alternate}} R_{\text{alternate}} = \left(I_{\text{total}} - I_{\text{body}}\right) R_{\text{alternate}} \quad \rightarrow$$

$$I_{\text{body}} = I_{\text{total}} \frac{R_{\text{alternate}}}{\left(R_{\text{body}} + R_{\text{alternate}}\right)} = \left(1.5\,\text{A}\right) \frac{35\,\Omega}{950\,\Omega + 35\,\Omega} = 0.0533\,\text{A} \approx \boxed{53\,\text{mA}}$$

This is still a very dangerous current.

71. (*a*) If the ammeter shows no current with the closing of the switch, then points B and D must be at the same potential, because the ammeter has some small resistance. Any potential difference between points B and D would cause current to flow through the ammeter. Thus the potential drop from A to B must be the same as the drop from A to D. Since points B and D are at the same potential, the potential drop from B to C must be the same as the drop from D to C. Use these two potential relationships to find the unknown resistance.

$$V_{\text{BA}} = V_{\text{DA}} \quad \rightarrow \quad I_3 R_3 = I_1 R_1 \quad \rightarrow \quad \frac{R_3}{R_1} = \frac{I_1}{I_3}$$

$$V_{\text{CB}} = V_{\text{CD}} \quad \rightarrow \quad I_3 R_x = I_1 R_2 \quad \rightarrow \quad R_x = R_2 \frac{I_1}{I_3} = \boxed{R_2 R_3 / R_1}$$

(*b*) $$R_x = R_2 \frac{R_3}{R_1} = \left(972\,\Omega\right)\left(\frac{78.6\,\Omega}{630\,\Omega}\right) = \boxed{121\,\Omega}$$

72. From the solution to problem 71, the unknown resistance is given by $R_x = R_2 R_3 / R_1$. We use that with Eq. 25-3 to find the length of the wire.

$$R_x = R_2 \frac{R_3}{R_1} = \frac{\rho L}{A} = \frac{\rho L}{\pi\left(d/2\right)^2} = \frac{4\rho L}{\pi d^2} \quad \rightarrow$$

$$L = \frac{R_2 R_3 \pi d^2}{4 R_1 \rho} = \frac{\left(29.2\,\Omega\right)\left(3.48\,\Omega\right)\pi\left(1.22\times10^{-3}\,\text{m}\right)^2}{4\left(38.0\,\Omega\right)\left(10.6\times10^{-8}\,\Omega\cdot\text{m}\right)} = \boxed{29.5\,\text{m}}$$

73. Divide the power by the required voltage to determine the current drawn by the hearing aid.

$$I = \frac{P}{V} = \frac{2.5\text{ W}}{4.0\text{ V}} = 0.625\text{ A}$$

Use Eq. 26-1 to calculate the terminal voltage across the three batteries for mercury and dry cells.

$$V_{\text{Hg}} = 3\left(\mathscr{E} - Ir\right) = 3\left[1.35\text{ V} - \left(0.625\text{ A}\right)\left(0.030\ \Omega\right)\right] = 3.99\text{ V}$$

$$V_{\text{D}} = 3\left(\mathscr{E} - Ir\right) = 3\left[1.50\text{ V} - \left(0.625\text{ A}\right)\left(0.35\ \Omega\right)\right] = 3.84\text{ V}$$

The terminal voltage of the mercury cell batteries is closer to the required 4.0 V than the voltage from the dry cell.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

74. One way is to connect *N* resistors in series. If each resistor can dissipate 0.5 W, then it will take 7 resistors in series to dissipate 3.5 W. Since the resistors are in series, each resistor will be 1/7 of the total resistance.

$$R = \frac{R_{eq}}{7} = \frac{3200\,\Omega}{7} = 457\,\Omega \approx 460\,\Omega$$

So connect $\boxed{\text{7 resistors of } 460\,\Omega \text{ each, rated at ½ W, in series}}$.

Or, the resistors could be connected in parallel. Again, if each resistor watt can dissipate 0.5 W, then it will take 7 resistors in parallel to dissipate 3.5 W. Since the resistors are in parallel, the equivalent resistance will be 1/7 of each individual resistance.

$$\frac{1}{R_{eq}} = 7\left(\frac{1}{R}\right) \quad \rightarrow \quad R = 7R_{eq} = 7\left(3200\,\Omega\right) = 22.4\,\text{k}\Omega$$

So connect $\boxed{\text{7 resistors of } 22.4\,\text{k}\Omega \text{ each, rated at ½ W, in parallel}}$.

75. To build up a high voltage, the cells will have to be put in series. 120 V is needed from a series of 0.80 V cells. Thus $\dfrac{120\,\text{V}}{0.80\,\text{V/cell}} = 150$ cells are needed to provide the desired voltage. Since these cells are all in series, their current will all be the same at 350 mA. To achieve the higher current desired, banks made of 150 cells each can be connected in parallel. Then their voltage will still be at 120 V, but the currents would add making a total of $\dfrac{1.3\,\text{A}}{350\times10^{-3}\,\text{A/bank}} = 3.71\text{ banks} \approx 4\text{ banks}$. So the total number of cells is $\boxed{\text{600 cells}}$. The panel area is $600\text{ cells}\left(9.0\times10^{-4}\,\text{m}^2\text{/cell}\right) = \boxed{0.54\,\text{m}^2}$.

The cells should be wired in $\boxed{\text{4 banks of 150 cells in series per bank, with the banks in parallel}}$. This will produce 1.4 A at 120 V. To optimize the output, $\boxed{\text{always have the panel pointed directly at the sun}}$.

76. (*a*) If the terminal voltage is to be 3.0 V, then the voltage across R_1 will be 9.0 V. This can be used to find the current, which then can be used to find the value of R_2.

$$V_1 = IR_1 \quad \rightarrow \quad I = \frac{V_1}{R_1} \qquad V_2 = IR_2 \quad \rightarrow$$

$$R_2 = \frac{V_2}{I} = R_1\frac{V_2}{V_1} = \left(14.5\,\Omega\right)\frac{3.0\,\text{V}}{9.0\,\text{V}} = 4.833\,\Omega \approx \boxed{4.8\,\Omega}$$

(*b*) If the load has a resistance of $7.0\,\Omega$, then the parallel combination of R_2 and the load must be used to analyze the circuit. The equivalent resistance of the circuit can be found and used to calculate the current in the circuit. Then the terminal voltage can be found from Ohm's law, using the parallel combination resistance.

$$R_{2+\text{load}} = \frac{R_2R_{\text{load}}}{R_2 + R_{\text{load}}} = \frac{\left(4.833\,\Omega\right)\left(7.0\,\Omega\right)}{11.833\,\Omega} = 2.859\,\Omega \qquad R_{eq} = 2.859\,\Omega + 14.5\,\Omega = 17.359\,\Omega$$

$$I = \frac{V}{R_{eq}} = \frac{12.0\,\text{V}}{17.359\,\Omega} = 0.6913\,\text{A} \qquad V_{\text{T}} = IR_{2+\text{load}} = \left(0.6913\,\text{A}\right)\left(2.859\,\Omega\right) = 1.976\,\text{V} \approx \boxed{2.0\,\text{V}}$$

The presence of the load has affected the terminal voltage significantly.

77. There are two answers because it is not known which direction the given current is flowing through the $4.0\,\text{k}\Omega$ resistor. Assume the current is to the right. The voltage across the $4.0\,\text{k}\Omega$ resistor is given by Ohm's law as $V = IR = \left(3.10\times10^{-3}\,\text{A}\right)\left(4000\,\Omega\right) = 12.4\,\text{V}$. The voltage drop across the $8.0\,\text{k}\Omega$ must be the same, and the current through it is $I = \dfrac{V}{R} = \dfrac{12.4\,\text{V}}{8000\,\Omega} = 1.55\times10^{-3}\,\text{A}$. The total current in the circuit is the sum of the two currents, and so $I_{\text{tot}} = 4.65\times10^{-3}\,\text{A}$. That current can be used to find the terminal voltage of the battery. Write a loop equation, starting at the negative terminal of the unknown battery and going clockwise.

$$V_{\text{ab}} - \left(5000\,\Omega\right)I_{\text{tot}} - 12.4\,\text{V} - 12.0\,\text{V} - \left(1.0\,\Omega\right)I_{\text{tot}} \;\rightarrow$$

$$V_{\text{ab}} = 24.4\text{V} + \left(5001\Omega\right)\left(4.65\times10^{-3}\,\text{A}\right) = 47.65\,\text{V} \approx \boxed{48\,\text{V}}$$

If the current is to the left, then the voltage drop across the parallel combination of resistors is still 12.4 V, but with the opposite orientation. Again write a loop equation, starting at the negative terminal of the unknown battery and going clockwise. The current is now to the left.

$$V_{\text{ab}} + \left(5000\,\Omega\right)I_{\text{tot}} + 12.4\,\text{V} - 12.0\,\text{V} + \left(1.0\,\Omega\right)I_{\text{tot}} \;\rightarrow$$

$$V_{\text{ab}} = -0.4\text{V} - \left(5001\Omega\right)\left(4.65\times10^{-3}\,\text{A}\right) = -23.65\,\text{V} \approx \boxed{-24\,\text{V}}$$

78. The terminal voltage and current are given for two situations. Apply Eq. 26-1 to both of these situations, and solve the resulting two equations for the two unknowns.

$$V_1 = \mathscr{E} - I_1 r \;;\; V_2 = \mathscr{E} - I_2 r \;\rightarrow\; \mathscr{E} = V_1 + I_1 r = V_2 + I_2 r \;\rightarrow$$

$$r = \frac{V_2 - V_1}{I_1 - I_2} = \frac{47.3\,\text{V} - 40.8\,\text{V}}{7.40\,\text{A} - 2.80\,\text{A}} = 1.413\Omega \approx \boxed{1.4\,\Omega}$$

$$\mathscr{E} = V_1 + I_1 r = 40.8\,\text{V} + \left(7.40\,\text{A}\right)\left(1.413\Omega\right) = \boxed{51.3\,\text{V}}$$

79. The current in the circuit can be found from the resistance and the power dissipated. Then the product of that current and the equivalent resistance is equal to the battery voltage.

$$P = I^2 R \;\rightarrow\; I = \sqrt{\frac{P_{33}}{R_{33}}} = \sqrt{\frac{0.80\,\text{W}}{33\Omega}} = 0.1557\,\text{A}$$

$$R_{\text{eq}} = 33\Omega + \left(\frac{1}{68\,\Omega} + \frac{1}{75\,\Omega}\right)^{-1} = 68.66\,\Omega \qquad V = IR_{\text{eq}} = \left(0.1557\,\text{A}\right)\left(68.66\,\Omega\right) = 10.69\,\text{V} \approx \boxed{11\,\text{V}}$$

80. If the switches are both open, then the circuit is a simple series circuit. Use Kirchhoff's loop rule to find the current in that case.

$$6.0\,\text{V} - I\left(50\,\Omega + 20\,\Omega + 10\,\Omega\right) = 0 \;\rightarrow\; I = 6.0\,\text{V}/80\,\Omega = 0.075\,\text{A}$$

If the switches are both closed, the 20-Ω resistor is in parallel with *R*. Apply Kirchhoff's loop rule to the outer loop of the circuit, with the 20-Ω resistor having the current found previously.

$$6.0\,\text{V} - I\left(50\,\Omega\right) - \left(0.075\,\text{A}\right)\left(20\,\Omega\right) = 0 \;\rightarrow\; I = \frac{6.0\,\text{V} - \left(0.075\,\text{A}\right)\left(20\,\Omega\right)}{50\,\Omega} = 0.090\,\text{A}$$

This is the current in the parallel combination. Since 0.075 A is in the 20-Ω resistor, 0.015 A must be in *R*. The voltage drops across *R* and the 20-Ω resistor are the same since they are in parallel.

$$V_{20} = V_R \;\rightarrow\; I_{20}R_{20} = I_R R \;\rightarrow\; R = R_{20}\frac{I_{20}}{I_R} = \left(20\,\Omega\right)\frac{0.075\,\text{A}}{0.015\,\text{A}} = \boxed{100\,\Omega}$$

81. (*a*) We assume that the ammeter is ideal and so has 0 resistance, but that the voltmeter has resistance R_V. Then apply Ohm's law, using the equivalent resistance. We also assume the voltmeter is accurate, and so it is reading the voltage across the battery.

$$V = IR_{eq} = I\frac{1}{\frac{1}{R}+\frac{1}{R_V}} \quad \rightarrow \quad V\left(\frac{1}{R}+\frac{1}{R_V}\right) = I \quad \rightarrow \quad \frac{1}{R}+\frac{1}{R_V} = \frac{I}{V} \quad \rightarrow \quad \boxed{\frac{1}{R} = \frac{I}{V} - \frac{1}{R_V}}$$

(*b*) We now assume the voltmeter is ideal, and so has an infinite resistance, but that the ammeter has resistance R_A. We also assume that the voltmeter is accurate and so is reading the voltage across the battery.

$$V = IR_{eq} = I\left(R + R_A\right) \quad \rightarrow \quad R + R_A = \frac{V}{I} \quad \rightarrow \quad \boxed{R = \frac{V}{I} - R_A}$$

82. (*a*) The 12-Ω and the 25-Ω resistors are in parallel, with a net resistance $R_{1\text{-}2}$ as follows.

$$R_{1\text{-}2} = \left(\frac{1}{12\,\Omega}+\frac{1}{25\,\Omega}\right)^{-1} = 8.108\,\Omega$$

$R_{1\text{-}2}$ is in series with the 4.5-Ω resistor, for a net resistance $R_{1\text{-}2\text{-}3}$ as follows.

$$R_{1\text{-}2\text{-}3} = 4.5\,\Omega + 8.108\,\Omega = 12.608\,\Omega$$

That net resistance is in parallel with the 18-Ω resistor, for a final equivalent resistance as follows.

$$R_{eq} = \left(\frac{1}{12.608\,\Omega}+\frac{1}{18\,\Omega}\right)^{-1} = 7.415\,\Omega \approx \boxed{7.4\,\Omega}$$

(*b*) Find the current in the 18-Ω resistor by using Kirchhoff's loop rule for the loop containing the battery and the 18-Ω resistor.

$$\mathscr{E} - I_{18}R_{18} = 0 \quad \rightarrow \quad I_{18} = \frac{\mathscr{E}}{R_{18}} = \frac{6.0\,\text{V}}{18\,\Omega} = \boxed{0.33\,\text{A}}$$

(*c*) Find the current in $R_{1\text{-}2}$ and the 4.5-Ω resistor by using Kirchhoff's loop rule for the outer loop containing the battery and the resistors $R_{1\text{-}2}$ and the 4.5-Ω resistor.

$$\mathscr{E} - I_{1\text{-}2}R_{1\text{-}2} - I_{1\text{-}2}R_{4.5} = 0 \quad \rightarrow \quad I_{1\text{-}2} = \frac{\mathscr{E}}{R_{1\text{-}2}+R_{4.5}} = \frac{6.0\,\text{V}}{12.608\,\Omega} = 0.4759\,\text{A}$$

This current divides to go through the 12-Ω and 25-Ω resistors in such a way that the voltage drop across each of them is the same. Use that to find the current in the 12-Ω resistor.

$$I_{1\text{-}2} = I_{12} + I_{25} \quad \rightarrow \quad I_{25} = I_{1\text{-}2} - I_{12}$$

$$V_{R_{12}} = V_{R_{25}} \quad \rightarrow \quad I_{12}R_{12} = I_{25}R_{25} = \left(I_{1\text{-}2} - I_{12}\right)R_{25} \quad \rightarrow$$

$$I_{12} = I_{1\text{-}2}\frac{R_{25}}{\left(R_{12}+R_{25}\right)} = \left(0.4759\,\text{A}\right)\frac{25\,\Omega}{37\,\Omega} = \boxed{0.32\,\text{A}}$$

(*d*) The current in the 4.5-Ω resistor was found above to be $I_{1\text{-}2} = 0.4759\,\text{A}$. Find the power accordingly.

$$P_{4.5} = I_{1\text{-}2}^2 R_{4.5} = \left(0.4759\,\text{A}\right)^2\left(4.5\,\Omega\right) = 1.019\,\text{W} \approx \boxed{1.0\,\text{W}}$$

83. Write Kirchhoff's loop rule for the circuit, and substitute for the current and the bulb resistance based on the bulb ratings.

$$P_{\text{bulb}} = \frac{V_{\text{bulb}}^2}{R_{\text{bulb}}} \;\rightarrow\; R_{\text{bulb}} = \frac{V_{\text{bulb}}^2}{P_{\text{bulb}}} \qquad P_{\text{bulb}} = I_{\text{bulb}} V_{\text{bulb}} \;\rightarrow\; I_{\text{bulb}} = \frac{P_{\text{bulb}}}{V_{\text{bulb}}}$$

$$\mathscr{E} - I_{\text{bulb}} R - I_{\text{bulb}} R_{\text{bulb}} = 0 \;\rightarrow$$

$$R = \frac{\mathscr{E}}{I_{\text{bulb}}} - R_{\text{bulb}} = \frac{\mathscr{E}}{P_{\text{bulb}}/V_{\text{bulb}}} - \frac{V_{\text{bulb}}^2}{P_{\text{bulb}}} = \frac{V_{\text{bulb}}}{P_{\text{bulb}}}\left(\mathscr{E} - V_{\text{bulb}}\right) = \frac{3.0\,\text{V}}{2.0\,\text{W}}\left(9.0\,\text{V} - 3.0\,\text{V}\right) = \boxed{9.0\,\Omega}$$

84. The equivalent resistance of the circuit is the parallel combination of the bulb and the lower portion of the potentiometer, in series with the upper portion of the potentiometer. With the slide at position x, the resistance of the lower portion is xR_{var}, and the resistance of the upper portion is $(1-x)R_{\text{var}}$. From that equivalent resistance, we find the current in the loop, the voltage across the bulb, and then the power expended in the bulb.

$$R_{\text{parallel}} = \left(\frac{1}{R_{\text{lower}}} + \frac{1}{R_{\text{bulb}}}\right)^{-1} = \frac{R_{\text{lower}} R_{\text{bulb}}}{R_{\text{lower}} + R_{\text{bulb}}} = \frac{xR_{\text{var}} R_{\text{bulb}}}{xR_{\text{var}} + R_{\text{bulb}}}$$

$$R_{\text{eq}} = (1-x)R_{\text{var}} + R_{\text{parallel}} \;;\; I_{\text{loop}} = \frac{\mathscr{E}}{R_{\text{eq}}} \;;\; V_{\text{bulb}} = I_{\text{loop}} R_{\text{parallel}} \;;\; P_{\text{bulb}} = \frac{V_{\text{bulb}}^2}{R_{\text{bulb}}}$$

(*a*) Consider the case in which $x = 1.00$. In this case, the full battery potential is across the bulb, and so it is obvious that $V_{\text{bulb}} = 120\,\text{V}$. Thus $P_{\text{bulb}} = \frac{V_{\text{bulb}}^2}{R_{\text{bulb}}} = \frac{(120\,\text{V})^2}{240\,\Omega} = \boxed{60\,\text{W}}$.

(*b*) Consider the case in which $x = 0.65$.

$$R_{\text{parallel}} = \frac{xR_{\text{var}} R_{\text{bulb}}}{xR_{\text{var}} + R_{\text{bulb}}} = \frac{(0.65)(150\,\Omega)(240\,\Omega)}{(0.65)(150\,\Omega) + 240\,\Omega} = 69.33\,\Omega$$

$$R_{\text{eq}} = (1-x)R_{\text{var}} + R_{\text{parallel}} = (0.35)(150\,\Omega) + 69.33\,\Omega = 121.83\,\Omega$$

$$I_{\text{loop}} = \frac{\mathscr{E}}{R_{\text{eq}}} = \frac{120\,\text{V}}{121.83\,\Omega} = 0.9850\,\text{A} \;;\; V_{\text{bulb}} = (0.9850\,\text{A})(69.33\,\Omega) = 68.29\,\text{V}$$

$$P_{\text{bulb}} = \frac{(68.29\,\text{V})^2}{240\,\Omega} = 19.43\,\text{W} \approx \boxed{19\,\text{W}}$$

(*c*) Consider the case in which $x = 0.35$.

$$R_{\text{parallel}} = \frac{xR_{\text{var}} R_{\text{bulb}}}{xR_{\text{var}} + R_{\text{bulb}}} = \frac{(0.35)(150\,\Omega)(240\,\Omega)}{(0.35)(150\,\Omega) + 240\,\Omega} = 43.08\,\Omega$$

$$R_{\text{eq}} = (1-x)R_{\text{var}} + R_{\text{parallel}} = (0.65)(150\,\Omega) + 69.33\,\Omega = 140.58\,\Omega$$

$$I_{\text{loop}} = \frac{\mathscr{E}}{R_{\text{eq}}} = \frac{120\,\text{V}}{140.58\,\Omega} = 0.8536\,\text{A} \;;\; V_{\text{bulb}} = (0.8536\,\text{A})(43.08\,\Omega) = 36.77\,\text{V}$$

$$P_{\text{bulb}} = \frac{(36.77\,\text{V})^2}{240\,\Omega} = 5.63\,\text{W} \approx \boxed{5.6\,\text{W}}$$

85. (*a*) When the galvanometer gives a null reading, no current is passing through the galvanometer or the emf that is being measured. All of the current is flowing through the slide wire resistance. Application of the loop rule to the lower loop gives $\mathscr{E} - IR = 0$, since there is no current through the emf to cause voltage drop across any internal resistance. The amount of current flowing through the slide wire resistor will be the same no matter what emf is used since no current is flowing through the lower loop. Apply this relationship to the two emf's.

$$\mathscr{E}_x - IR_x = 0 \;;\; \mathscr{E}_s - IR_s = 0 \;\rightarrow\; ;\; I = \frac{\mathscr{E}_x}{R_x} = \frac{\mathscr{E}_s}{R_s} \;\rightarrow\; \boxed{\mathscr{E}_x = \left(\frac{R_x}{R_s}\right)\mathscr{E}_s}$$

(*b*) Use the equation derived above. We use the fact that the resistance is proportional to the length of the wire, by Eq. 25-3, $R = \rho\ell/A$.

$$\mathscr{E}_x = \left(\frac{R_x}{R_s}\right)\mathscr{E}_s = \left(\frac{\rho\frac{\ell_x}{A}}{\rho\frac{\ell_s}{A}}\right)\mathscr{E}_s = \left(\frac{\ell_x}{\ell_s}\right)\mathscr{E}_s = \left(\frac{45.8\,\text{cm}}{33.6\,\text{cm}}\right)(1.0182\,\text{V}) = \boxed{1.39\,\text{V}}$$

(*c*) If there is current in the galvanometer, then the voltage between points A and C is uncertainty by the voltage drop across the galvanometer, which is $V_G = I_G R_G = \left(0.012\times10^{-3}\,\text{A}\right)(35\,\Omega)$ $= \boxed{4.2\times10^{-4}\,\text{V}}$. The uncertainty might of course be more than this, due to uncertainties compounding from having to measure distance for both the standard emf and the unknown emf. Measuring the distances also has some uncertainty associated with it.

(*d*) Using this null method means that the (unknown) internal resistance of the unknown emf does not enter into the calculation. No current passes through the unknown emf, and so there is no voltage drop across that internal resistance.

86. (*a*) In normal operation, the capacitor is fully charged by the power supply, and so the capacitor voltage is the same as the power supply voltage, and there will be no current through the resistor. If there is an interruption, the capacitor voltage will decrease exponentially – it will discharge. We want the voltage across the capacitor to be at 75% of the full voltage after 0.20 s. Use Eq. 26-9b for the discharging capacitor.

$$V = V_0 e^{-t/RC} \;;\; 0.75V_0 = V_0 e^{-(0.20\,\text{s})/RC} \;\rightarrow\; 0.75 = e^{-(0.20\,\text{s})/RC} \;\rightarrow$$

$$R = \frac{-(0.20\,\text{s})}{C\ln(0.75)} = \frac{-(0.20\,\text{s})}{\left(8.5\times10^{-6}\,\text{F}\right)\ln(0.75)} = 81790\,\Omega \approx \boxed{82\,\text{k}\Omega}$$

(*b*) When the power supply is functioning normally, there is no voltage across the resistor, so the device should NOT be connected between terminals a and b. If the power supply is not functioning normally, there will be a larger voltage across the capacitor than across the capacitor–resistor combination, since some current might be present. This current would result in a voltage drop across the resistor. To have the highest voltage in case of a power supply failure, the device should be connected between terminals $\boxed{\text{b and c}}$.

87. Note that, based on the significant figures of the resistors, that the 1.0-Ω resistor will not change the equivalent resistance of the circuit as determined by the resistors in the switch bank.

Case 1: n = 0 switch closed. The effective resistance of the circuit is 16.0 kΩ. The current in the circuit is $I = \dfrac{16\,\text{V}}{16.0\,\text{k}\Omega} = 1.0\,\text{mA}$. The voltage across the 1.0-Ω resistor is $V = IR$ $= (1.0\,\text{mA})(1.0\,\Omega) = \boxed{1.0\,\text{mV}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

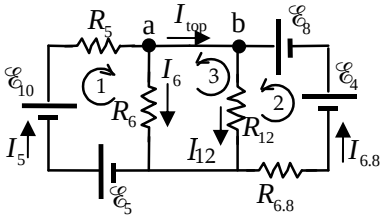
Case 2: $n = 1$ switch closed. The effective resistance of the circuit is $8.0\,\text{k}\Omega$. The current in the circuit is $I = \dfrac{16\,\text{V}}{8.0\,\text{k}\Omega} = 2.0\,\text{mA}$. The voltage across the $1.0\text{-}\Omega$ resistor is $V = IR$

$= (2.0\,\text{mA})(1.0\,\Omega) = \boxed{2.0\,\text{mV}}$.

Case 3: $n = 2$ switch closed. The effective resistance of the circuit is $4.0\,\text{k}\Omega$. The current in the circuit is $I = \dfrac{16\,\text{V}}{4.0\,\text{k}\Omega} = 4.0\,\text{mA}$. The voltage across the $1.0\text{-}\Omega$ resistor is $V = IR$

$= (4.0\,\text{mA})(1.0\,\Omega) = \boxed{4.0\,\text{mV}}$.

Case 4: $n = 3$ and $n = 1$ switches closed. The effective resistance of the circuit is found by the parallel combination of the $2.0\text{-k}\Omega$ and $8.0\text{-k}\Omega$ resistors.



$$R_{\text{eq}} = \left(\frac{1}{2.0\,\text{k}\Omega} + \frac{1}{8.0\,\text{k}\Omega} \right)^{-1} = 1.6\,\text{k}\Omega$$

The current in the circuit is $I = \dfrac{16\,\text{V}}{1.6\,\text{k}\Omega} = 10\,\text{mA}$. The voltage across the $1.0\text{-}\Omega$ resistor is

$V = IR = (10\,\text{mA})(1.0\,\Omega) = \boxed{10\,\text{mV}}$.

So in each case, the voltage across the $1.0\text{-}\Omega$ resistor, if taken in mV, is the expected analog value corresponding to the digital number set by the switches.

88. We have labeled the resistors and the currents through the resistors with the value of the specific resistance, and the emf's with the appropriate voltage value. We apply the junction rule to points a and b, and then apply the loop rule to loops 1, 2, and 3. This enables us to solve for all of the currents.

$I_5 = I_6 + I_{\text{top}}$; $I_{\text{top}} + I_{6.8} = I_{12}$ $\rightarrow$ $I_5 - I_6 = I_{12} - I_{6.8}$ $\rightarrow$

$I_5 + I_{6.8} = I_{12} + I_6$ [1]

$\mathscr{E}_5 + \mathscr{E}_{10} - I_5 R_5 - I_6 R_6 = 0$ [2] (loop 1)

$\mathscr{E}_4 + \mathscr{E}_8 - I_{12} R_{12} - I_{6.8} R_{6.8} = 0$ [3] (loop 2)

$I_{12} R_{12} - I_6 R_6 = 0$ [4] (loop 3)

Use Eq. 4 to substitute $I_6 R_6 = I_{12} R_{12}$ and $I_6 = I_{12} \dfrac{R_{12}}{R_6} = 2I_{12}$. Also combine the emf's by adding the voltages.

$I_5 + I_{6.8} = 3I_{12}$ [1] ; $\mathscr{E}_{15} - I_5 R_5 - I_{12} R_{12} = 0$ [2] ; $\mathscr{E}_{12} - I_{12} R_{12} - I_{6.8} R_{6.8} = 0$ [3]

Use Eq. 1 to eliminate $I_{6.8}$ by $I_{6.8} = 3I_{12} - I_5$.

$\mathscr{E}_{15} - I_5 R_5 - I_{12} R_{12} = 0$ [2]

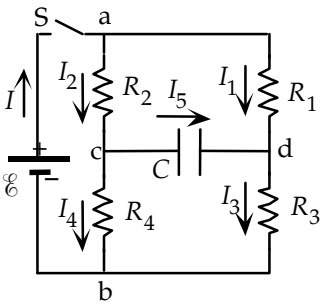
$\mathscr{E}_{12} - I_{12} R_{12} - (3I_{12} - I_5) R_{6.8} = 0$ $\rightarrow$ $\mathscr{E}_{12} - I_{12} (R_{12} + 3R_{6.8}) + I_5 R_{6.8} = 0$ [3]

Use Eq. 2 to eliminate I_5 by $I_5 = \dfrac{\mathscr{E}_{15} - I_{12} R_{12}}{R_5}$, and then solve for I_{12}.

$$\mathscr{E}_{12} - I_{12} (R_{12} + 3R_{6.8}) + \left[\frac{\mathscr{E}_{15} - I_{12} R_{12}}{R_5} \right] R_{6.8} = 0 \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_{12} = \frac{\mathscr{E}_{12}R_5 + \mathscr{E}_{15}R_{6.8}}{R_{12}R_5 + 3R_{6.8}R_5 + R_{12}R_{6.8}} = \frac{(12.00\,\text{V})(5.00\,\Omega) + (15.00\,\text{V})(6.800\,\Omega)}{(12.00\,\Omega)(5.00\,\Omega) + 3(6.800\,\Omega)(5.00\,\Omega) + (12.00\,\Omega)(6.800\,\Omega)}$$



$$= 0.66502\,\text{A} \approx \boxed{0.665\,\text{A} = I_{12}}$$

$$I_5 = \frac{\mathscr{E}_{15} - I_{12}R_{12}}{R_5} = \frac{(15.00\,\text{V}) - (0.66502\,\text{A})(12.00\,\Omega)}{(5.00\,\Omega)} = 1.40395\,\text{A} \approx \boxed{1.40\,\text{A} = I_5}$$

$$I_{6.8} = 3I_{12} - I_5 = 3(0.66502\,\text{A}) - 1.40395\,\text{A} = 0.59111\,\text{A} \approx \boxed{0.591\,\text{A} = I_{6.8}}$$

$$I_6 = 2I_{12} = 2(0.66502\,\text{A}) \approx \boxed{1.33\,\text{A} = I_6}$$

89. (*a*) After the capacitor is fully charged, there is no current through it, and so it behaves like an "open" in the circuit. In the circuit diagram, this means that $I_5 = 0$, $I_1 = I_3$, and $I_2 = I_4$. Write loop equations for the leftmost loop and the outer loop in order to solve for the currents.

$$\mathscr{E} - I_2(R_2 + R_4) = 0 \;\rightarrow\; I_2 = \frac{\mathscr{E}}{R_2 + R_4} = \frac{12.0\,\text{V}}{10.0\,\Omega} = 1.20\,\text{A}$$

$$\mathscr{E} - I_1(R_1 + R_3) = 0 \;\rightarrow\; I_1 = \frac{\mathscr{E}}{R_1 + R_3} = \frac{12.0\,\text{V}}{15.0\,\Omega} = 0.800\,\text{A}$$

Use these currents to find the voltage at points c and d, which will give the voltage across the capacitor.

$$V_c = \mathscr{E} - I_2R_2 = 12.0\,\text{V} - (1.20\,\text{A})(1.0\,\Omega) = 10.8\,\text{V}$$

$$V_d = \mathscr{E} - I_1R_1 = 12.0\,\text{V} - (0.800\,\text{A})(10.0\,\Omega) = 4.00\,\text{V}$$

$$V_{cd} = 10.8\,\text{V} - 4.00\,\text{V} = \boxed{6.8\,\text{V}}\;;\; Q = CV = (2.2\,\mu\text{F})(6.8\,\text{V}) = 14.96\,\mu\text{C} \approx \boxed{15\,\mu\text{C}}$$

(*b*) When the switch is opened, the emf is taken out of the circuit. Then we have the capacitor discharging through an equivalent resistance. That equivalent resistance is the series combination of R_1 and R_2, in parallel with the series combination of R_3 and R_4. Use the expression for discharging a capacitor, Eq. 26-9a.

$$R_{eq} = \left(\frac{1}{R_1 + R_2} + \frac{1}{R_3 + R_4}\right)^{-1} = \left(\frac{1}{11.0\,\Omega} + \frac{1}{14.0\,\Omega}\right)^{-1} = 6.16\,\Omega$$

$$Q = Q_0e^{-t/R_{eq}C} = 0.030Q_0 \;\rightarrow$$

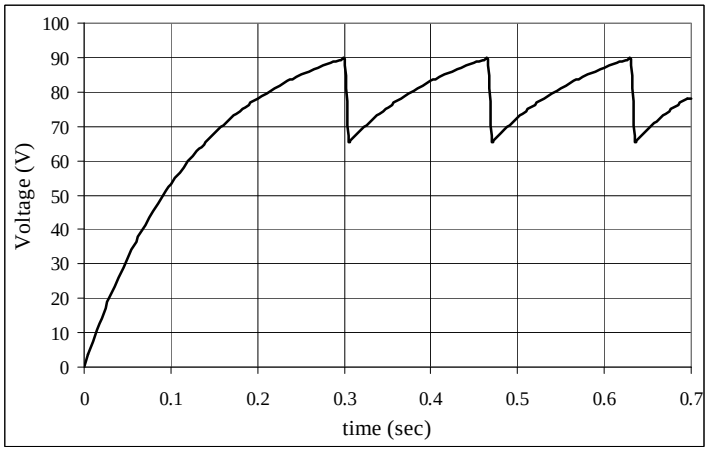
$$t = -R_{eq}C\ln(0.030) = -(6.16\,\Omega)(2.2\times10^{-6}\,\text{F})\ln(0.030) = \boxed{4.8\times10^{-5}\,\text{s}}$$

90. (*a*) The time constant of the *RC* circuit is given by Eq. 26-7.

$$\tau = RC = (33.0\text{ k}\Omega)(4.00\ \mu\text{F}) = 132\text{ ms}$$

During the charging cycle, the charge and the voltage on the capacitor increases exponentially as in Eq. 26-6b. We solve this equation for the time it takes the circuit to reach 90.0 V.

$$V = \mathscr{E}(1 - e^{-t/\tau}) \rightarrow t = -\tau\ln\left(1 - \frac{V}{\mathscr{E}}\right) = -(132\text{ ms})\ln\left(1 - \frac{90.0\text{ V}}{100.0\text{ V}}\right) = \boxed{304\text{ ms}}$$



(*b*) When the neon bulb starts conducting, the voltage on the capacitor drops quickly to 65.0 V and then starts charging. We can find the recharging time by first finding the time for the capacitor to reach 65.0 V, and then subtract that time from the time required to reach 90.0 V.

$$t = -\tau \ln\left(1 - \frac{V}{\mathscr{E}}\right) = -(132\text{ ms})\ln\left(1 - \frac{65.0\text{ V}}{100.0\text{ V}}\right) = 139\text{ ms}$$

$$\Delta t = 304\text{ ms} - 139\text{ ms} = 165\text{ ms}\ ;\ t_2 = 304\,\text{ms} + 165\,\text{ms} = \boxed{469\,\text{ms}}$$

(*c*) The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH26.XLS," on tab "Problem 26.90c."

91. We represent the 10.00-MΩ resistor by R_{10}, and the resistance of the voltmeter as R_{V}. In the first configuration, we find the equivalent resistance R_{eqA}, the current in the circuit I_{A}, and the voltage drop across R.

$$R_{\text{eqA}} = R + \frac{R_{10}R_{\text{V}}}{R_{10} + R_{\text{V}}}\ ;\ I_A = \frac{\mathscr{E}}{R_{\text{eqA}}}\ ;\ V_{\text{R}} = I_{\text{A}}R = \mathscr{E} - V_{\text{A}}\ \rightarrow\ \mathscr{E}\frac{R}{R_{\text{eqA}}} = \mathscr{E} - V_{\text{A}}$$

In the second configuration, we find the equivalent resistance R_{eqB}, the current in the circuit I_{B}, and the voltage drop across R_{10}.

$$R_{\text{eqB}} = R_{10} + \frac{RR_{\text{V}}}{R + R_{\text{V}}}\ ;\ I_B = \frac{\mathscr{E}}{R_{\text{eqB}}}\ ;\ V_{\text{R}_{10}} = I_{\text{B}}R_{10} = \mathscr{E} - V_{\text{B}}\ \rightarrow\ \mathscr{E}\frac{R_{10}}{R_{\text{eqB}}} = \mathscr{E} - V_{\text{B}}$$

We now have two equations in the two unknowns of R and R_{V}. We solve the second equation for R_{V} and substitute that into the first equation. We are leaving out much of the algebra in this solution.

$$\mathscr{E}\frac{R}{R_{\text{eqA}}} = \mathscr{E}\frac{R}{R + \dfrac{R_{10}R_{\text{V}}}{R_{10} + R_{\text{V}}}} = \mathscr{E} - V_{\text{A}}\ ;$$

$$\mathscr{E}\frac{R_{10}}{R_{\text{eqB}}} = \mathscr{E}\frac{R_{10}}{R_{10} + \dfrac{RR_{\text{V}}}{R + R_{\text{V}}}} = \mathscr{E} - V_{\text{B}}\ \rightarrow\ R_{\text{V}} = \frac{V_{\text{B}}R_{10}R}{\left(\mathscr{E}R - V_{\text{B}}R_{10} - V_{\text{B}}R\right)}$$

$$\mathscr{E} - V_{\text{A}} = \mathscr{E}\frac{R}{R + \dfrac{R_{10}R_{\text{V}}}{R_{10} + R_{\text{V}}}} = \mathscr{E}\frac{R}{R + \dfrac{R_{10}\left[\dfrac{V_{\text{B}}R_{10}R}{\left(\mathscr{E}R - V_{\text{B}}R_{10} - V_{\text{B}}R\right)}\right]}{R_{10} + \left[\dfrac{V_{\text{B}}R_{10}R}{\left(\mathscr{E}R - V_{\text{B}}R_{10} - V_{\text{B}}R\right)}\right]}}\ \rightarrow$$

$$R = \frac{V_{\text{B}}}{V_{\text{A}}}R_{10} = \frac{7.317\,\text{V}}{0.366\,\text{V}}(10.00\,\text{M}\Omega) = 199.92\,\text{M}\Omega \approx \boxed{200\,\text{M}\Omega}\ \ (3\text{ sig. fig.})$$

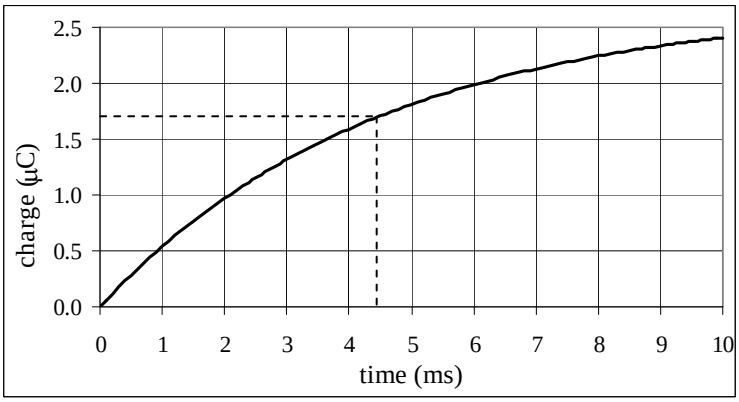
92. Let the internal resistance of the voltmeter be indicated by R_V, and let the 15-MΩ resistance be indicated by R_{15}. We calculate the current through the probe and voltmeter as the voltage across the probe divided by the equivalent resistance of the problem and the voltmeter. We then set the voltage drop across the voltmeter equal to the product of the current and the parallel combination of R_V and R_{15}. This can be solved for the unknown resistance.

$$I = \frac{V}{R + \dfrac{R_{15}R_V}{R_{15}+R_V}} \;;\; V_V = I\frac{R_{15}R_V}{R_{15}+R_V} = \frac{V}{R + \dfrac{R_{15}R_V}{R_{15}+R_V}}\frac{R_{15}R_V}{R_{15}+R_V} = \frac{VR_{15}R_V}{R\left(R_{15}+R_V\right)+R_{15}R_V} \;\rightarrow$$

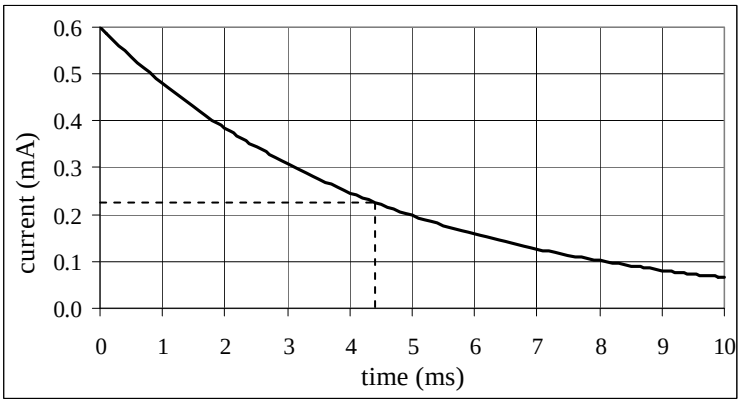
$$R = \frac{\dfrac{V}{V_V}R_{15}R_V - R_{15}R_V}{\left(R_{15}+R_V\right)} = \frac{R_{15}R_V}{\left(R_{15}+R_V\right)}\left(\frac{V}{V_V}-1\right) = \frac{(15\,\text{M}\Omega)(10\,\text{M}\Omega)}{(25\,\text{M}\Omega)}\left(\frac{50{,}000\,\text{V}}{50\,\text{V}}-1\right)$$

$$= 5994\,\text{M}\Omega \approx 6000\,\text{M}\Omega = \boxed{6\,\text{G}\Omega}$$

93. The charge and current are given by Eq. 26-6a and Eq. 26-8, respectively.



$$Q = C\mathscr{E}\left(1-e^{-t/RC}\right) \;;\; I = \frac{\mathscr{E}}{R}e^{-t/RC} \;;\; \tau = RC = \left(1.5\times10^4\,\Omega\right)\left(3.0\times10^{-7}\,\text{F}\right) = 4.5\times10^{-3}\,\text{s}$$



$$0.63Q_{\text{final}} = 0.63C\mathscr{E} = 0.63\left(3.0\times10^{-7}\,\text{F}\right)\left(9.0\,\text{V}\right) = 1.70\times10^{-6}\,\text{C}$$

$$0.37I_{\text{initial}} = 0.37\frac{\mathscr{E}}{R} = 0.37\left(\frac{9.0\,\text{V}}{1.5\times10^4\,\Omega}\right) = 2.22\times10^{-4}\,\text{A}$$

The graphs are shown. The times for the requested values are about 4.4 or 4.5 ms, about one time constant, within the accuracy of estimation on the graphs.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH26.XLS," on tab "Problem 26.93."

CHAPTER 27: Magnetism

Responses to Questions

1. The compass needle aligns itself with the local magnetic field of the Earth, and the Earth's magnetic field lines are not always parallel to the surface of the Earth.

2. The magnetic field lines are concentric circles around the wire. With the current running to the left, the field is directed counterclockwise when looking from the left end. So, the field goes into the page above the wire and comes out of the page below the wire.

3. The force is downward. The field lines point from the north pole to the south pole, or left to right. Use the right hand rule. Your fingers point in the direction of the current (away from you). Curl them in the direction of the field (to the right). Your thumb points in the direction of the force (downward).

4. $\vec{\mathbf{F}}$ is always perpendicular to both $\vec{\mathbf{B}}$ and $\vec{\ell}$. $\vec{\mathbf{B}}$ and $\vec{\ell}$ can be at any angle with respect to each other.

5. Alternating currents will have little effect on the compass needle, due to the rapid change of the direction of the current and of the magnetic field surrounding it. Direct currents will deflect a compass needle. The deflection depends on the magnitude and direction of the current and the distance from the current to the compass. The effect on the compass decreases with increasing distance from the wire.

6. The kinetic energy of the particle will stay the same. The magnetic force on the particle will be perpendicular to the particle's velocity vector and so will do no work on the particle. The force will change the direction of the particle's velocity but not the speed.

7. Positive particle in the upper left: force is downward toward the wire. Negative particle in the upper right: force is to the left. Positive particle in the lower right: force is to the left. Negative particle in the lower left: force is upward toward the wire.

8. In the areas where the particle's path is curving up towards the top of the page, the magnetic field is directed into the page. Where the particle's path curves downward towards the bottom of the page, the magnetic field is directed out of the page. Where the particle is moving in a straight line, the magnetic field direction is parallel or anti-parallel to the particle's velocity. The strength of the magnetic field is greatest where the radius of curvature of the path is the smallest.

9. (*a*) Near one pole of a very long bar magnet, the magnetic field is proportional to $1/r^2$.

   (*b*) Far from the magnet as a whole, the magnetic field is proportional to $1/r^3$.

10. The picture is created when moving charged particles hit the back of the screen. A strong magnet held near the screen can deflect the particles from their intended paths, and thus distort the picture. If the magnet is strong enough, it is possible to deflect the particles so much that they do not even reach the screen, and the picture "goes black."

11. The negative particle will curve down (toward the negative plate) if $v > E/B$ because the magnetic force (down) will be greater than the electric force (up). If $v < E/B$ the negative particle will curve up toward the positive plate because the electric force will be greater than the magnetic force. The motion of a positive particle would be exactly opposite that of a negative particle.

12. No, you cannot set a resting electron into motion with a static magnetic field. In order for a charged particle to experience a magnetic force, it must already have a velocity with a component perpendicular to the magnetic field: $F = qvB\sin\theta$. If $v = 0$, $F = 0$. Yes, you can set an electron into motion with an electric field. The electric force on a charged particle does not depend on velocity: $F = qE$.

13. The particle will move in an elongating helical path in the direction of the electric field (for a positive charge). The radius of the helix will remain constant.

14. Consider a positive ion. It will experience a force downward due to the applied electric field. Once it begins moving downward, it will then experience a force out (in the direction of the red arrow) because of its motion in the magnetic field. A negative ion will experience a force up due to the electric field and then, because it is a negative particle moving up in the magnetic field directed to the right, it will experience a force out. The positive and negative ions therefore each feel a force in the same direction.

15. The beam is deflected to the right. The current in the wire creates a magnetic field into the page surrounding the beam of electrons. This results in a magnetic force on the negative particles that is to the right.

16. Yes. One possible situation is that the magnetic field is parallel or anti-parallel to the velocity of the charged particle. In this case, the magnetic force would be zero, and the particle would continue moving in a straight line. Another possible situation is that there is an electric field with a magnitude and direction (perpendicular to the magnetic field) such that the electric and magnetic forces on the particle cancel each other out. The net force would be zero and the particle would continue moving in a straight line.

17. No. A charged particle may be deflected sideways by an electric field if a component of its velocity is perpendicular to the field.

18. If the direction of the velocity of the electrons is changing but their speed is not, then they are being deflected by a magnetic field only, and their path will be circular or helical. If the speed of the electrons is changing but the direction is not, then they are being accelerated by an electric field only. If both speed and direction are changing, the particles are possibly being deflected by both magnetic and electric fields, or they are being deflected by an electric field that is not parallel to the initial velocity of the particles. In the latter case, the component of the electron velocity antiparallel to the field direction will continue to increase, and the component of the electron velocity perpendicular to the field direction will remain constant. Therefore, the electron will asymptotically approach a straight path in the direction opposite the field direction. If the particles continue with a circular component to their path, there must be a magnetic field present.

19. Use a small current-carrying coil or solenoid for the compass needle.

20. Suspend the magnet in a known magnetic field so that it is aligned with the field and free to rotate. Measure the torque necessary to rotate the magnet so that it is perpendicular to the field lines. The magnetic moment will be the torque divided by the magnetic field strength. $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\mathbf{B}}$ so $\tau = \mu B$ when the magnetic moment and the field are perpendicular.

21. (*a*) If the plane of the current loop is perpendicular to the field such that the direction of $\vec{\mathbf{A}}$ is parallel to the field lines, the loop will be in stable equilibrium. Small displacements from this position will result in a torque that tends to return the loop to this position.
(*b*) If the plane of the current loop is perpendicular to the field such that the direction of $\vec{\mathbf{A}}$ is anti-parallel to the field lines, the loop will be in unstable equilibrium.

22. The charge carriers are positive. Positive particles moving to the right in the figure will experience a magnetic force into the page, or toward point *a*. Therefore, the positive charge carriers will tend to move toward the side containing *a*; this side will be at a higher potential than the side with point *b*.

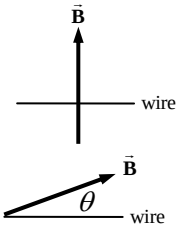
23. The distance 2*r* to the singly charged ions will be twice the distance to the doubly charged ions.

Solutions to Problems

1. (*a*) Use Eq. 27-1 to calculate the force with an angle of $90°$ and a length of 1 meter.

$$F = I\ell B\sin\theta \;\rightarrow\; \frac{F}{\ell} = IB\sin\theta = (9.40\,\text{A})(0.90\,\text{T})\sin 90° = \boxed{8.5\,\text{N/m}}$$

(*b*) $$\frac{F}{\ell} = IB\sin\theta = (9.40\,\text{A})(0.90\,\text{T})\sin 35.0° = \boxed{4.9\,\text{N/m}}$$



2. Use Eq. 27-1 to calculate the force.

$$F = I\ell B\sin\theta = (150\,\text{A})(240\,\text{m})(5.0\times10^{-5}\,\text{T})\sin 68° = \boxed{1.7\,\text{N}}$$

3. The dip angle is the angle between the Earth's magnetic field and the current in the wire. Use Eq. 27-1 to calculate the force.

$$F = I\ell B\sin\theta = (4.5\,\text{A})(1.6\,\text{m})(5.5\times10^{-5}\,\text{T})\sin 41° = \boxed{2.6\times10^{-4}\,\text{N}}$$

4. To have the maximum force, the current must be perpendicular to the magnetic field, as shown in the first diagram. Use $\frac{F}{\ell} = 0.25\frac{F_{\text{max}}}{\ell}$ to find the angle between the wire and the magnetic field, illustrated in the second diagram.

$$\frac{F}{\ell} = 0.25\frac{F_{\text{max}}}{\ell} \;\rightarrow\; IB\sin\theta = 0.25IB \;\rightarrow\; \theta = \sin^{-1}0.25 = \boxed{14°}$$

5. (*a*) By the right hand rule, the magnetic field must be pointing up, and so the top pole face must be a South pole .
(*b*) Use Eq. 27-2 to relate the maximum force to the current. The length of wire in the magnetic field is equal to the diameter of the pole faces.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$F_{\max} = I\ell B \;\rightarrow\; I = \frac{F_{\max}}{\ell B} = \frac{\left(7.50\times10^{-2}\,\text{N}\right)}{\left(0.100\,\text{m}\right)\left(0.220\,\text{T}\right)} = 3.4091\,\text{A} \approx \boxed{3.41\,\text{A}}$$

(*c*) Multiply the maximum force by the sine of the angle between the wire and the magnetic field.

$$F = F_{\max}\sin\theta = \left(7.50\times10^{-2}\,\text{N}\right)\sin 80.0° = \boxed{7.39\times10^{-2}\,\text{N}}$$

6. The magnetic force must be equal in magnitude to the force of gravity on the wire. The maximum magnetic force is applicable since the wire is perpendicular to the magnetic field. The mass of the wire is the density of copper times the volume of the wire.

$$F_{\text{B}} = mg \;\rightarrow\; I\ell B = \rho\pi\left(\tfrac{1}{2}d\right)^2 \ell g \;\rightarrow$$

$$I = \frac{\rho\pi d^2 g}{4B} = \frac{\left(8.9\times10^3\,\text{kg/m}^3\right)\pi\left(1.00\times10^{-3}\,\text{m}\right)^2\left(9.80\,\text{m/s}^2\right)}{4\left(5.0\times10^{-5}\,\text{T}\right)} = \boxed{1400\,\text{A}}$$

This answer does not seem feasible. The current is very large, and the resistive heating in the thin copper wire would probably melt it.

7. We find the force using Eq. 27-3, where the vector length is broken down into two parts: the portion along the z-axis and the portion along the line *y=2x*.

$$\vec{\boldsymbol{\ell}}_1 = -0.250\,\text{m}\,\hat{\mathbf{k}} \qquad \vec{\boldsymbol{\ell}}_2 = 0.250\,\text{m}\left(\frac{\hat{\mathbf{i}}+2\hat{\mathbf{j}}}{\sqrt{5}}\right)$$

$$\vec{\mathbf{F}} = I\vec{\boldsymbol{\ell}}\times\vec{\mathbf{B}} = I\left(\vec{\boldsymbol{\ell}}_1+\vec{\boldsymbol{\ell}}_2\right)\times\vec{\mathbf{B}} = \left(20.0\,\text{A}\right)\left(0.250\,\text{m}\right)\left(-\hat{\mathbf{k}}+\frac{\hat{\mathbf{i}}+2\hat{\mathbf{j}}}{\sqrt{5}}\right)\times\left(0.318\hat{\mathbf{i}}\,\text{T}\right)$$

$$= \left(1.59\ \text{N}\right)\left(-\hat{\mathbf{k}}\times\hat{\mathbf{i}}+\frac{2}{\sqrt{5}}\hat{\mathbf{j}}\times\hat{\mathbf{i}}\right) = -\left(1.59\hat{\mathbf{j}}+1.42\hat{\mathbf{k}}\right)\text{N}$$

$$F = \left|\vec{\mathbf{F}}\right| = \sqrt{1.59^2+1.42^2}\ \text{N} = \boxed{2.13\ \text{N}}$$

$$\theta = \tan^{-1}\left(\frac{-1.42\ \text{N}}{-1.59\ \text{N}}\right) = \boxed{41.8°\text{ below the negative y-axis}}$$

8. We find the force per unit length from Eq. 27-3. Note that while the length is not known, the direction is given, and so $\vec{\boldsymbol{\ell}} = \ell\hat{\mathbf{i}}$.

$$\vec{\mathbf{F}}_{\text{B}} = I\vec{\boldsymbol{\ell}}\times\vec{\mathbf{B}} = I\ell\hat{\mathbf{i}}\times\vec{\mathbf{B}} \;\rightarrow$$

$$\frac{\vec{\mathbf{F}}_{\text{B}}}{\ell} = I\,\hat{\mathbf{i}}\times\vec{\mathbf{B}} = \left(3.0\,\text{A}\right)\begin{vmatrix}\hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}}\\ 1 & 0 & 0\\ 0.20\,\text{T} & -0.36\,\text{T} & 0.25\,\text{T}\end{vmatrix} = \left(-0.75\hat{\mathbf{j}}-1.08\hat{\mathbf{k}}\right)\text{N/m}\left(\frac{1\,\text{m}}{100\,\text{cm}}\right)$$

$$= \boxed{-\left(7.5\hat{\mathbf{j}}+11\hat{\mathbf{k}}\right)\times10^{-3}\,\text{N/cm}}$$

9. We find the net force on the loop by integrating the infinitesimal force on each infinitesimal portion of the loop within the magnetic field. The infinitesimal force is found using Eq. 27-4 with the current in an infinitesimal portion of the loop given by $Id\vec{\boldsymbol{\ell}} = I\left(-\cos\theta\hat{\mathbf{i}}+\sin\theta\hat{\mathbf{j}}\right)rd\theta$.

$$\vec{\mathbf{F}} = \int Id\vec{\boldsymbol{\ell}}\times\vec{B} = I\int_{\theta_0}^{2\pi-\theta_0}\left(-\cos\theta\hat{\mathbf{i}}+\sin\theta\hat{\mathbf{j}}\right)rd\theta\times B_0\hat{\mathbf{k}} = IB_0r\int_{\theta_0}^{2\pi-\theta_0}\left(\cos\theta\hat{\mathbf{j}}+\sin\theta\hat{\mathbf{i}}\right)d\theta$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= IB_0 r\left(\sin\theta\hat{\mathbf{j}} - \cos\theta\hat{\mathbf{i}}\right)\Big|_{\theta_0}^{2\pi-\theta_0} = IB_0 r\left[\sin\left(2\pi-\theta_0\right)\hat{\mathbf{j}} - \sin\theta_0\hat{\mathbf{j}} - \cos\left(2\pi-\theta_0\right)\hat{\mathbf{i}} + \cos\theta_0\hat{\mathbf{i}}\right]$$

$$= \boxed{-2IB_0 r\sin\theta_0\hat{\mathbf{j}}}$$

The trigonometric identities $\sin\left(2\pi-\theta\right) = -\sin\theta$ and $\cos\left(2\pi-\theta\right) = \cos\theta$ are used to simplify the solution.

10. We apply Eq. 27-3 to each circumstance, and solve for the magnetic field. Let $\vec{\mathbf{B}} = B_x\hat{\mathbf{i}} + B_y\hat{\mathbf{j}} + B_z\hat{\mathbf{k}}$.

For the first circumstance, $\vec{\boldsymbol{\ell}} = \ell\hat{\mathbf{i}}$.

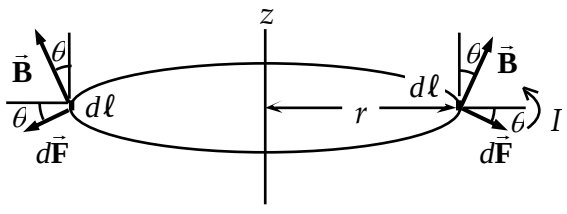
$$\vec{\mathbf{F}}_B = I\vec{\boldsymbol{\ell}}\times\vec{\mathbf{B}} = \left(8.2\,\text{A}\right)\begin{vmatrix}\hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}}\\ 2.0\,\text{m} & 0 & 0\\ B_x & B_y & B_z\end{vmatrix} = \left(-16.4\,\text{A•m}\right)B_z\hat{\mathbf{j}} + \left(16.4\,\text{A•m}\right)B_y\hat{\mathbf{k}} = \left(-2.5\hat{\mathbf{j}}\right)\text{N} \;\rightarrow$$

$$B_y = 0\,;\ \left(-16.4\,\text{A•m}\right)B_z = -2.5\,\text{N} \;\rightarrow\; B_z = \frac{2.5\,\text{N}}{16.4\,\text{A•m}} = 0.1524\,\text{T}\,;\ \ B_x \text{ unknown}$$

For the second circumstance, $\vec{\boldsymbol{\ell}} = \ell\hat{\mathbf{j}}$.

$$\vec{\mathbf{F}}_B = I\vec{\boldsymbol{\ell}}\times\vec{\mathbf{B}} = \left(8.2\,\text{A}\right)\begin{vmatrix}\hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}}\\ 0 & 2.0\,\text{m} & 0\\ B_x & 0 & 0.1524\,\text{T}\end{vmatrix} = \left(2.5\,\text{N}\right)\hat{\mathbf{i}} + \left(-16.4\,\text{A•m}\right)B_x\hat{\mathbf{k}} = \left(2.5\hat{\mathbf{i}} - 5.0\hat{\mathbf{k}}\right)\text{N} \;\rightarrow$$

$$\left(-16.4\,\text{A•m}\right)B_x = -5.0\,\text{N} \;\rightarrow\; B_x = \frac{5.0\,\text{N}}{16.4\,\text{A•m}} = 0.3049\,\text{T}$$



Thus $\vec{\mathbf{B}} = \boxed{\left(0.30\hat{\mathbf{i}} + 0.15\hat{\mathbf{k}}\right)\text{T}}$.

11. We find the force along the wire by integrating the infinitesimal force from each path element (given by Eq. 27-4) along an arbitrary path between the points *a* and *b*.

$$\vec{\mathbf{F}} = \int_a^b Id\vec{\boldsymbol{\ell}}\times\vec{\mathbf{B}} = I\int_a^b\left(\hat{\mathbf{i}}dx + \hat{\mathbf{j}}dy\right)\times B_0\hat{\mathbf{k}} = IB_0\int_a^b\left(-\hat{\mathbf{j}}dx + \hat{\mathbf{i}}dy\right) = IB_0\left(-\Delta x\hat{\mathbf{j}} + \Delta y\hat{\mathbf{i}}\right)$$

The resultant magnetic force on the wire depends on the displacement between the points *a* and *b*, and not on the path taken by the wire. Therefore, the resultant force must be the same for the curved path, as for the straight line path between the points.

12. The net force on the current loop is the sum of the infinitesimal forces obtained from each current element. From the figure, we see that at each current segment, the magnetic field is perpendicular to the current. This results in a force with only radial and vertical components. By symmetry, we find that the radial force components from segments on opposite sides of the loop cancel. The net force then is purely vertical. Symmetry also shows us that each current element contributes the same magnitude of force.

$$\vec{\mathbf{F}} = \int Id\vec{\boldsymbol{\ell}}\times B = -IB_r\hat{\mathbf{k}}\int d\ell = -I\left(B\sin\theta\right)\hat{\mathbf{k}}\left(2\pi r\right) = \boxed{-2\pi IB\frac{r^2}{\sqrt{r^2+d^2}}\hat{\mathbf{k}}}$$

13. The maximum magnetic force as given in Eq. 27-5b can be used since the velocity is perpendicular to the magnetic field.

$$F_{\max} = qvB = \left(1.60\times10^{-19}\,\text{C}\right)\left(8.75\times10^{5}\,\text{m/s}\right)\left(0.45\,\text{T}\right) = \boxed{6.3\times10^{-14}\,\text{N}}$$

By the right hand rule, the force must be directed to the **North**.

14. The magnetic force will cause centripetal motion, and the electron will move in a clockwise circular path if viewed in the direction of the magnetic field. The radius of the motion can be determined.

$$F_{\max} = qvB = m\frac{v^2}{r} \quad\rightarrow\quad r = \frac{mv}{qB} = \frac{\left(9.11\times10^{-31}\,\text{kg}\right)\left(1.70\times10^{6}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.480\,\text{T}\right)} = \boxed{2.02\times10^{-5}\,\text{m}}$$

15. In this scenario, the magnetic force is causing centripetal motion, and so must have the form of a centripetal force. The magnetic force is perpendicular to the velocity at all times for circular motion.

$$F_{\max} = qvB = m\frac{v^2}{r} \quad\rightarrow\quad B = \frac{mv}{qr} = \frac{\left(6.6\times10^{-27}\,\text{kg}\right)\left(1.6\times10^{7}\,\text{m/s}\right)}{2\left(1.60\times10^{-19}\,\text{C}\right)\left(0.18\,\text{m}\right)} = \boxed{1.8\,\text{T}}$$

16. Since the charge is negative, the answer is the OPPOSITE of the result given from the right hand rule applied to the velocity and magnetic field.
(*a*) left
(*b*) left
(*c*) upward
(*d*) inward into the paper
(*e*) no force
(*f*) downward

17. The right hand rule applied to the velocity and magnetic field would give the direction of the force. Use this to determine the direction of the magnetic field given the velocity and the force.
(*a*) downward
(*b*) inward into the paper
(*c*) right

18. The force on the electron due to the electric force must be the same magnitude as the force on the electron due to the magnetic force.

$$F_{\text{E}} = F_{\text{B}} \quad\rightarrow\quad qE = qvB \quad\rightarrow\quad v = \frac{E}{B} = \frac{8.8\times10^{3}\,\text{V/m}}{7.5\times10^{-3}\,\text{T}} = 1.173\times10^{6}\,\text{m/s} \approx \boxed{1.2\times10^{6}\,\text{m/s}}$$

If the electric field is turned off, the magnetic force will cause circular motion.

$$F_{\text{B}} = qvB = m\frac{v^2}{r} \quad\rightarrow\quad r = \frac{mv}{qB} = \frac{\left(9.11\times10^{-31}\,\text{kg}\right)\left(1.173\times10^{6}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{C}\right)\left(7.5\times10^{-3}\,\text{T}\right)} = \boxed{8.9\times10^{-4}\,\text{m}}$$

19. (*a*) The velocity of the ion can be found using energy conservation. The electrical potential energy of the ion becomes kinetic energy as it is accelerated. Then, since the ion is moving perpendicular to the magnetic field, the magnetic force will be a maximum. That force will cause the ion to move in a circular path.

$$E_{\text{initial}} = E_{\text{final}} \quad\rightarrow\quad qV = \tfrac{1}{2}mv^2 \quad\rightarrow\quad v = \sqrt{\frac{2qV}{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$F_{\max} = qvB = m\frac{v^2}{r} \quad \rightarrow$$

$$r = \frac{mv}{qB} = \frac{m\sqrt{\dfrac{2qV}{m}}}{qB} = \frac{1}{B}\sqrt{\frac{2mV}{q}} = \frac{1}{0.340\,\text{T}}\sqrt{\frac{2\left(6.6\times10^{-27}\,\text{kg}\right)\left(2700\,\text{V}\right)}{2\left(1.60\times10^{-19}\,\text{C}\right)}} = \boxed{3.1\times10^{-2}\,\text{m}}$$

(*b*) The period can be found from the speed and the radius. Use the expressions for the radius and the speed from above.

$$v = \frac{2\pi r}{T} \quad \rightarrow \quad T = \frac{2\pi r}{v} = \frac{2\pi\dfrac{1}{B}\sqrt{\dfrac{2mV}{q}}}{\sqrt{\dfrac{2qV}{m}}} = \frac{2\pi m}{qB} = \frac{2\pi\left(6.6\times10^{-27}\,\text{kg}\right)}{2\left(1.60\times10^{-19}\,\text{C}\right)\left(0.340\,\text{T}\right)} = \boxed{3.8\times10^{-7}\,\text{s}}$$

20. The velocity of each charged particle can be found using energy conservation. The electrical potential energy of the particle becomes kinetic energy as it is accelerated. Then, since the particle is moving perpendicularly to the magnetic field, the magnetic force will be a maximum. That force will cause the ion to move in a circular path, and the radius can be determined in terms of the mass and charge of the particle.

$$E_{\text{initial}} = E_{\text{final}} \quad \rightarrow \quad qV = \tfrac{1}{2}mv^2 \quad \rightarrow \quad v = \sqrt{\frac{2qV}{m}}$$

$$F_{\max} = qvB = m\frac{v^2}{r} \quad \rightarrow \quad r = \frac{mv}{qB} = \frac{m\sqrt{\dfrac{2qV}{m}}}{qB} = \frac{1}{B}\sqrt{\frac{2mV}{q}}$$

$$\frac{r_{\text{d}}}{r_{\text{p}}} = \frac{\dfrac{1}{B}\sqrt{\dfrac{2m_{\text{d}}V}{q_{\text{d}}}}}{\dfrac{1}{B}\sqrt{\dfrac{2m_{\text{p}}V}{q_{\text{p}}}}} = \frac{\sqrt{\dfrac{m_{\text{d}}}{m_{\text{p}}}}}{\sqrt{\dfrac{q_{\text{d}}}{q_{\text{p}}}}} = \frac{\sqrt{2}}{\sqrt{1}} = \sqrt{2} \quad \rightarrow \quad \boxed{r_{\text{d}} = \sqrt{2}r_{\text{p}}}$$

$$\frac{r_{\alpha}}{r_{\text{p}}} = \frac{\dfrac{1}{B}\sqrt{\dfrac{2m_{\alpha}V}{q_{\alpha}}}}{\dfrac{1}{B}\sqrt{\dfrac{2m_{\text{p}}V}{q_{\text{p}}}}} = \frac{\sqrt{\dfrac{m_{\alpha}}{m_{\text{p}}}}}{\sqrt{\dfrac{q_{\alpha}}{q_{\text{p}}}}} = \frac{\sqrt{4}}{\sqrt{2}} = \sqrt{2} \quad \rightarrow \quad \boxed{r_{\alpha} = \sqrt{2}r_{\text{p}}}$$

21. (*a*) From Example 27-7, we have that $r = \dfrac{mv}{qB}$, and so $v = \dfrac{rqB}{m}$. The kinetic energy is given by

$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m\left(\dfrac{rqB}{m}\right)^2 = \dfrac{r^2q^2B^2}{2m}$ and so we see that $\boxed{K \propto r^2}$.

(*b*) The angular momentum of a particle moving in a circular path is given by $L = mvr$. From Example 27-7, we have that $r = \dfrac{mv}{qB}$, and so $v = \dfrac{rqB}{m}$. Combining these relationships gives

$$L = mvr = m\frac{rqB}{m}r = \boxed{qBr^2}.$$

22. The force on the electron is given by Eq. 27-5a.

$$\vec{\mathbf{F}}_B = q\vec{\mathbf{v}}\times\vec{\mathbf{B}} = -e\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 7.0\times10^4\ \text{m/s} & -6.0\times10^4\ \text{m/s} & 0 \\ -0.80\,\text{T} & 0.60\,\text{T} & 0 \end{vmatrix} = -e\left(4.2-4.8\right)\times10^4\ \text{T•m/s}\,\hat{\mathbf{k}}$$

$$= -\left(1.60\times10^{-19}\,\text{C}\right)\left(-0.6\times10^4\ \text{T•m/s}\,\hat{\mathbf{k}}\right) = 9.6\times10^{-16}\,\text{N}\,\hat{\mathbf{k}} \approx \boxed{1\times10^{-15}\,\text{N}\,\hat{\mathbf{k}}}$$

23. The kinetic energy of the proton can be used to find its velocity. The magnetic force produces centripetal acceleration, and from this the radius can be determined.

$$K = \tfrac{1}{2}mv^2 \;\rightarrow\; v = \sqrt{\frac{2K}{m}} \qquad qvB = \frac{mv^2}{r} \;\rightarrow\; r = \frac{mv}{qB}$$

$$r = \frac{mv}{qB} = \frac{m\sqrt{\dfrac{2K}{m}}}{qB} = \frac{\sqrt{2Km}}{qB} = \frac{\sqrt{2\left(6.0\times10^6\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)\left(1.67\times10^{-27}\,\text{kg}\right)}}{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.20\,\text{T}\right)} = \boxed{1.8\,\text{m}}$$

24. The magnetic field can be found from Eq. 27-5b, and the direction is found from the right hand rule. Remember that the charge is negative.

$$F_{\max} = qvB \;\rightarrow\; B = \frac{F_{\max}}{qv} = \frac{8.2\times10^{-13}\,\text{N}}{\left(1.60\times10^{-19}\,\text{C}\right)\left(2.8\times10^6\ \text{m/s}\right)} = \boxed{1.8\,\text{T}}$$

The direction would have to be $\boxed{\text{East}}$ for the right hand rule, applied to the velocity and the magnetic field, to give the proper direction of force.

25. The total force on the proton is given by the Lorentz equation, Eq. 27-7.

$$\vec{\mathbf{F}}_B = q\left(\vec{\mathbf{E}}+\vec{\mathbf{v}}\times\vec{\mathbf{B}}\right) = e\left[\left(3.0\hat{\mathbf{i}}-4.2\hat{\mathbf{j}}\right)\times10^3\ \text{V/m} + \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 6.0\times10^3\ \text{m/s} & 3.0\times10^3\ \text{m/s} & -5.0\times10^3\ \text{m/s} \\ 0.45\,\text{T} & 0.38\,\text{T} & 0 \end{vmatrix}\right]$$

$$= \left(1.60\times10^{-19}\,\text{C}\right)\left[\left(3.0\hat{\mathbf{i}}-4.2\hat{\mathbf{j}}\right)+\left(1.9\hat{\mathbf{i}}-2.25\hat{\mathbf{j}}+0.93\hat{\mathbf{k}}\right)\right]\times10^3\ \text{N/C}$$

$$= \left(1.60\times10^{-19}\,\text{C}\right)\left[\left(4.9\hat{\mathbf{i}}-6.45\hat{\mathbf{j}}+0.93\hat{\mathbf{k}}\right)\right]\times10^3\ \text{N/C}$$

$$= \left(7.84\times10^{-16}\hat{\mathbf{i}}-1.03\times10^{-15}\hat{\mathbf{j}}+1.49\times10^{-16}\hat{\mathbf{k}}\right)\text{N/C}$$

$$= \boxed{\left[\left(0.78\hat{\mathbf{i}}-1.0\hat{\mathbf{j}}+0.15\hat{\mathbf{k}}\right)\right]\times10^{-15}\,\text{N}}$$

26. The force on the electron is given by Eq. 27-5a. Set the force expression components equal and solve for the velocity components.

$$\vec{\mathbf{F}}_B = q\vec{\mathbf{v}}\times\vec{\mathbf{B}} \;\rightarrow\; F_x\hat{\mathbf{i}}+F_y\hat{\mathbf{j}} = -e\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ v_x & v_y & v_z \\ 0 & 0 & B_z \end{vmatrix} = -ev_yB_z\hat{\mathbf{i}} - e\left(-v_xB_z\right)\hat{\mathbf{j}} \;\rightarrow$$

$$F_x = -ev_yB_z \;\rightarrow\; v_y = -\frac{F_x}{eB_z} = -\frac{3.8\times10^{-13}\,\text{N}}{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.85\text{T}\right)} = -2.8\times10^6\ \text{m/s}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$F_y = ev_x B_z \quad \rightarrow \quad v_x = \frac{F_y}{eB_z} = \frac{-2.7\times10^{-13}\,\text{N}}{(1.60\times10^{-19}\,\text{C})(0.85\text{T})} = -2.0\times10^{6}\,\text{m/s}$$

$$\vec{\mathbf{v}} = \boxed{-\left(2.0\hat{\mathbf{i}} + 2.8\hat{\mathbf{j}}\right)\times10^{6}\,\text{m/s}}$$

Notice that we have not been able to determine the *z* component of the electron's velocity.

27. The kinetic energy of the particle can be used to find its velocity. The magnetic force produces centripetal acceleration, and from this the radius can be determined. Inserting the radius and velocity into the equation for angular momentum gives the angular momentum in terms of the kinetic energy and magnetic field.

$$K = \tfrac{1}{2}mv^2 \quad \rightarrow \quad v = \sqrt{\frac{2K}{m}} \qquad qvB = \frac{mv^2}{r} \quad \rightarrow \quad r = \frac{mv}{qB}$$

$$L = mvr = m\sqrt{\frac{2K}{m}}\left(\frac{m\sqrt{\frac{2K}{m}}}{qB}\right) = \frac{2mK}{qB}$$

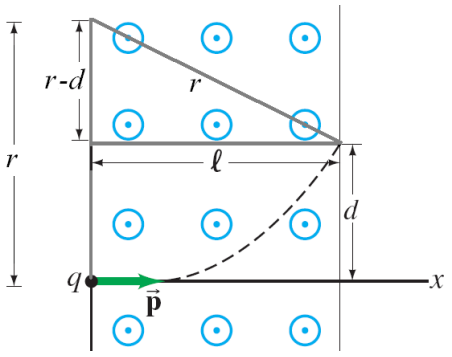
From the equation for the angular momentum, we see that doubling the magnetic field while keeping the kinetic energy constant will cut the angular momentum in half.

$$\boxed{L_{\text{final}} = \tfrac{1}{2}L_{\text{initial}}}$$

28. The centripetal force is caused by the magnetic field, and is given by Eq. 27-5b.

$$F = qvB\sin\theta = qv_\perp B = m\frac{v_\perp^2}{r} \quad \rightarrow$$

$$r = \frac{mv_\perp}{qB} = \frac{(9.11\times10^{-31}\,\text{kg})(3.0\times10^{6}\,\text{m/s})\sin45^\circ}{(1.60\times10^{-19}\,\text{C})(0.28\,\text{T})} = 4.314\times10^{-5}\,\text{m} \approx \boxed{4.3\times10^{-5}\,\text{m}}$$



The component of the velocity that is parallel to the magnetic field is unchanged, and so the pitch is that velocity component times the period of the circular motion.

$$T = \frac{2\pi r}{v_\perp} = \frac{2\pi\dfrac{mv_\perp}{qB}}{v_\perp} = \frac{2\pi m}{qB}$$

$$p = v_\parallel T = v\cos45^\circ\left(\frac{2\pi m}{qB}\right) = (3.0\times10^{6}\,\text{m/s})\cos45^\circ\frac{2\pi(9.11\times10^{-31}\,\text{kg})}{(1.60\times10^{-19}\,\text{C})(0.28\,\text{T})} = \boxed{2.7\times10^{-4}\,\text{m}}$$

29. (*a*) For the particle to move upward the magnetic force must point upward, by the right hand rule we see that the force on a positively charged particle would be downward. Therefore, the charge on the particle must be negative.

(*b*) In the figure we have created a right triangle to relate the horizontal distance ℓ, the displacement *d*, and the radius of curvature, *r*. Using the Pythagorean theorem we can write an expression for the radius in terms of the other two distances.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$r^2 = (r-d)^2 + \ell^2 \rightarrow r = \frac{d^2 + \ell^2}{2d}$$

Since the momentum is perpendicular to the magnetic field, we can solve for the momentum by relating the maximum force (Eq. 27-5b) to the centripetal force on the particle.

$$F_{\max} = qvB_0 = \frac{mv^2}{r} \rightarrow p = mv = qB_0 r = \boxed{\frac{qB_0\left(d^2 + \ell^2\right)}{2d}}$$

30. In order for the path to be bent by 90° within a distance d, the radius of curvature must be less than or equal to d. The kinetic energy of the protons can be used to find their velocity. The magnetic force produces centripetal acceleration, and from this, the magnetic field can be determined.

$$K = \tfrac{1}{2}mv^2 \rightarrow v = \sqrt{\frac{2K}{m}} \qquad qvB = \frac{mv^2}{r} \rightarrow B = \frac{mv}{qr}$$

$$B \geq \frac{mv}{ed} = \frac{m\sqrt{\frac{2K}{m}}}{ed} = \boxed{\left(\frac{2Km}{e^2 d^2}\right)^{1/2}}$$

31. The magnetic force will produce centripetal acceleration. Use that relationship to calculate the speed. The radius of the Earth is $6.38\times10^6\,\text{km}$, and the altitude is added to that.

$$F_B = qvB = m\frac{v^2}{r} \rightarrow v = \frac{qrB}{m} = \frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(6.385\times10^6\,\text{m}\right)\left(0.50\times10^{-4}\,\text{T}\right)}{238\left(1.66\times10^{-27}\,\text{kg}\right)} = \boxed{1.3\times10^8\,\text{m/s}}$$

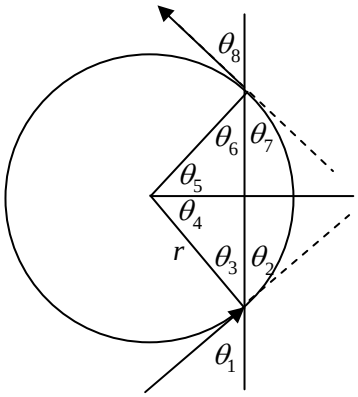
Compare the size of the magnetic force to the force of gravity on the ion.

$$\frac{F_B}{F_g} = \frac{qvB}{mg} = \frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(1.3\times10^8\,\text{m/s}\right)\left(0.50\times10^{-4}\,\text{T}\right)}{238\left(1.66\times10^{-27}\,\text{kg}\right)\left(9.80\,\text{m/s}^2\right)} = 2.3\times10^8$$

Yes, we may ignore gravity. The magnetic force is more than 200 million times larger than gravity.

32. The magnetic force produces an acceleration that is perpendicular to the original motion. If that perpendicular acceleration is small, it will produce a small deflection, and the original velocity can be assumed to always be perpendicular to the magnetic field. This leads to a constant perpendicular acceleration. The time that this (approximately) constant acceleration acts can be found from the original velocity v and the distance traveled ℓ. The starting speed in the perpendicular direction will be zero.

$$F_\perp = ma_\perp = qvB \rightarrow a_\perp = \frac{qvB}{m}$$



$$d_\perp = v_{0\perp}t + \tfrac{1}{2}a_\perp t^2 = \tfrac{1}{2}\frac{qvB}{m}\left(\frac{\ell}{v}\right)^2 = \frac{qB\ell^2}{2mv} = \frac{\left(18.5\times10^{-9}\,\text{C}\right)\left(5.00\times10^{-5}\,\text{T}\right)\left(1.00\times10^3\,\text{m}\right)^2}{2\left(3.40\times10^{-3}\,\text{kg}\right)\left(155\,\text{m/s}\right)}$$

$$= \boxed{8.8\times10^{-7}\,\text{m}}$$

This small distance justifies the assumption of constant acceleration.

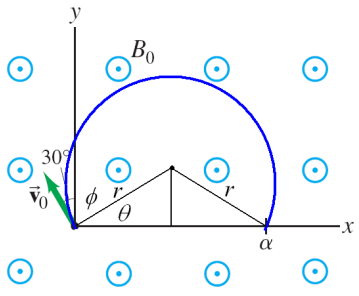
33. (*a*) In the magnetic field, the proton will move along an arc of a circle. The distance *x* in the diagram is a chord of that circle, and so the center of the circular path lies on the perpendicular bisector of the chord. That perpendicular bisector bisects the central angle of the circle which subtends the chord. Also recall that a radius is perpendicular to a tangent. In the diagram, $\theta_1 = \theta_2$ because they are vertical angles. Then $\theta_2 = \theta_4$, because they are both complements of θ_3, so $\theta_1 = \theta_4$. We have $\theta_4 = \theta_5$ since the central angle is bisected by the perpendicular bisector of the chord. $\theta_5 = \theta_7$ because they are both complements of θ_6, and $\theta_7 = \theta_8$ because they are vertical angles. Thus $\theta_1 = \theta_2 = \theta_4 = \theta_5 = \theta_7 = \theta_8$, and so in the textbook diagram, the angle at which the proton leaves is $\boxed{\theta = 45^\circ}$.



(*b*) The radius of curvature is given by $r = \dfrac{mv}{qB}$, and the distance *x* is twice the value of $r\cos\theta$.

$$x = 2r\cos\theta = 2\frac{mv}{qB}\cos\theta = 2\frac{\left(1.67\times10^{-27}\,\text{kg}\right)\left(1.3\times10^{5}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.850\,\text{T}\right)}\cos 45^\circ = \boxed{2.3\times10^{-3}\,\text{m}}$$

34. (*a*) Since the velocity is perpendicular to the magnetic field, the particle will follow a circular trajectory in the *x*-*y* plane of radius *r*. The radius is found using the centripetal acceleration.

$$qvB = \frac{mv^2}{r} \quad \rightarrow \quad r = \frac{mv}{qB}$$

From the figure we see that the distance α is the chord distance, which is twice the distance $r\cos\theta$. Since the velocity is perpendicular to the radial vector, the initial direction and the angle ϕ are complementary angles. The angles ϕ and θ are also complementary angles, so $\theta = 30°$.

$$\alpha = 2r\cos\theta = \frac{2mv_0}{qB_0}\cos 30^\circ = \boxed{\sqrt{3}\frac{mv_0}{qB_0}}$$

(*b*) From the diagram, we see that the particle travels a circular path, that is 2ϕ short of a complete circle. Since the angles ϕ and θ are complementary angles, so $\phi = 60°$. The trajectory distance is equal to the circumference of the circular path times the fraction of the complete circle. Dividing the distance by the particle speed gives t_α.

$$t_\alpha = \frac{\ell}{v_0} = \frac{2\pi r}{v_0}\left(\frac{360^\circ - 2(60^\circ)}{360^\circ}\right) = \frac{2\pi}{v_0}\frac{mv_0}{qB_0}\left(\frac{2}{3}\right) = \boxed{\frac{4\pi m}{3qB_0}}$$

35. The work required by an external agent is equal to the change in potential energy. The potential energy is given by Eq. 27-12, $U = -\vec{\boldsymbol{\mu}}\cdot\vec{\mathbf{B}}$.

(*a*) $W = \Delta U = \left(-\vec{\boldsymbol{\mu}}\cdot\vec{\mathbf{B}}\right)_{\text{final}} - \left(-\vec{\boldsymbol{\mu}}\cdot\vec{\mathbf{B}}\right)_{\text{initial}} = \left(\vec{\boldsymbol{\mu}}\cdot\vec{\mathbf{B}}\right)_{\text{initial}} - \left(\vec{\boldsymbol{\mu}}\cdot\vec{\mathbf{B}}\right)_{\text{final}} = NIAB\left(\cos\theta_{\text{initial}} - \cos\theta_{\text{final}}\right)$

$= NIAB\left(\cos 0^\circ - \cos 180^\circ\right) = \boxed{2NIAB}$

(*b*) $W = NIAB\left(\cos\theta_{\text{initial}} - \cos\theta_{\text{final}}\right) = NIAB\left(\cos 90^\circ - \cos\left(-90^\circ\right)\right) = \boxed{0}$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

36. With the plane of the loop parallel to the magnetic field, the torque will be a maximum. We use Eq. 27-9.

$$\tau = NIAB\sin\theta \;\rightarrow\; B = \frac{\tau}{NIAB\sin\theta} = \frac{0.185\,\text{m•N}}{(1)(4.20\,\text{A})\pi(0.0650\,\text{m})^2\sin 90^\circ} = \boxed{3.32\,\text{T}}$$

37. (*a*) The torque is given by Eq. 27-9. The angle is the angle between the B-field and the perpendicular to the coil face.

$$\tau = NIAB\sin\theta = 12(7.10\,\text{A})\left[\pi\left(\frac{0.180\,\text{m}}{2}\right)^2\right](5.50\times10^{-5}\,\text{T})\sin 24^\circ = \boxed{4.85\times10^{-5}\,\text{m•N}}$$

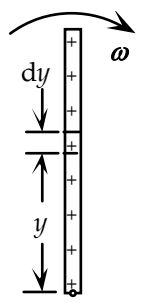
(*b*) In Example 27-11 it is stated that if the coil is free to turn, it will rotate toward the orientation so that the angle is 0. In this case, that means the north edge of the coil will rise, so that a perpendicular to its face will be parallel with the Earth's magnetic field.

38. The magnetic dipole moment is defined in Eq. 27-10 as $\mu = NIA$. The number of turns, N, is 1. The current is the charge per unit time passing a given point, which on the average is the charge on the electron divided by the period of the circular motion, $I = e/T$. If we assume the electron is moving in a circular orbit of radius *r*, then the area is πr^2. The period of the motion is the circumference of the orbit divided by the speed, $T = 2\pi r/v$. Finally, the angular momentum of an object moving in a circle is given by $L = mrv$. Combine these relationships to find the magnetic moment.

$$\mu = NIA = \frac{e}{T}\pi r^2 = \frac{e}{2\pi r/v}\pi r^2 = \frac{e\pi r^2 v}{2\pi r} = \frac{erv}{2} = \frac{emrv}{2m} = \frac{e}{2m}mrv = \frac{e}{2m}L$$

39. (*a*) The magnetic moment of the coil is given by Eq. 27-10. Since the current flows in the clockwise direction, the right hand rule shows that the magnetic moment is down, or in the negative *z*-direction.

$$\vec{\boldsymbol{\mu}} = NI\vec{\mathbf{A}} = 15(7.6\,\text{A})\pi\left(\frac{0.22\,\text{m}}{2}\right)^2(-\hat{\mathbf{k}}) = -4.334\,\hat{\mathbf{k}}\,\text{A•m}^2 \approx \boxed{-4.3\hat{\mathbf{k}}\,\text{A•m}^2}$$



(*b*) We use Eq. 27-11 to find the torque on the coil.

$$\vec{\tau} = \vec{\boldsymbol{\mu}}\times\vec{\mathbf{B}} = \left(-4.334\;\hat{\mathbf{k}}\;\text{A•m}^2\right)\times\left(0.55\hat{\mathbf{i}} + 0.60\hat{\mathbf{j}} - 0.65\hat{\mathbf{k}}\right)\text{T} = \boxed{\left(2.6\hat{\mathbf{i}} - 2.4\hat{\mathbf{j}}\right)\text{m•N}}$$

(*c*) We use Eq. 27-12 to find the potential energy of the coil.

$$U = -\vec{\boldsymbol{\mu}}\cdot\vec{\mathbf{B}} = -\left(-4.334\;\hat{\mathbf{k}}\;\text{A•m}^2\right)\left(0.55\hat{\mathbf{i}} + 0.60\hat{\mathbf{j}} - 0.65\hat{\mathbf{k}}\right)\text{T} = -\left(4.334\,\text{A•m}^2\right)(0.65\;\text{T})$$
$$= \boxed{-2.8\;\text{J}}$$

40. To find the total magnetic moment, we divide the rod into infinitesimal pieces of thickness *dy*. As the rod rotates on its axis the charge in each piece, $(Q/d)\,dy$, creates a current loop around the axis of rotation. The magnitude of the current is the charge times the frequency of rotation, $\omega/2\pi$. By integrating the infinitesimal magnetic moments from each piece, we find the total magnetic moment.

$$\vec{\boldsymbol{\mu}} = \int d\vec{\boldsymbol{\mu}} = \int \vec{\mathbf{A}}\,dI = \int_0^d (\pi y^2)\left(\frac{\omega}{2\pi}\frac{Q}{d}dy\right) = \frac{Q\omega}{2d}\int_0^d y^2 dy = \boxed{\frac{Q\omega d^2}{6}}.$$

41. From Section 27-5, we see that the torque is proportional to the current, so if the current drops by 12%, the output torque will also drop by 12%. Thus the final torque is 0.88 times the initial torque.

42. In Section 27-6, it is shown that the deflection of the galvanometer needle is proportional to the product of the current and the magnetic field. Thus if the magnetic field is decreased to 0.860 times its original value, the current must be increased by dividing the original value by 0.860 to obtain the same deflection.

$$(IB)_{\text{initial}} = (IB)_{\text{final}} \quad \rightarrow \quad I_{\text{final}} = \frac{I_{\text{initial}} B_{\text{initial}}}{B_{\text{final}}} = \frac{(63.0\,\mu\text{A})\,B_{\text{initial}}}{0.800 B_{\text{initial}}} = \boxed{78.8\,\mu\text{A}}$$

43. From the galvanometer discussion in Section 27-6, the amount of deflection is proportional to the ratio of the current and the spring constant: $\phi \propto \frac{I}{k}$. Thus if the spring constant decreases by 15%, the current can decrease by 15% to produce the same deflection. The new current will be 85% of the original current.

$$I_{\text{final}} = 0.85 I_{\text{initial}} = 0.85(46\,\mu\text{A}) = \boxed{39\,\mu\text{A}}$$

44. Use Eq. 27-13.

$$\frac{q}{m} = \frac{E}{B^2 r} = \frac{(260\,\text{V/m})}{(0.46\,\text{T})^2 (0.0080\,\text{m})} = \boxed{1.5\times10^5\,\text{C/kg}}$$

45. The force from the electric field must be equal to the weight.

$$|qE| = (ne)\left(\frac{V}{d}\right) = mg \quad \rightarrow \quad n = \frac{mgd}{eV} = \frac{(3.3\times10^{-15}\,\text{kg})(9.80\,\text{m/s}^2)(0.010\,\text{m})}{(1.60\times10^{-19})(340\,\text{V})} = 5.94 \approx \boxed{6\text{ electrons}}$$

46. (*a*) Eq. 27-14 shows that the Hall emf is proportional to the magnetic field perpendicular to the conductor's surface. We can use this proportionality to determine the unknown resistance. Since the new magnetic field is oriented 90° to the surface, the full magnetic field will be used to create the Hall potential.

$$\frac{\mathscr{E}_H'}{\mathscr{E}_H} = \frac{B_\perp'}{B_\perp} \rightarrow B_\perp' = \frac{\mathscr{E}_H'}{\mathscr{E}_H} B_\perp = \frac{63\,\text{mV}}{12\,\text{mV}}(0.10\,\text{T}) = \boxed{0.53\,\text{T}}$$

(*b*) When the field is oriented at 60° to the surface, the magnetic field, $B\sin 60°$, is used to create the Hall potential.

$$B_\perp' \sin 60° = \frac{\mathscr{E}_H'}{\mathscr{E}_H} B_\perp \rightarrow B_\perp' = \frac{63\text{ mV}}{12\text{ mV}} \frac{(0.10\,\text{T})}{\sin 60°} = \boxed{0.61\,\text{T}}$$

47. (*a*) We use Eq. 27-14 for the Hall Potential and Eq. 25-13 to write the current in terms of the drift velocity.

$$K_H = \frac{\mathscr{E}_H}{IB} = \frac{v_d B d}{\left[en(td)v_d\right]B} = \boxed{\frac{1}{ent}}$$

(*b*) We set the magnetic sensitivities equal and solve for the metal thickness.

$$\frac{1}{en_s t_s} = \frac{1}{en_m t_m} \rightarrow t_m = \frac{n_s}{n_m} t_s = \frac{3\times10^{22}\,\text{m}^{-3}}{1\times10^{29}\text{ m}^{-3}}(0.15\times10^{-3}\,\text{m}) = \boxed{5\times10^{-11}\text{ m}}$$

This is less than one sixth the size of a typical metal atom.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) Use the magnetic sensitivity to calculate the Hall potential.

$$\mathscr{E}_H = K_H IB = \frac{IB}{ent} = \frac{(100\text{ mA})(0.1\text{T})}{(1.6\times10^{-19}\text{C})(3\times10^{22}\text{m}^{-3})(0.15\times10^{-3}\text{m})} = 14\text{ mV} \approx \boxed{10\text{ mV}}$$

48. (*a*) We find the Hall field by dividing the Hall emf by the width of the metal.

$$E_H = \frac{\mathscr{E}_H}{d} = \frac{6.5\ \mu\text{V}}{0.03\text{ m}} = 2.167\times10^{-4}\text{ V/m} \approx \boxed{2.2\times10^{-4}\text{ V/m}}$$

(*b*) Since the forces from the electric and magnetic fields are balanced, we can use Eq. 27-14 to calculate the drift velocity.

$$v_d = \frac{E_H}{B} = \frac{2.167\times10^{-4}\text{ V/m}}{0.80\text{T}} = 2.709\times10^{-4}\text{ m/s} \approx \boxed{2.7\times10^{-4}\text{ m/s}}$$

(*c*) We now find the density using Eq. 25-13.

$$n = \frac{I}{eAv_d} = \frac{42\text{ A}}{(1.6\times10^{-19}\text{C})(6.80\times10^{-4}\text{m})(0.03\text{m})(2.709\times10^{-4}\text{m/s})}$$
$$= \boxed{4.7\times10^{28}\text{ electrons/m}^3}$$

49. We find the magnetic field using Eq. 27-14, with the drift velocity given by Eq. 25-13. To determine the electron density we divide the density of sodium by its atomic weight. This gives the number of moles of sodium per cubic meter. Multiplying the result by Avogadro's number gives the number of sodium atoms per cubic meter. Since there is one free electron per atom, this is also the density of free electrons.

$$B = \frac{\mathscr{E}_H}{v_d d} = \frac{\mathscr{E}_H}{\left(\frac{I}{ne(td)}\right)d} = \frac{\mathscr{E}_H net}{I} = \frac{\mathscr{E}_H et}{I}\left(\frac{\rho N_A}{m_A}\right)$$
$$= \frac{(1.86\times10^{-6}\text{V})(1.60\times10^{-19}\text{C})(1.30\times10^{-3}\text{m})}{12.0\text{ A}} \frac{(0.971)(1000\text{ kg/m}^3)(6.022\times10^{23}\text{e/mole})}{0.02299\text{ kg/mole}}$$
$$= \boxed{0.820\text{T}}$$

50. (*a*) The sign of the ions will not change the magnitude of the Hall emf, but will determine the polarity of the emf.

(*b*) The flow velocity corresponds to the drift velocity in Eq. 27-14.

$$\mathscr{E}_H = vBd \quad \rightarrow \quad \rightarrow \quad v = \frac{\mathscr{E}_H}{Bd} = \frac{(0.13\times10^{-3}\text{V})}{(0.070\text{T})(0.0033\text{m})} = \boxed{0.56\text{ m/s}}$$

51. The magnetic force on the ions causes them to move in a circular path, so the magnetic force is a centripetal force. This results in the ion mass being proportional to the path's radius of curvature.

$$qvB = mv^2/r \quad \rightarrow \quad m = qBr/v \quad \rightarrow \quad m/r = qB/v = \text{constant} = 76\ \text{u}/22.8\text{ cm}$$

$$\frac{m_{21.0}}{21.0\text{ cm}} = \frac{76\text{ u}}{22.8\text{ cm}} \quad \rightarrow \quad m_{21.0} = 70\text{ u} \qquad \frac{m_{21.6}}{21.6\text{ cm}} = \frac{76\text{ u}}{22.8\text{ cm}} \quad \rightarrow \quad m_{21.6} = 72\text{ u}$$

$$\frac{m_{21.9}}{21.9\text{ cm}} = \frac{76\text{ u}}{22.8\text{ cm}} \quad \rightarrow \quad m_{21.9} = 73\text{ u} \qquad \frac{m_{22.2}}{22.2\text{ cm}} = \frac{76\text{ u}}{22.8\text{ cm}} \quad \rightarrow \quad m_{22.2} = 74\text{ u}$$

The other masses are 70 u, 72 u, 73 u, and 74 u.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

52. The velocity of the ions is found using energy conservation. The electrical potential energy of the ions becomes kinetic energy as they are accelerated. Then, since the ions move perpendicularly to the magnetic field, the magnetic force will be a maximum. That force will cause the ions to move in a circular path.

$$qvB = \frac{mv^2}{R} \quad \rightarrow \quad v = \frac{qBR}{m} \qquad qV = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m\left(\frac{qBR}{m}\right)^2 = \frac{q^2B^2R^2}{2m} \quad \rightarrow \quad m = \frac{qR^2B^2}{2V}$$

53. The location of each line on the film is twice the radius of curvature of the ion. The radius of curvature can be found from the expression given in Section 27-9.

$$m = \frac{qBB'r}{E} \quad \rightarrow \; r = \frac{mE}{qBB'} \quad \rightarrow \quad 2r = \frac{2mE}{qBB'}$$

$$2r_{12} = \frac{2(12)\left(1.67\times10^{-27}\,\text{kg}\right)\left(2.48\times10^{4}\,\text{V/m}\right)}{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.58\,\text{T}\right)^2} = 1.8467\times10^{-2}\,\text{m}$$

$$2r_{13} = 2.0006\times10^{-2}\,\text{m} \qquad 2r_{14} = 2.1545\times10^{-2}\,\text{m}$$

The distances between the lines are

$$2r_{13} - 2r_{12} = 2.0006\times10^{-2}\,\text{m} - 1.8467\times10^{-2}\,\text{m} = 1.539\times10^{-3}\,\text{m} \approx \boxed{1.5\times10^{-3}\,\text{m}}$$

$$2r_{14} - 2r_{13} = 2.1545\times10^{-2}\,\text{m} - 2.0006\times10^{-2}\,\text{m} = 1.539\times10^{-3}\,\text{m} \approx \boxed{1.5\times10^{-3}\,\text{m}}$$

If the ions are doubly charged, the value of q in the denominator of the expression would double, and so the actual distances on the film would be halved. Thus the distances between the lines would also be halved.

$$2r_{13} - 2r_{12} = 1.0003\times10^{-2}\,\text{m} - 9.2335\times10^{-3}\,\text{m} = 7.695\times10^{-4}\,\text{m} \approx \boxed{7.7\times10^{-4}\,\text{m}}$$

$$2r_{14} - 2r_{13} = 1.07725\times10^{-2}\,\text{m} - 1.0003\times10^{-2}\,\text{m} = 7.695\times10^{-4}\,\text{m} \approx \boxed{7.7\times10^{-4}\,\text{m}}$$

54. The particles in the mass spectrometer follow a semicircular path as shown in Fig. 27-33. A particle has a displacement of $2r$ from the point of entering the semicircular region to where it strikes the film. So if the separation of the two molecules on the film is 0.65 mm, the difference in radii of the two molecules is 0.325 mm. The mass to radius ratio is the same for the two molecules.

$$qvB = mv^2/r \quad \rightarrow \quad m = qBr/v \quad \rightarrow \quad m/r = \text{constant}$$

$$\left(\frac{m}{r}\right)_{\text{CO}} = \left(\frac{m}{r}\right)_{\text{N}_2} \quad \rightarrow \quad \frac{28.0106\,\text{u}}{r} = \frac{28.0134\,\text{u}}{r + 3.25\times10^{-4}\,\text{m}} \quad \rightarrow \quad r = 3.251\,\text{m} \approx \boxed{3.3\,\text{m}}$$

55. Since the particle is undeflected in the crossed fields, its speed is given by Eq. 27-8. Without the electric field, the particle will travel in a circle due to the magnetic force. Using the centripetal acceleration, we can calculate the mass of the particle. Also, the charge must be an integer multiple of the fundamental charge.

$$qvB = \frac{mv^2}{r} \quad \rightarrow$$

$$m = \frac{qBr}{v} = \frac{qBr}{(E/B)} = \frac{neB^2r}{E} = \frac{n\left(1.60\times10^{-19}\,\text{C}\right)\left(0.034\,\text{T}\right)^2\left(0.027\,\text{m}\right)}{1.5\times10^{3}\,\text{V/m}} = n\left(3.3\times10^{-27}\,\text{kg}\right) \approx n\left(2.0\,\text{u}\right)$$

The particle has an atomic mass of a multiple of 2.0 u. The simplest two cases are that it could be a hydrogen-2 nucleus (called a deuteron), or a helium-4 nucleus (called an alpha particle): $\boxed{{}^{2}_{1}\text{H},\,{}^{4}_{2}\text{He}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

56. The radius and magnetic field values can be used to find the speed of the protons. The electric field is then found from the fact that the magnetic force must be the same magnitude as the electric force for the protons to have straight paths.

$$qvB = mv^2/r \;\rightarrow\; v = qBr/m \qquad F_E = F_B \;\rightarrow\; qE = qvB \;\rightarrow$$

$$E = vB = qB^2r/m = \frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.625\,\text{T}\right)^2\left(5.10\times10^{-2}\,\text{m}\right)}{1.67\times10^{-27}\,\text{kg}} = \boxed{1.91\times10^6\ \text{V/m}}$$

The direction of the electric field must be perpendicular to both the velocity and the magnetic field, and must be in the opposite direction to the magnetic force on the protons.

57. The magnetic force produces centripetal acceleration.

$$qvB = mv^2/r \;\rightarrow\; mv = p = qBr \;\rightarrow\; B = \frac{p}{qr} = \frac{3.8\times10^{-16}\,\text{kg•m/s}}{\left(1.60\times10^{-19}\,\text{C}\right)\left(1.0\times10^3\,\text{m}\right)} = \boxed{2.4\,\text{T}}$$

The magnetic field must point upward to cause an inward-pointing (centripetal) force that steers the protons clockwise.

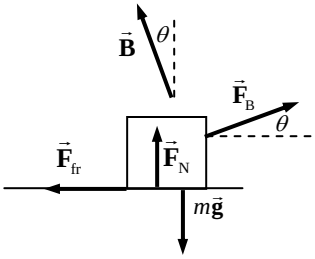
58. The kinetic energy is used to determine the speed of the particles, and then the speed can be used to determine the radius of the circular path, since the magnetic force is causing centripetal acceleration.

$$K = \tfrac{1}{2}mv^2 \;\rightarrow\; v = \sqrt{\frac{2K}{m}} \qquad qvB = \frac{mv^2}{r} \;\rightarrow\; r = \frac{mv}{qB} = \frac{m\sqrt{\dfrac{2K}{m}}}{qB} = \frac{\sqrt{2mK}}{qB}$$

$$\frac{r_p}{r_e} = \frac{\dfrac{\sqrt{2m_pK}}{qB}}{\dfrac{\sqrt{2m_eK}}{qB}} = \sqrt{\frac{m_p}{m_e}} = \sqrt{\frac{1.67\times10^{-27}\,\text{kg}}{9.11\times10^{-31}\,\text{kg}}} = \boxed{42.8}$$

59. (*a*) There will be one force on the rod, due to the magnetic force on the charge carriers in the rod. That force is of magnitude $F_B = IdB$, and by Newton's second law is equal to the mass of the rod times its acceleration. That force is constant, so the acceleration will be constant, and constant acceleration kinematics can be used.

$$F_{net} = F_B = IdB = ma \;\rightarrow\; a = \frac{IdB}{m} = \frac{v - v_0}{t} = \frac{v}{t} \;\rightarrow\; v = \boxed{\frac{IdB}{m}t}$$



(*b*) Now the net force is the vector sum of the magnetic force and the force of kinetic friction.

$$F_{net} = F_B - F_{fr} = IdB - \mu_k F_N = IdB - \mu_k mg = ma \;\rightarrow$$

$$a = \frac{IdB}{m} - \mu_k g = \frac{v - v_0}{t} = \frac{v}{t} \;\rightarrow\; v = \boxed{\left(\frac{IdB}{m} - \mu_k g\right)t}$$

(*c*) Using the right hand rule, we find that the force on the rod is to the east, and the rod moves east.

60. Assume that the magnetic field makes an angle θ with respect to the vertical. The rod will begin to slide when the horizontal magnetic force $(IB\ell\cos\theta)$ is equal to the maximum static friction $(\mu_s F_N)$. Find the normal force by setting the sum of the vertical forces equal to zero. See the free body diagram.

$$F_B\sin\theta + F_N - mg = 0 \;\rightarrow\; F_N = mg - F_B\sin\theta = mg - I\ell B\sin\theta$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$IB\ell\cos\theta = \mu_s F_N = \mu_s\left(mg - I\ell B\sin\theta\right) \;\rightarrow\; B = \frac{\mu_s mg}{I\ell\left(\mu_s\sin\theta+\cos\theta\right)}$$

We find the angle for the minimum magnetic field by setting the derivative of the magnetic field with respect to the angle equal to zero and solving for the angle.

$$\frac{dB}{d\theta} = 0 = \frac{-\mu_s mg\left(\mu_s\cos\theta-\sin\theta\right)}{I\ell\left(\mu_s\sin\theta+\cos\theta\right)^2} \;\rightarrow \theta = \tan^{-1}\mu_s = \tan^{-1}0.5 = 26.6°$$

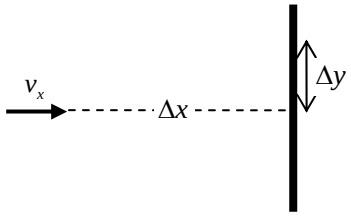
$$B = \frac{\mu_s mg}{I\ell\left(\mu_s\sin\theta+\cos\theta\right)} = \frac{0.5(0.40\,\text{kg})\left(9.80\,\text{m/s}^2\right)}{(36\,\text{A})(0.22\,\text{m})(0.5\sin 26.6°+\cos 26.6°)} = 0.22\,\text{T}$$

The minimum magnetic field that will cause the rod to move is 0.22 T at 27° from the vertical.

61. The magnetic force must be equal in magnitude to the weight of the electron.

$$mg = qvB \;\rightarrow\; v = \frac{mg}{qB} = \frac{\left(9.11\times10^{-31}\,\text{kg}\right)\left(9.80\,\text{m/s}^2\right)}{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.50\times10^{-4}\,\text{T}\right)} = \boxed{1.1\times10^{-6}\,\text{m/s}}$$

The magnetic force must point upwards, and so by the right hand rule and the negative charge of the electron, the electron must be moving west .



62. The airplane is a charge moving in a magnetic field. Since it is flying perpendicular to the magnetic field, Eq. 27-5b applies.

$$F_{\max} = qvB = \left(1850\times10^{-6}\,\text{C}\right)\left(120\,\text{m/s}\right)\left(5.0\times10^{-5}\,\text{T}\right) = \boxed{1.1\times10^{-5}\,\text{N}}$$

63. The maximum torque is found using Eq. 27-9 with $\sin\theta = 1$. Set the current equal to the voltage divided by resistance and the area as the square of the side length.

$$\tau = NIAB = N\left(\frac{V}{R}\right)\ell^2 B = 20\left(\frac{9.0\,\text{V}}{24\,\Omega}\right)(0.050\,\text{m})^2\,(0.020\,\text{T}) = \boxed{3.8\times10^{-4}\,\text{m•N}}$$

64. The speed of the electrons is found by assuming the energy supplied by the accelerating voltage becomes kinetic energy of the electrons. We assume that those electrons are initially directed horizontally, and that the television set is oriented so that the electron velocity is perpendicular to the Earth's magnetic field, resulting in the largest possible force. Finally, we assume that the magnetic force on the electrons is small enough that the electron velocity is essentially perpendicular to the Earth's field for the entire trajectory. This results in a constant acceleration for the electrons.

(*a*) Acceleration:

$$U_{\text{initial}} = K_{\text{final}} \;\rightarrow\; eV = \tfrac{1}{2}mv_x^2 \;\rightarrow\; v_x = \sqrt{\frac{2eV}{m}}$$

Deflection:

$$\text{time in field: } \Delta x_{\text{field}} = v_x t_{\text{field}} \;\rightarrow\; t_{\text{field}} = \frac{\Delta x_{\text{field}}}{v_x}$$

$$F_y = qv_x B_{\text{Earth}} = ma_y \;\rightarrow\; a_y = \frac{qv_x B_{\text{Earth}}}{m} = \frac{e\sqrt{\frac{2eV}{m}}B_{\text{Earth}}}{m} = \sqrt{\frac{2e^3V}{m^3}}B_{\text{Earth}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\Delta y = \tfrac{1}{2} a_y t^2 = \tfrac{1}{2}\sqrt{\frac{2e^3V}{m^3}}B_{\text{Earth}}\left(\frac{\Delta x_{\text{field}}}{v_x}\right)^2 = \tfrac{1}{2}\sqrt{\frac{2e^3V}{m^3}}B_{\text{Earth}}(\Delta x)^2\frac{m}{2eV}$$

$$= \sqrt{\frac{e}{8mV}}B_{\text{Earth}}(\Delta x)^2 = \sqrt{\frac{1.60\times10^{-19}\,\text{C}}{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(2.0\times10^{3}\,\text{V}\right)}}\left(5.0\times10^{-5}\,\text{T}\right)\left(0.18\,\text{m}\right)^2$$

$$= 5.37\times10^{-3}\,\text{m} \approx \boxed{5.4\,\text{mm}}$$

(*b*) $$\Delta y = \sqrt{\frac{e}{8mV}}B_{\text{Earth}}(\Delta x)^2 = \sqrt{\frac{1.60\times10^{-19}\,\text{C}}{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(28{,}000\,\text{V}\right)}}\left(5.0\times10^{-5}\,\text{T}\right)\left(0.18\,\text{m}\right)^2$$

$$= \boxed{1.4\times10^{-3}\,\text{m}}$$

Note that the deflection is significantly smaller than the horizontal distance traveled, and so the assumptions made above are verified.

65. From Fig. 27-22 we see that when the angle θ is positive, the torque is negative. The magnitude of the torque is given by Eq. 27-9. For small angles we use the approximation $\sin\theta \approx \theta$. Using Eq. 10-14, we can write the torque in terms of the angular acceleration, showing that it is a harmonic oscillator.

$$\tau = -NIAB\sin\theta \approx -IabB\theta = I_M\alpha \quad\rightarrow\quad \alpha = -\left(\frac{IabB}{I_M}\right)\theta = -\omega^2\theta$$

We obtain the period of motion from the angular frequency, using $T = 2\pi/\omega$. First we determine the moment of inertia of the loop, as two wires rotating about their centers of mass and two wires rotating about an axis parallel to their lengths.

$$I_M = 2\left[\frac{1}{12}\left(\frac{b}{2a+2b}m\right)b^2\right] + 2\left(\frac{a}{2a+2b}m\right)\left(\frac{b}{2}\right)^2 = \frac{(3a+b)mb^2}{12(a+b)}$$

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{I_M}{NIabB}} = 2\pi\sqrt{\frac{mb^2(3a+b)}{12(a+b)NIabB}} = \boxed{\pi\sqrt{\frac{mb(3a+b)}{3(a+b)NIaB}}}$$

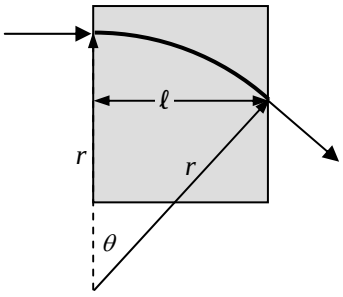
66. (*a*) The frequency of the voltage must match the frequency of circular motion of the particles, so that the electric field is synchronized with the circular motion. The radius of each circular orbit is given in Example 27-7 as $r = \dfrac{mv}{qB}$. For an object moving in circular motion, the period is given by $T = \dfrac{2\pi r}{v}$, and the frequency is the reciprocal of the period.

$$T = \frac{2\pi r}{v} \quad\rightarrow\quad f = \frac{v}{2\pi r} = \frac{v}{2\pi\dfrac{mv}{qB}} = \boxed{\frac{Bq}{2\pi m}}$$

In particular we note that this frequency is independent of the radius, and so the same frequency can be used throughout the acceleration.

(*b*) For a small gap, the electric field across the gap will be approximately constant and uniform as the particles cross the gap. If the motion and the voltage are synchronized so that the maximum voltage occurs when the particles are at the gap, the particles receive an energy increase of

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

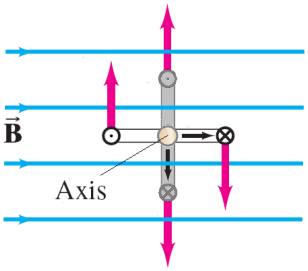


$K = qV_0$ as they pass each gap. The energy gain from one revolution will include the passing of 2 gaps, so the total kinetic energy increase is $\boxed{2qV_0}$.

(*c*) The maximum kinetic energy will occur at the outside of the cyclotron.

$$K_{\max} = \tfrac{1}{2}mv_{\max}^2 = \tfrac{1}{2}m\left(\frac{r_{\max}qB}{m}\right)^2 = \tfrac{1}{2}\frac{r_{\max}^2 q^2 B^2}{m} = \tfrac{1}{2}\frac{(0.50\,\text{m})^2(1.60\times10^{-19}\,\text{C})^2(0.60\,\text{T})^2}{1.67\times10^{-27}\,\text{kg}}$$

$$= 6.898\times10^{-13}\,\text{J}\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right)\left(\frac{1\,\text{MeV}}{10^6\,\text{eV}}\right) = \boxed{4.3\,\text{MeV}}$$



67. The protons will follow a circular path as they move through the region of magnetic field, with a radius of curvature given in Example 27-7 as $r = \dfrac{mv}{qB}$. Fast-moving protons will have a radius of curvature that is too large and so they will exit above the second tube. Likewise, slow-moving protons will have a radius of curvature that is too small and so they will exit below the second tube. Since the exit velocity is perpendicular to the radius line from the center of curvature, the bending angle can be calculated.

$$\sin\theta = \frac{\ell}{r} \rightarrow$$

$$\theta = \sin^{-1}\frac{\ell}{r} = \sin^{-1}\frac{\ell qB}{mv} = \sin^{-1}\frac{(5.0\times10^{-2}\,\text{m})(1.60\times10^{-19}\,\text{C})(0.38\,\text{T})}{(1.67\times10^{-27}\,\text{kg})(0.85\times10^{7}\,\text{m/s})} = \sin^{-1}0.214 = \boxed{12°}$$

68. (*a*) The force on each of the vertical wires in the loop is perpendicular to the magnetic field and is given by Eq. 27-1, with $\theta = 90°$. When the face of the loop is parallel to the magnetic field, the forces point radially away from the axis. This provides a tension in the two horizontal sides. When the face of the loop is perpendicular to the magnetic field, the force on opposite vertical wires creates a shear force in the horizontal wires. From Table 12-2, we see that the tensile and shear strengths of aluminum are the same, so either can be used to determine the minimum strength. We set tensile strength multiplied by the cross-sectional area of the two wires equal the tensile strength multiplied by the safety factor and solve for the wire diameter.

$$\frac{F}{A}\pi\left(\frac{d}{2}\right)^2 = 10(I\ell B) \rightarrow d = 2\sqrt{\frac{10(I\ell B)}{\pi(F/A)}} = 2\sqrt{\frac{10(15.0\text{ A})(0.200\text{ m})(1.35\text{ T})}{\pi(200\times10^6\text{ N/m}^2)}}$$

$$= 5.0777\times10^{-4}\text{ m} \approx \boxed{0.508\text{ mm}}$$

(*b*) The resistance is found from the resistivity using Eq. 25-3.

$$R = \rho\frac{\ell}{A} = (2.65\times10^{-8}\,\Omega\cdot\text{m})\frac{4(0.200\,\text{m})}{\pi\left(\frac{5.0777\times10^{-4}}{2}\,\text{m}\right)^2} = \boxed{0.105\,\Omega}$$

69. The accelerating force on the bar is due to the magnetic force on the current. If the current is constant, the magnetic force will be constant, and so constant acceleration kinematics can be used.

$$v^2 = v_0^2 + 2a\Delta x \quad \rightarrow \quad a = \frac{v^2 - 0}{2\Delta x} = \frac{v^2}{2\Delta x}$$

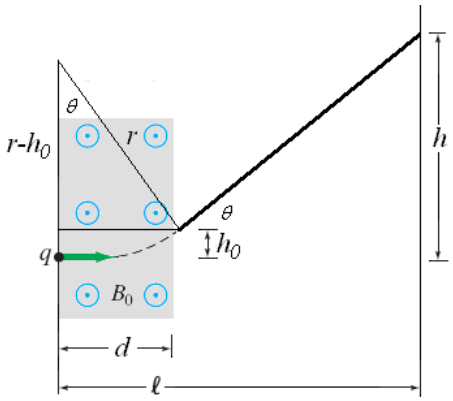
$$F_{\text{net}} = ma = IdB \quad \rightarrow \quad I = \frac{ma}{dB} = \frac{m\left(\frac{v^2}{2\Delta x}\right)}{dB} = \frac{mv^2}{2\Delta x dB} = \frac{(1.5\times10^{-3}\,\text{kg})(25\,\text{m/s})^2}{2(1.0\,\text{m})(0.24\,\text{m})(1.8\,\text{T})} = \boxed{1.1\,\text{A}}$$

Using the right hand rule, for the force on the bar to be in the direction of the acceleration shown in Fig. 27-53, the magnetic field must be down .

70. (*a*) For the beam of electrons to be undeflected, the magnitude of the magnetic force must equal the magnitude of the electric force. We assume that the magnetic field will be perpendicular to the velocity of the electrons so that the maximum magnetic force is obtained.

$$F_B = F_E \quad \rightarrow \quad qvB = qE \quad \rightarrow \quad B = \frac{E}{v} = \frac{8400\,\text{V/m}}{4.8\times10^6\,\text{m/s}} = 1.75\times10^{-3}\,\text{T} \approx \boxed{1.8\times10^{-3}\,\text{T}}$$

(*b*) Since the electric field is pointing up, the electric force is down. Thus the magnetic force must be up. Using the right hand rule with the negative electrons, the magnetic field must be out of the plane of the plane formed by the electron velocity and the electric field.



(*c*) If the electric field is turned off, then the magnetic field will cause a centripetal force, moving the electrons in a circular path. The frequency is the reciprocal of the period of the motion.

$$qvB = \frac{mv^2}{r} \quad \rightarrow \quad v = \frac{qBr}{m}$$

$$f = \frac{1}{T} = \frac{v}{2\pi r} = \frac{\frac{qBr}{m}}{2\pi r} = \frac{qB}{2\pi m} = \frac{qE}{2\pi mv} = \frac{(1.60\times10^{-19}\,\text{C})(8400\,\text{V/m})}{2\pi(9.11\times10^{-31}\,\text{kg})(4.8\times10^6\,\text{m/s})} = \boxed{4.9\times10^7\,\text{Hz}}$$

71. We find the speed of the electron using conservation of energy. The accelerating potential energy becomes the kinetic energy of the electron.

$$eV = \tfrac{1}{2}mv^2 \quad \rightarrow \quad v = \sqrt{\frac{2eV}{m}}$$

Upon entering the magnetic field the electron is traveling horizontally. The magnetic field will cause the path of the electron to rotate an angle θ from the horizontal. While in the field, the electron will travel a horizontal distance d and a vertical distance h_0. Using the Pythagorean theorem, and trigonometric relations, we can write three equations which relate the unknown parameters, r, h_0, and θ.

$$\tan\theta = \frac{h - h_0}{\ell - d} \qquad \sin\theta = \frac{d}{r} \qquad r^2 = d^2 + (r - h_0)^2 \rightarrow h_0 = r - \sqrt{r^2 - d^2}$$

These three equations can be directly solved, for the radius of curvature. However, doing so requires solving a 3rd order polynomial. Instead, we can guess at a value for h_0, such as 1.0 cm. Then we use the tangent equation to calculate an approximate value for θ. Then insert the approximate value into the sine equation to solve for r. Finally, inserting the value of r into the third equation we solve for h_0. We then use the new value of h_0 as our guess and reiterated the process a couple of times until the value of h_0 does not significantly change.

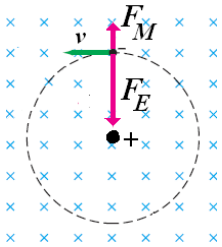
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\theta = \tan^{-1}\left(\frac{11\text{cm}-1.0\text{cm}}{22\text{cm}-3.5\text{cm}}\right) = 28.39° \rightarrow r = \frac{3.5\text{cm}}{\sin 28.39°} = 7.36\text{cm}$$

$$\rightarrow h_0 = 7.36\text{cm} - \sqrt{(7.36\text{cm})^2 - (3.5\text{cm})^2} = 0.885\text{cm}$$

$$\theta = \tan^{-1}\left(\frac{11\text{ cm}-0.885\text{ cm}}{22\text{ cm}-3.5\text{ cm}}\right) = 28.67° \rightarrow r = \frac{3.5\text{ cm}}{\sin 28.67°} = 7.30\text{ cm}$$

$$\rightarrow h_0 = 7.30\text{ cm} - \sqrt{(7.30\text{ cm})^2 - (3.5\text{ cm})^2} = 0.894\text{ cm}$$



$$\theta = \tan^{-1}\left(\frac{11\text{ cm}-0.894\text{ cm}}{22\text{ cm}-3.5\text{ cm}}\right) = 28.65° \rightarrow r = \frac{3.5\text{ cm}}{\sin 28.67°} = 7.30\text{cm}$$

$$\rightarrow h_0 = 7.30\text{cm} - \sqrt{(7.30\text{cm})^2 - (3.5\text{cm})^2} = 0.894\text{cm}$$

The magnetic field can be determined from the trajectory's radius, as done in Example 27-7.

$$r = \frac{mv}{eB} \quad \rightarrow \quad B = \frac{mv}{er} = \frac{m}{er}\sqrt{\frac{2eV}{m}} = \sqrt{\frac{2mV}{er^2}} = \sqrt{\frac{2\left(9.11\times10^{-31}\text{kg}\right)\left(25\times10^{3}\text{V}\right)}{\left(1.60\times10^{-19}\text{ C}\right)\left(0.0730\text{m}\right)^2}} = \boxed{7.3\text{mT}}$$

72. (*a*) As the electron orbits the nucleus in the absence of the magnetic field, its centripetal acceleration is caused solely by the electrical attraction between the electron and the nucleus. Writing the velocity of the electron as the circumference of its orbit times its frequency, enables us to obtain an equation for the frequency of the electron's orbit.

$$\frac{ke^2}{r^2} = m\frac{v^2}{r} = m\frac{\left(2\pi r f_0\right)^2}{r} \rightarrow f_0^2 = \frac{ke^2}{4\pi^2 mr^3}$$

When the magnetic field is added, the magnetic force adds or subtracts from the centripetal acceleration (depending on the direction of the field) resulting in the change in frequency.

$$\frac{ke^2}{r^2} \pm q\left(2\pi r f\right)B = m\frac{\left(2\pi r f\right)^2}{r} \rightarrow f^2 \mp \frac{qB}{2\pi m} f - f_0^2 = 0$$

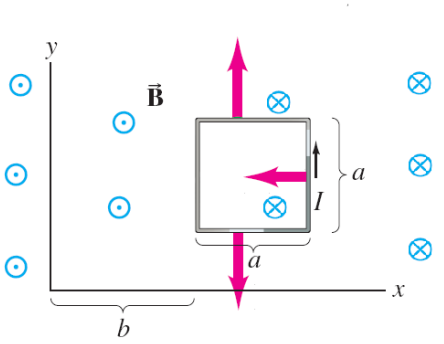
We can solve for the frequency shift by setting $f = f_0 + \Delta f$, and only keeping the lowest order terms, since $\Delta f \ll f_0$.

$$\left(f_0 + \Delta f\right)^2 \mp \frac{qB}{2\pi m}\left(f_0 + \Delta f\right) - f_0^2 = 0$$

$$\cancel{f_0^2} + 2f_0\Delta f + \cancel{\Delta f^2} \mp \frac{qB}{2\pi m} f_0 \mp \cancel{\frac{qB}{2\pi m}\Delta f} - \cancel{f_0^2} = 0 \quad \rightarrow \quad \boxed{\Delta f = \pm\frac{qB}{4\pi m}}$$

(*b*) The "±" indicates whether the magnetic force adds to or subtracts from the centripetal acceleration. If the magnetic force adds to the centripetal acceleration, the frequency increases. If the magnetic force is opposite in direction to the acceleration, the frequency decreases.

73. The speed of the proton can be calculated based on the radius of curvature of the (almost) circular motion. From that the kinetic energy can be calculated.



$$qvB = \frac{mv^2}{r} \quad \rightarrow \quad v = \frac{qBr}{m} \qquad K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m\left(\frac{qBr}{m}\right)^2 = \frac{q^2B^2r^2}{2m}$$

$$\Delta K = \frac{q^2B^2}{2m}\left(r_2^2 - r_1^2\right) = \frac{\left(1.60\times10^{-19}\text{C}\right)^2\left(0.018\text{T}\right)^2}{2\left(1.67\times10^{-27}\text{kg}\right)}\left[\left(8.5\times10^{-3}\text{m}\right)^2 - \left(10.0\times10^{-3}\text{m}\right)^2\right]$$

$$= \boxed{-6.9\times10^{-20}\text{J}} \text{ or } -0.43\text{eV}$$

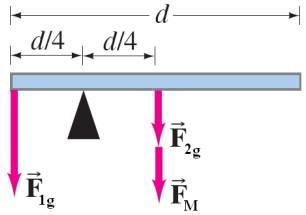
74. The forces on each of the two horizontal sides of the loop have the same magnitude, but opposite directions, so these forces sum to zero. The left side of the loop is located at $x = b$, where the magnetic field is zero, and therefore the force is zero. The net force is the force acting on the right side of the loop. By the right hand rule, with the current directed toward the top of the page and the magnetic field into the page, the force will point in the negative x direction with magnitude given by Eq. 27-2.

$$\vec{\mathbf{F}} = I\ell B\left(-\hat{\mathbf{i}}\right) = IaB_0\left(1-\frac{b+a}{b}\right)\hat{\mathbf{i}} = \boxed{-\frac{Ia^2B_0}{b}\hat{\mathbf{i}}}$$

75. We assume that the horizontal component of the Earth's magnetic field is pointing due north. The Earth's magnetic field also has the dip angle of 22°. The angle between the magnetic field and the eastward current is 90°. Use Eq. 27-1 to calculate the magnitude of the force.

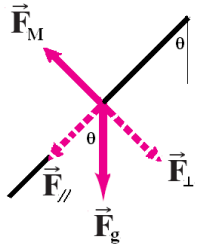


$$F = I\ell B\sin\theta = (330\,\text{A})(5.0\,\text{m})\left(5.0\times10^{-5}\,\text{T}\right)\sin 90^\circ$$

$$= \boxed{0.083\,\text{N}}$$

Using the right hand rule with the eastward current and the Earth's magnetic field, the force on the wire is northerly and 68° above the horizontal.

76. Since the magnetic and gravitational force along the entire rod is uniform, we consider the two forces acting at the center of mass of the rod. To be balanced, the net torque about the fulcrum must be zero. Using the usual sign convention for torques and Eq. 10-10a, we solve for the magnetic force on the rod.



$$\sum\tau = 0 = Mg\left(\tfrac{1}{4}d\right) - mg\left(\tfrac{1}{4}d\right) - F_M\left(\tfrac{1}{4}d\right) \;\rightarrow\; F_M = (M-m)g$$

We solve for the current using Eq. 27-2.

$$I = \frac{F}{\ell B} = \frac{(M-m)g}{dB} = \frac{(8.0m-m)g}{dB} = \boxed{\frac{7.0mg}{dB}}$$

The right hand rule indicates that the current must flow toward the left since the magnetic field is into the page and the magnetic force is downward.

77. (*a*) For the rod to be in equilibrium, the gravitational torque and the magnetic torque must be equal and opposite. Since the rod is uniform, the two torques can be considered to act at the same location (the center of mass). Therefore, components of the two forces perpendicular to the rod must be equal and opposite. Since the gravitational force points downward, its perpendicular component will point down and to the right. The magnetic force is perpendicular to the rod and must point towards the left to oppose the perpendicular component of the gravitational force. By the right hand rule, with a magnetic field pointing out of the page, the current must flow downward from the pivot to produce this force.

(*b*) We set the magnitude of the magnetic force, using Eq. 27-2, equal to the magnitude of the perpendicular component of the gravitational force, $F_\perp = mg\sin\theta$, and solve for the magnetic field.

$$I\ell B = mg\sin\theta \;\rightarrow\; B = \frac{mg\sin\theta}{I\ell} = \frac{(0.150\,\text{kg})(9.80\,\text{m/s}^2)\sin 13^\circ}{(12\,\text{A})(1.0\,\text{m})} = \boxed{0.028\,\text{T}}$$

(*c*) The largest magnetic field that could be measured is when $\theta = 90^\circ$.

$$B_{\text{max}} = \frac{mg\sin 90^\circ}{I\ell} = \frac{(0.150\,\text{kg})(9.80\,\text{m/s}^2)\sin 90^\circ}{(12\,\text{A})(1.0\,\text{m})} = \boxed{0.12\,\text{T}}$$

CHAPTER 28: Sources of Magnetic Field

Responses to Questions

1. Alternating currents will have little effect on the compass needle, due to the rapid change of the direction of the current and of the magnetic field surrounding it. Direct currents will deflect a compass needle. The deflection depends on the magnitude and direction of the current and the distance from the current to the compass. The effect on the compass decreases with increasing distance from the wire.

2. The magnetic field due to a long straight current is proportional to the current strength. The electric field due to a long straight line of electric charge at rest is proportional to the charge per unit length. Both fields are inversely proportional to the distance from the wire or line of charge. The magnetic field lines form concentric circles around the wire; the electric field lines are directed radially outward if the line of charge is positive and radially inward if the line of charge is negative.

3. The magnetic forces exerted on one wire by the other try to align the wires. The net force on either wire is zero, but the net torque is not zero.

4. Yes. Assume the upper wire is fixed in position. Since the currents in the wires are in the same direction, the wires will attract each other. The lower wire will be held in equilibrium if this force of attraction (upward) is equal in magnitude to the weight of the wire (downward).

5. (*a*) The current in the lower wire is opposite in direction to the current in the upper wire.
   (*b*) The upper wire can be held in equilibrium due to the balance between the magnetic force from the lower wire and the gravitational force. The equilibrium will be stable for small vertical displacements, but not for horizontal displacements.

6. (*a*) Let $I_2 = I_1$. $\oint \vec{\mathbf{B}} \cdot d\vec{\ell} = \mu_0 I_{\text{encl}} = \mu_0 \left(I_1 + I_2 \right) = 2\mu_0 I_1$
   (*b*) Let $I_2 = -I_1$. $\oint \vec{\mathbf{B}} \cdot d\vec{\ell} = \mu_0 I_{\text{encl}} = \mu_0 \left(I_1 + I_2 \right) = 0$

7. Inside the cavity $\vec{\mathbf{B}} = 0$ since the geometry is cylindrical and no current is enclosed.

8. Construct a closed path similar to that shown in part (*a*) of the figure, such that sides *ab* and *cd* are perpendicular to the field lines and sides *bc* and *da* lie along the field lines. Unlike part (*a*), the path will not form a rectangle; the sides *ab* and *cd* will flare outward so that side *bc* is longer than side *da*. Since the field is stronger in the region of *da* than it is in the region of *bc*, but *da* is shorter than *bc*, the contributions to the integral in Ampère's law may cancel. Thus, $\mu_0 I_{\text{encl}} = \oint \vec{\mathbf{B}} \cdot d\vec{\ell} = 0$ is possible and the field is consistent with Ampère's law. The lines could not curve upward instead of downward, because then *bc* would be shorter than *da* and it would not be possible for the contributions to sum to zero.

9. The equation for the magnetic field strength inside a solenoid is given by $B = \mu_0 nI$.
   (*a*) The magnetic field strength is not affected if the diameter of the loops doubles.
   (*b*) If the spacing between the loops doubles, the number of loops per unit length decreases by a factor of 2, and the magnetic field strength then also decreases by a factor of 2.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

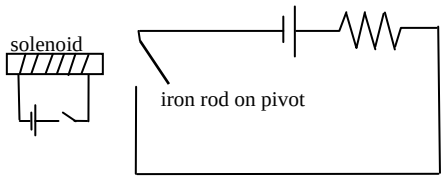
(*c*) If the solenoid's length is doubled along with the doubling of the total number of loops, then the number of loops per unit length remains the same, and the magnetic field strength is not affected.

10. The Biot-Savart law states that the net field at a point in space is the vector sum of the field contributions due to each infinitesimal current element. As shown in Example 28-12, the magnetic field along the axis of a current loop is parallel to the axis because the perpendicular field contributions cancel. However, for points off the axis, the perpendicular contributions will not cancel. The net field for a point off the axis will be dominated by the current elements closest to it. For example, in Figure 28-21, the field lines inside the loop but below the axis curve downward, because these points in space are closer to the lower segment of the loop (where the current goes into the page) than they are to the upper segment (where the current comes out of the page).

11. No. The magnetic field varies in strength and direction for points in the plane of the loop. The magnetic field is strongest at the center of the loop.

12. The lead-in wires to electrical devices have currents running in opposite directions. The magnetic fields due to these currents are therefore also opposite in direction. If the wires are twisted together, then the distance from a point outside the wires to each of the individual wires is about the same, and the field contributions from the two wires will cancel. If the wires were not twisted and were separate from each other, then a point outside the wires would be a different distance from one of the wires than from the other, and there would be a net field due to the currents in the wires.

13. The Biot-Savart law and Coulomb's law are both inverse-square in the radius and both contain a proportionality constant. Coulomb's law describes a central force; the Biot-Savart law involves a cross product of vectors and so cannot describe a central force.



14. (*a*) The force between two identical electric charges is given by Coulomb's law: $F = \dfrac{kq^2}{r^2}$.

Magnetic pole strength of a bar magnet could be defined using an analogous expression for the magnetic force between the poles of two identical magnets: $F = \dfrac{\mu m^2}{4\pi r^2}$. Then, magnetic pole strength, *m*, would be given by $m = \sqrt{\dfrac{4\pi F r^2}{\mu}}$. To determine *m*, place two identical magnets with their poles facing each other a distance *r* apart and measure the force between them.

(*b*) The magnetic pole strength of a current loop could be defined the same way by using two identical current loops instead of two bar magnets.

15. Determine the magnetic field of the Earth at one of the magnetic poles (north or south), and use Equation 28-7b to calculate the magnetic moment. In this equation, *x* will be (approximately) the radius of the Earth.

16. To design a relay, place an iron rod inside a solenoid, with the solenoid oriented such that one end of it is facing a second iron rod on a pivot. The second iron rod functions as a switch for the large-current circuit and is normally held open by a spring. When current flows through the solenoid, the iron rod inside it becomes magnetized and attracts the second iron rod, closing the switch and allowing current to flow.

17. (*a*) The source of the kinetic energy is the attractive force produced by the magnetic field from the magnet acting on the magnetic moments of the atoms in the iron.
(*b*) When the block strikes the magnet, some of the kinetic energy from the block is converted into kinetic energy in the iron atoms in the magnet, randomizing their magnetic moments and decreasing the overall field produced by the magnet. Some of the kinetic energy of the block as a whole is also converted into the kinetic energy of the individual atoms in the block, resulting in an increase in thermal energy.

18. No, a magnet with a steady field will only attract objects made of ferromagnetic materials. Aluminum is not ferromagnetic, so the magnetic field of the magnet will not cause the aluminum to become a temporary magnet and therefore there will be no attractive force. Iron is ferromagnetic, so in the presence of a magnet, the domains in a piece of iron will align such that it will be attracted to the magnet.

19. An unmagnetized nail has randomly oriented domains and will not generate an external magnetic field. Therefore, it will not attract an unmagnitized paper clip, which also has randomly oriented domains. When one end of the nail is in contact with a magnet, some of the domains in the nail align, producing an external magnetic field and turning the nail into a magnet. The magnetic nail will cause some of the domains in the paper clip to align, and it will be attracted to the nail.

20. Yes, an iron rod can attract a magnet and a magnet can attract an iron rod. Consider Newton's third law. If object A attracts object B then object B attracts object A.

21. Domains in ferromagnetic materials in molten form were aligned by the Earth's magnetic field and then fixed in place as the material cooled.

22. Yes. When a magnet is brought near an unmagnetized piece of iron, the magnet's field causes a temporary alignment of the domains of the iron. If the magnet's north pole is brought near the iron, then the domains align such that the temporary south pole of the iron is facing the magnet, and if the magnet's south pole is closest to the iron, then the alignment will be the opposite. In either case, the magnet and the iron will attract each other.

23. The two rods that have ends that repel each other will be the magnets. The unmagnetized rod will be attracted to both ends of the magnetized rods.

24. No. If they were both magnets, then they would repel one another when they were placed with like poles facing each other. However, if one is a magnet and the other isn't, they will attract each other no matter which ends are placed together. The magnet will cause an alignment of the domains of the non-magnet, causing an attraction.

25. (*a*) The magnetization curve for a paramagnetic substance is a straight line with slope slightly greater than 1. It passes through the origin; there is no hysteresis.
(*b*) The magnetization curve for a diamagnetic substance is a straight line with slope slightly less than 1. It passes through the origin; there is no hysteresis.
The magnetization curve for a ferromagnetic substance is a hysteresis curve (see Figure 28-29).

26. (*a*) Yes. Diamagnetism is present in all materials but in materials that are also paramagnetic or ferromagnetic, its effects will not be noticeable.
(*b*) No. Paramagnetic materials are nonferromagnetic materials with a relative permeability greater than one.
(*c*) No. Ferromagnetic materials are those that can be magnetized by alignment of their domains.

Solutions to Problems

1. We assume the jumper cable is a long straight wire, and use Eq. 28-1.

$$B_{\text{cable}} = \frac{\mu_0 I}{2\pi r} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(65\text{A})}{2\pi(0.035\,\text{m})} = 3.714\times10^{-4}\,\text{T} \approx \boxed{3.7\times10^{-4}\,\text{T}}$$

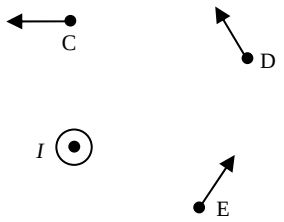
Compare this to the Earth's field of $0.5\times10^{-4}\,\text{T}$.

$$B_{\text{cable}}/B_{\text{Earth}} = \frac{3.714\times10^{-4}\,\text{T}}{5.0\times10^{-5}\,\text{T}} = 7.43\text{, so } \boxed{\text{the field of the cable is over 7 times that of the Earth.}}$$

2. We assume that the wire is long and straight, and use Eq. 28-1.

$$B_{\text{wire}} = \frac{\mu_0 I}{2\pi r} \rightarrow I = \frac{2\pi r B_{\text{wire}}}{\mu_0} = \frac{2\pi(0.15\,\text{m})\left(0.50\times10^{-4}\,\text{T}\right)}{4\pi\times10^{-7}\ \text{T•m/A}} = 37.5\,\text{A} \approx \boxed{38\,\text{A}}$$

3. Since the currents are parallel, the force on each wire will be attractive, toward the other wire. Use Eq. 28-2 to calculate the magnitude of the force.



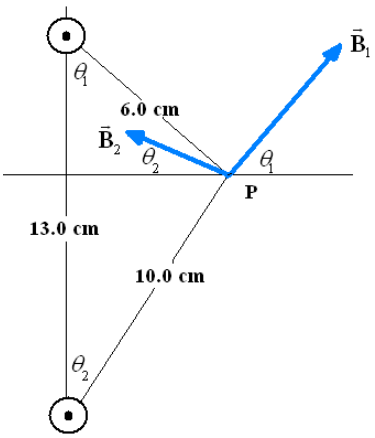
$$F_2 = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d}\ell_2 = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)}{2\pi}\frac{(35\,\text{A})^2}{(0.040\,\text{m})}(25\,\text{m}) = \boxed{0.15\,\text{N, attractive}}$$

4. Since the force is attractive, the currents must be in the same direction, so the current in the second wire must also be upward. Use Eq. 28-2 to calculate the magnitude of the second current.

$$F_2 = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d}\ell_2 \rightarrow$$

$$I_2 = \frac{2\pi}{\mu_0}\frac{F_2}{\ell_2}\frac{d}{I_1} = \frac{2\pi}{4\pi\times10^{-7}\ \text{T•m/A}}\left(7.8\times10^{-4}\ \text{N/m}\right)\frac{0.070\,\text{m}}{28\,\text{A}} = 9.75\,\text{A} \approx \boxed{9.8\,\text{A upward}}$$

5. To find the direction, draw a radius line from the wire to the field point. Then at the field point, draw a perpendicular to the radius line, directed so that the perpendicular line would be part of a counterclockwise circle.



6. For the experiment to be accurate to $\pm 2.0\%$, the magnetic field due to the current in the cable must be less than or equal to 2.0% of the Earth's magnetic field. Use Eq. 28-1 to calculate the magnetic field due to the current in the cable.

$$B_{\text{cable}} = \frac{\mu_0 I}{2\pi r} \le 0.020 B_{\text{Earth}} \rightarrow I \le \frac{2\pi r\left(0.020 B_{\text{Earth}}\right)}{\mu_0} = \frac{2\pi(1.00\,\text{m})(0.020)\left(0.5\times10^{-4}\,\text{T}\right)}{4\pi\times10^{-7}\ \text{T•m/A}} = 5.0\,\text{A}$$

Thus the maximum allowable current is $\boxed{5.0\,\text{A}}$.

7. Since the magnetic field from a current carrying wire circles the wire, the individual field at point P from each wire is perpendicular to the radial line from that wire to point P. We define $\vec{\mathbf{B}}_1$ as the field from the top wire, and $\vec{\mathbf{B}}_2$ as the field from the bottom wire. We use Eq. 28-1 to calculate the magnitude of each individual field.

$$B_1 = \frac{\mu_0 I}{2\pi r_1} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(35\,\text{A})}{2\pi(0.060\,\text{m})} = 1.17\times10^{-4}\,\text{T}$$

$$B_2 = \frac{\mu_0 I}{2\pi r_2} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(35\,\text{A})}{2\pi(0.100\,\text{m})} = 7.00\times10^{-5}\,\text{T}$$

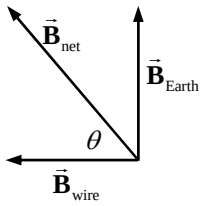
We use the law of cosines to determine the angle that the radial line from each wire to point P makes with the vertical. Since the field is perpendicular to the radial line, this is the same angle that the magnetic fields make with the horizontal.

$$\theta_1 = \cos^{-1}\left(\frac{(0.060\ \text{m})^2 + (0.130\ \text{m})^2 - (0.100\ \text{m})^2}{2(0.060\ \text{m})(0.130\ \text{m})}\right) = 47.7°$$

$$\theta_2 = \cos^{-1}\left(\frac{(0.100\ \text{m})^2 + (0.130\ \text{m})^2 - (0.060\ \text{m})^2}{2(0.100\ \text{m})(0.130\ \text{m})}\right) = 26.3°$$

Using the magnitudes and angles of each magnetic field we calculate the horizontal and vertical components, add the vectors, and calculate the resultant magnetic field and angle.

$$B_{\text{net}\,x} = B_1\cos(\theta_1) - B_2\cos\theta_2 = \left(1.174\times10^{-4}\,\text{T}\right)\cos 47.7° - \left(7.00\times10^{-5}\,\text{T}\right)\cos 26.3° = 1.626\times10^{-5}\,\text{T}$$

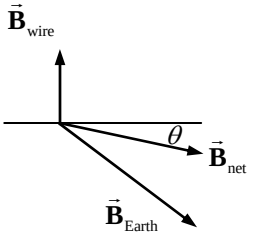


$$B_{\text{net}\,y} = B_1\sin(\theta_1) + B_2\sin\theta_1 = \left(1.17\times10^{-4}\,\text{T}\right)\sin 47.7° + \left(7.00\times10^{-5}\,\text{T}\right)\sin 26.3° = 1.18\times10^{-4}\,\text{T}$$

$$B = \sqrt{B_{net,x}^2 + B_{net,y}^2} = \sqrt{\left(1.626\times10^{-5}\ \text{T}\right)^2 + \left(1.18\times10^{-4}\ \text{T}\right)^2} = 1.19\times10^{-4}\ \text{T}$$

$$\theta = \tan^{-1}\frac{B_{net,y}}{B_{net,y}} = \tan^{-1}\frac{1.18\times10^{-4}\ \text{T}}{1.626\times10^{-5}\ \text{T}} = 82.2°$$

$$\vec{\mathbf{B}} = 1.19\times10^{-4}\ \text{T}\ @\ 82.2° \approx \boxed{1.2\times10^{-4}\,\text{T}\ @\ 82°}$$



8. At the location of the compass, the magnetic field caused by the wire will point to the west, and the Earth's magnetic field points due North. The compass needle will point in the direction of the NET magnetic field.

$$B_{\text{wire}} = \frac{\mu_0 I}{2\pi r} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(43\,\text{A})}{2\pi(0.18\,\text{m})} = 4.78\times10^{-5}\,\text{T}$$

$$\theta = \tan^{-1}\frac{B_{\text{Earth}}}{B_{\text{wire}}} = \tan^{-1}\frac{4.5\times10^{-5}\,\text{T}}{4.78\times10^{-5}\,\text{T}} = \boxed{43°\text{N of W}}$$

9. The magnetic field due to the long horizontal wire points straight up at the point in question, and its magnitude is given by Eq. 28-1. The two fields are oriented as shown in the diagram. The net field is the vector sum of the two fields.

$$B_{\text{wire}} = \frac{\mu_0 I}{2\pi r} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(24.0\,\text{A})}{2\pi(0.200\,\text{m})} = 2.40\times10^{-5}\,\text{T}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$B_{\text{Earth}} = 5.0\times10^{-5}\text{T}$$

$$B_{\text{net }x} = B_{\text{Earth}}\cos 44^\circ = 3.60\times10^{-5}\text{T} \qquad B_{\text{net }y} = B_{\text{wire}} - B_{\text{Earth}}\sin 44^\circ = -1.07\times10^{-5}\text{T}$$

$$B_{\text{net}} = \sqrt{B_{\text{net }x}^2 + B_{\text{net }y}^2} = \sqrt{\left(3.60\times10^{-5}\text{T}\right)^2 + \left(-1.07\times10^{-5}\text{T}\right)^2} = \boxed{3.8\times10^{-5}\text{T}}$$

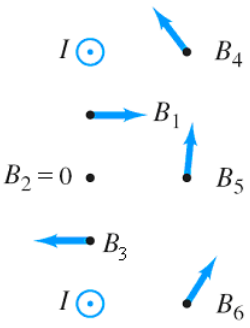
$$\theta = \tan^{-1}\frac{B_{\text{net }y}}{B_{\text{net }x}} = \tan^{-1}\frac{-1.07\times10^{-5}\text{T}}{3.60\times10^{-5}\text{T}} = \boxed{17^\circ \text{ below the horizontal}}$$

10. The stream of protons constitutes a current, whose magnitude is found by multiplying the proton rate times the charge of a proton. Then use Eq. 28-1 to calculate the magnetic field.

$$B_{\text{stream}} = \frac{\mu_0 I}{2\pi r} = \frac{\left(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}\right)\left(2.5\times10^{9}\ \text{protons/s}\right)\left(1.60\times10^{-19}\ \text{C/proton}\right)}{2\pi\left(2.0\,\text{m}\right)} = \boxed{4.0\times10^{-17}\text{T}}$$

11. (*a*) If the currents are in the same direction, the magnetic fields at the midpoint between the two currents will oppose each other, and so their magnitudes should be subtracted.

$$B_{\text{net}} = \frac{\mu_0 I_1}{2\pi r_1} - \frac{\mu_0 I_2}{2\pi r_2} = \frac{\left(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}\right)}{2\pi\left(0.010\,\text{m}\right)}\left(I - 25\,\text{A}\right) = \boxed{\left(2.0\times10^{-5}\ \text{T/A}\right)\left(I - 25\,\text{A}\right)}$$



(*b*) If the currents are in the opposite direction, the magnetic fields at the midpoint between the two currents will reinforce each other, and so their magnitudes should be added.

$$B_{\text{net}} = \frac{\mu_0 I_1}{2\pi r_1} + \frac{\mu_0 I_2}{2\pi r_2} = \frac{\left(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}\right)}{2\pi\left(0.010\,\text{m}\right)}\left(I + 25\,\text{A}\right) = \boxed{\left(2.0\times10^{-5}\ \text{T/A}\right)\left(I + 25\,\text{A}\right)}$$

12. Using the right-hand-rule we see that if the currents flow in the same direction, the magnetic fields will oppose each other between the wires, and therefore can equal zero at a given point. Set the sum of the magnetic fields from the two wires equal to zero at the point 2.2 cm from the first wire and use Eq. 28-1 to solve for the unknown current.

$$B_{net} = 0 = \frac{\mu_0 I_1}{2\pi r_1} - \frac{\mu_0 I_2}{2\pi r_2} \rightarrow I_2 = \left(\frac{r_2}{r_1}\right) I_1 = \left(\frac{6.0\,\text{cm} - 2.2\,\text{cm}}{2.2\,\text{cm}}\right)\left(2.0\,\text{A}\right) = \boxed{3.5\,\text{A}}$$

13. Use the right hand rule to determine the direction of the magnetic field from each wire. Remembering that the magnetic field is inversely proportional to the distance from the wire, qualitatively add the magnetic field vectors. The magnetic field at point #2 is zero.

14. The fields created by the two wires will oppose each other, so the net field is the difference of the magnitudes of the two fields. The positive direction for the fields is taken to be into the paper, and so the closer wire creates a field in the positive direction, and the farther wire creates a field in the negative direction. Let *d* be the separation distance of the wires.

$$B_{\text{net}} = \frac{\mu_0 I}{2\pi r_{\text{closer}}} - \frac{\mu_0 I}{2\pi r_{\text{farther}}} = \frac{\mu_0 I}{2\pi}\left(\frac{1}{r_{\text{closer}}} - \frac{1}{r_{\text{farther}}}\right) = \frac{\mu_0 I}{2\pi}\left(\frac{1}{r - \frac{1}{2}d} - \frac{1}{r + \frac{1}{2}d}\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \frac{\mu_0 I}{2\pi}\left(\frac{d}{\left(r-\frac{1}{2}d\right)\left(r+\frac{1}{2}d\right)}\right)$$

$$= \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(28.0\ \text{A})}{2\pi}\left(\frac{0.0028\ \text{m}}{(0.10\ \text{m}-0.0014\ \text{m})(0.10\ \text{m}+0.0014\ \text{m})}\right)$$

$$= 1.568\times10^{-6}\ \text{T} \approx \boxed{1.6\times10^{-6}\ \text{T}}$$

Compare this to the Earth's field of $0.5\times10^{-4}\ \text{T}$.

$$B_{\text{net}}/B_{\text{Earth}} = \frac{1.568\times10^{-6}\ \text{T}}{0.5\times10^{-4}\ \text{T}} = 0.031$$

The field of the wires is about 3% that of the Earth.

15. The center of the third wire is 5.6 mm from the left wire, and 2.8 mm from the right wire. The force on the near (right) wire will attract the near wire, since the currents are in the same direction. The force on the far (left) wire will repel the far wire, since the currents oppose each other. Use Eq. 28-2 to calculate the force per unit length.

$$F_{\text{near}} = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d_{\text{near}}}\ell_{\text{near}} \quad \rightarrow$$

$$\frac{F_{\text{near}}}{\ell_{\text{near}}} = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d_{\text{near}}} = \frac{4\pi\times10^{-7}\ \text{T•m/A}}{2\pi}\frac{(25.0\ \text{A})(28.0\ \text{A})}{2.8\times10^{-3}\ \text{m}} = \boxed{0.050\ \text{N/m, attractive}}$$

$$F_{\text{far}} = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d_{\text{far}}}\ell_{\text{far}} \quad \rightarrow$$

$$\frac{F_{\text{far}}}{\ell_{\text{far}}} = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d_{\text{far}}} = \frac{4\pi\times10^{-7}\ \text{T•m/A}}{2\pi}\frac{(25.0\ \text{A})(28.0\ \text{A})}{5.6\times10^{-3}\ \text{m}} = \boxed{0.025\ \text{N/m, repelling}}$$

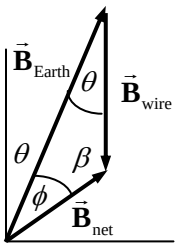
16. (*a*) We assume that the power line is long and straight, and use Eq. 28-1.

$$B_{\text{line}} = \frac{\mu_0 I}{2\pi r} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(95\ \text{A})}{2\pi(8.5\ \text{m})} = 2.235\times10^{-6}\ \text{T} \approx \boxed{2.2\times10^{-6}\ \text{T}}$$

The direction at the ground, from the right hand rule, is south. Compare this to the Earth's field of $0.5\times10^{-4}\ \text{T}$, which points approximately north.

$$B_{\text{line}}/B_{\text{Earth}} = \frac{2.235\times10^{-6}\ \text{T}}{0.5\times10^{-4}\ \text{T}} = 0.0447$$

The field of the cable is about 4% that of the Earth.



(*b*) We solve for the distance where $B_{\text{line}} = B_{\text{Earth}}$.

$$B_{\text{line}} = \frac{\mu_0 I}{2\pi r} = B_{\text{Earth}} \quad \rightarrow \quad r = \frac{\mu_0 I}{2\pi B_{\text{Earth}}} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(95\ \text{A})}{2\pi\left(0.5\times10^{-4}\ \text{T}\right)} = 0.38\ \text{m} \approx \boxed{0.4\ \text{m}}$$

So about 0.4 m below the wire, the net B-field would be 0, assuming the Earth's field points straight north at this location.

17. The Earth's magnetic field is present at both locations in the problem, and we assume it is the same at both locations. The field east of a vertical wire must be pointing either due north or due south. The compass shows the direction of the net magnetic field, and it changes from 28° E of N to 55° E of N when taken inside. That is a "southerly" change (rather than a "northerly" change), and so the field due to the wire must be pointing due south. See the diagram. For the angles, $\theta = 28°$, $\theta + \phi = 55°$, and $\beta + \theta + \phi = 180°$ and so $\phi = 27°$ and $\beta = 125°$. Use the law of sines to find the magnitude of $\vec{\mathbf{B}}_{\text{wire}}$, and then use Eq. 28-1 to find the magnitude of the current.

$$\frac{B_{\text{wire}}}{\sin\phi} = \frac{B_{\text{Earth}}}{\sin\beta} \rightarrow B_{\text{wire}} = B_{\text{Earth}}\frac{\sin\phi}{\sin\beta} = \frac{\mu_0}{2\pi}\frac{I}{r} \rightarrow$$

$$I = B_{\text{Earth}}\frac{\sin\phi}{\sin\beta}\frac{2\pi}{\mu_0}r = \left(5.0\times10^{-5}\,\text{T}\right)\frac{\sin 27^\circ}{\sin 125^\circ}\frac{2\pi}{4\pi\times10^{-7}\,\text{T}\bullet\text{m/A}}\left(0.120\,\text{m}\right) = \boxed{17\,\text{A}}$$

Since the field due to the wire is due south, the current in the wire must be down.

18. The magnetic field at the loop due to the long wire is into the page, and can be calculated by Eq. 28-1. The force on the segment of the loop closest to the wire is towards the wire, since the currents are in the same direction. The force on the segment of the loop farthest from the wire is away from the wire, since the currents are in the opposite direction.

Because the magnetic field varies with distance, it is more difficult to calculate the total force on the left and right segments of the loop. Using the right hand rule, the force on each small piece of the left segment of wire is to the left, and the force on each small piece of the right segment of wire is to the right. If left and right small pieces are chosen that are equidistant from the long wire, the net force on those two small pieces is zero. Thus the total force on the left and right segments of wire is zero, and so only the parallel segments need to be considered in the calculation. Use Eq. 28-2.

$$F_{\text{net}} = F_{\text{near}} - F_{\text{far}} = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d_{\text{near}}}\ell_{\text{near}} - \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d_{\text{far}}}\ell_{\text{far}} = \frac{\mu_0}{2\pi}I_1 I_2 \ell\left(\frac{1}{d_{\text{near}}} - \frac{1}{d_{\text{far}}}\right)$$

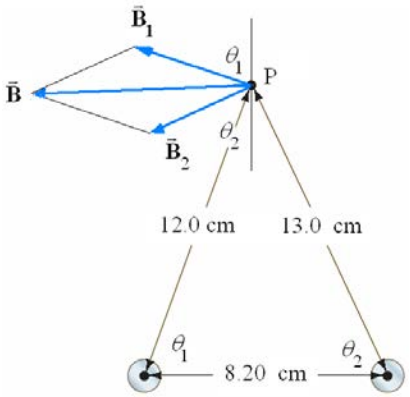
$$= \frac{4\pi\times10^{-7}\,\text{T}\bullet\text{m/A}}{2\pi}\left(3.5\,\text{A}\right)^2\left(0.100\,\text{m}\right)\left(\frac{1}{0.030\,\text{m}} - \frac{1}{0.080\,\text{m}}\right) = \boxed{5.1\times10^{-6}\,\text{N, towards wire}}$$

19. The left wire will cause a field on the *x* axis that points in the *y* direction, and the right wire will cause a field on the *x* axis that points in the negative *y* direction. The distance from the left wire to a point on the *x* axis is *x*, and the distance from the right wire is $d - x$.

$$\vec{\mathbf{B}}_{\text{net}} = \frac{\mu_0 I}{2\pi x}\hat{\mathbf{j}} - \frac{\mu_0 I}{2\pi(d-x)}\hat{\mathbf{j}} = \boxed{\frac{\mu_0 I}{2\pi}\left(\frac{1}{x} - \frac{1}{d-x}\right)\hat{\mathbf{j}}} = \boxed{\frac{\mu_0 I}{2\pi}\left(\frac{d-2x}{x(d-x)}\right)\hat{\mathbf{j}}}$$

20. The left wire will cause a field on the *x* axis that points in the negative *y* direction, and the right wire will also cause a field on the *x* axis that points in the negative *y* direction. The distance from the left wire to a point on the *x* axis is *x*, and the distance from the right wire is $d - x$.

$$\vec{\mathbf{B}}_{\text{net}} = -\frac{\mu_0(2I)}{2\pi x}\hat{\mathbf{j}} - \frac{\mu_0 I}{2\pi(d-x)}\hat{\mathbf{j}} = \boxed{-\frac{\mu_0 I}{2\pi}\left(\frac{2}{x} + \frac{1}{d-x}\right)\hat{\mathbf{j}}}$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21. The magnetic fields created by the individual currents will be at right angles to each other. The field due to the top wire will be to the right, and the field due to the bottom wire will be out of the page. Since they are at right angles, the net field is the hypotenuse of the two individual fields.

$$B_{\text{net}} = \sqrt{\left(\frac{\mu_0 I_{\text{top}}}{2\pi r_{\text{top}}}\right)^2 + \left(\frac{\mu_0 I_{\text{bottom}}}{2\pi r_{\text{bottom}}}\right)^2} = \frac{\mu_0}{2\pi r}\sqrt{I_{\text{top}}^2 + I_{\text{bottom}}^2} = \frac{4\pi\times10^{-7}\ \text{T•m/A}}{2\pi(0.100\,\text{m})}\sqrt{(20.0\,\text{A})^2 + (12.0\,\text{A})^2}$$

$$= \boxed{4.66\times10^{-5}\,\text{T}}$$

22. The net magnetic field is the vector sum of the magnetic fields produced by each current carrying wire. Since the individual magnetic fields encircle the wire producing it, the field is perpendicular to the radial line from the wire to point P. We let $\vec{\mathbf{B}}_1$ be the field from the left wire, and $\vec{\mathbf{B}}_2$ designate the field from the right wire. The magnitude of the magnetic field vectors is calculated from Eq. 28-1.

$$B_1 = \frac{\mu_0 I}{2\pi r_1} = \frac{(4\pi\times10^{-7}\ \text{T•m/A})(16.5\,\text{A})}{2\pi(0.12\,\text{m})} = 2.7500\times10^{-5}\,\text{T}$$

$$B_2 = \frac{\mu_0 I}{2\pi r_2} = \frac{(4\pi\times10^{-7}\ \text{T•m/A})(16.5\text{A})}{2\pi(0.13\text{m})} = 2.5385\times10^{-5}\,\text{T}$$

We use the law of cosines to determine the angle that the radial line from each wire to point P makes with the horizontal. Since the magnetic fields are perpendicular to the radial lines, these angles are the same as the angles the magnetic fields make with the vertical.

$$\theta_1 = \cos^{-1}\left(\frac{(0.12\ \text{m})^2 + (0.082\ \text{m})^2 - (0.13\ \text{m})^2}{2(0.12\ \text{m})(0.082\ \text{m})}\right) = 77.606°$$

$$\theta_2 = \cos^{-1}\left(\frac{(0.13\ \text{m})^2 + (0.082\ \text{m})^2 - (0.12\ \text{m})^2}{2(0.13\ \text{m})(0.082\ \text{m})}\right) = 64.364°$$

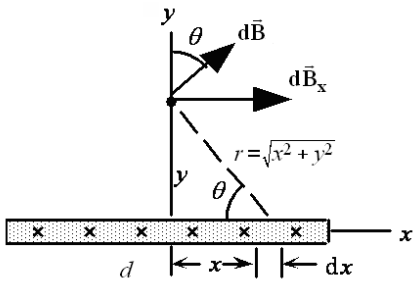
Using the magnitudes and angles of each magnetic field we calculate the horizontal and vertical components, add the vectors, and calculate the resultant magnetic field and angle.

$$B_{\text{net}\,x} = -B_1\sin(\theta_1) - B_2\sin\theta_2 = -(2.7500\times10^{-5}\text{T})\sin 77.606° - (2.5385\times10^{-5}\text{T})\sin 64.364°$$

$$= -49.75\times10^{-6}\,\text{T}$$

$$B_{\text{net}\,y} = B_1\cos(\theta_1) - B_2\cos\theta_1 = (2.7500\times10^{-5}\text{T})\cos 77.606° - (2.5385\times10^{-5}\text{T})\cos 64.364°$$

$$= -5.080\times10^{-6}\,\text{T}$$



$$B = \sqrt{B_{net,x}^2 + B_{net,y}^2} = \sqrt{(-49.75\times10^{-6}\ \text{T})^2 + (-5.080\times10^{-6}\ \text{T})^2} = 5.00\times10^{-5}\ \text{T}$$

$$\theta = \tan^{-1}\frac{B_{net,y}}{B_{net,y}} = \tan^{-1}\frac{-5.08\times10^{-6}\ \text{T}}{-49.75\times10^{-6}\ \text{T}} = 5.83°$$

$$\boxed{\vec{\mathbf{B}} = 5.00\times10^{-5}\ \text{T @ } 5.83°\text{ below the negative } x\text{-axis}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23. (*a*) The net magnetic field a point *y* above the center of the strip can be found by dividing the strip into infinitely thin wires and integrating the field contribution from each wire. Since the point is directly above the center of the strip, we see that the vertical contributions to the magnetic field from symmetric points on either side of the center cancel out. Therefore, we only need to integrate the horizontal component of the magnetic field. We use Eq. 28-1 for the magnitude of the magnetic field, with the current given by

$$dI = \frac{I}{d}dx.$$

$$B_x = \int \frac{\mu_0 \sin\theta}{2\pi r} dI = \frac{\mu_0 I}{2\pi d}\int_{-\frac{1}{2}d}^{\frac{1}{2}d} \frac{dx}{\sqrt{x^2+y^2}}\left(\frac{y}{\sqrt{x^2+y^2}}\right) = \frac{\mu_0 Iy}{2\pi d}\int_{-\frac{1}{2}d}^{\frac{1}{2}d} \frac{dx}{x^2+y^2}$$

$$= \frac{\mu_0 Iy}{2\pi d}\frac{1}{y}\tan^{-1}\frac{x}{y}\Big|_{-d/2}^{d/2} = \boxed{\frac{\mu_0 I}{\pi d}\tan^{-1}\left(\frac{d}{2y}\right)}$$

(*b*) In the limit of large *y*, $\tan^{-1} d/2y \approx d/2y$.

$$B_x = \frac{\mu_0 I}{\pi d}\tan^{-1}\left(\frac{d}{2y}\right) \approx \frac{\mu_0 I}{\pi d}\frac{d}{2y} = \boxed{\frac{\mu_0 I}{2\pi y}}$$

This is the same as the magnetic field for a long wire.

24. We break the current loop into the three branches of the triangle and add the forces from each of the three branches. The current in the parallel branch flows in the same direction as the long straight wire, so the force is attractive with magnitude given by Eq. 28-2.

$$F_1 = \frac{\mu_0 II'}{2\pi d}a$$

By symmetry the magnetic force for the other two segments will be equal. These two wires can be broken down into infinitesimal segments, each with horizontal length *dx*. The net force is found by integrating Eq. 28-2 over the side of the triangle. We set x=0 at the left end of the left leg. The distance of a line segment to the wire is then given by $r = d + \sqrt{3}x$. Since the current in these segments flows opposite the direction of the current in the long wire, the force will be repulsive.

$$F_2 = \int_0^{a/2} \frac{\mu_0 II'}{2\pi\left(d+\sqrt{3}x\right)}dx = \frac{\mu_0 II'}{2\pi\sqrt{3}}\ln\left(d+\sqrt{3}x\right)\Big|_0^{a/2} = \frac{\mu_0 II'}{2\pi\sqrt{3}}\ln\left(1+\frac{\sqrt{3}a}{2d}\right)$$

We calculate the net force by summing the forces from the three segments.

$$F = F_1 - 2F_2 = \frac{\mu_0 II'}{2\pi d}a - 2\frac{\mu_0 II'}{2\pi\sqrt{3}}\ln\left(1+\frac{\sqrt{3}a}{2d}\right) = \boxed{\frac{\mu_0 II'}{\pi}\left[\frac{a}{2d} - \frac{\sqrt{3}}{3}\ln\left(1+\frac{\sqrt{3}a}{2d}\right)\right]}$$

25. Use Eq. 28-4 for the field inside a solenoid.

$$B = \frac{\mu_0 IN}{\ell} \quad \rightarrow \quad I = \frac{B\ell}{\mu_0 N} = \frac{\left(0.385\times10^{-3}\,\text{T}\right)\left(0.400\,\text{m}\right)}{\left(4\pi\times10^{-7}\,\text{T}\bullet\text{m/A}\right)\left(765\right)} = \boxed{0.160\,\text{A}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

26. The field inside a solenoid is given by Eq. 28-4.

$$B = \frac{\mu_0 IN}{\ell} \quad \rightarrow \quad N = \frac{B\ell}{\mu_0 I} = \frac{(0.30\,\text{T})(0.32\,\text{m})}{(4\pi\times10^{-7}\,\text{T•m/A})(4.5\,\text{A})} = \boxed{1.7\times10^4\,\text{turns}}$$

27. (*a*) We use Eq. 28-1, with *r* equal to the radius of the wire.

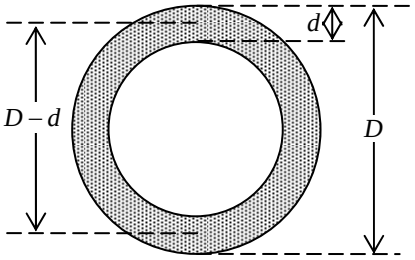
$$B = \frac{\mu_0 I}{2\pi r} = \frac{(4\pi\times10^{-7}\ \text{T•m/A})(33\ \text{A})}{2\pi(1.25\times10^{-3}\ \text{m})} = \boxed{5.3\ \text{mT}}$$

(*b*) We use the results of Example 28-6, for points inside the wire. Note that $r = (1.25 - 0.50)\,\text{mm} = 0.75\,\text{mm}$.

$$B = \frac{\mu_0 Ir}{2\pi R^2} = \frac{(4\pi\times10^{-7}\,\text{T•m/A})(33\,\text{A})(0.75\times10^{-3}\,\text{m})}{2\pi(1.25\times10^{-3}\,\text{m})^2} = \boxed{3.2\,\text{mT}}$$

(*c*) We use Eq. 28-1, with *r* equal to the distance from the center of the wire.

$$B = \frac{\mu_0 I}{2\pi r} = \frac{(4\pi\times10^{-7}\ \text{T•m/A})(33\ \text{A})}{2\pi(1.25\times10^{-3}\ \text{m} + 2.5\times10^{-3}\ \text{m})} = \boxed{1.8\ \text{mT}}$$



28. We use the results of Example 28-10 to find the maximum and minimum fields.

$$B_{\min} = \frac{\mu_0 NI}{2\pi r_{\max}} = \frac{(4\pi\times10^{-7}\ \text{T•m/A})(687)(25.0\ \text{A})}{2\pi(0.270\ \text{m})} = 12.7\ \text{mT}$$

$$B_{\max} = \frac{\mu_0 NI}{2\pi r_{\min}} = \frac{(4\pi\times10^{-7}\ \text{T•m/A})(687)(25.0\ \text{A})}{2\pi(0.250\ \text{m})} = 13.7\ \text{mT}$$

$$\boxed{12.7\ \text{mT} < B < 13.7\ \text{mT}}$$

29. (*a*) The copper wire is being wound about an average diameter that is approximately equal to the outside diameter of the solenoid minus the diameter of the wire, or $D - d$. See the (not to scale) end-view diagram. The length of each wrapping is $\pi(D - d)$. We divide the length of the wire L by the length of a single winding to determine the number of loops. The length of the solenoid is the number of loops multiplied by the outer diameter of the wire, *d*.

$$\ell = d\frac{L}{\pi(D-d)} = (2.00\times10^{-3}\,\text{m})\frac{20.0\,\text{m}}{\pi\left[2.50\times10^{-2}\,\text{m} - (2.00\times10^{-3}\,\text{m})\right]} = \boxed{0.554\,\text{m}}$$

(*b*) The field inside the solenoid is found using Eq. 28-4. Since the coils are wound closely together, the number of turns per unit length is equal to the reciprocal of the wire diameter.

$$n = \frac{\#\ \text{turns}}{\ell} = \frac{\frac{L}{\pi(D-d)}}{\ell} = \frac{\ell/d}{\ell} = \frac{1}{d}$$

$$B = \mu_0 nI = \frac{\mu_0 I}{d} = \frac{(4\pi\times10^{-7}\,\text{T•m/A})(16.7\,\text{A})}{2.00\times10^{-3}\,\text{m}} = \boxed{10.5\,\text{mT}}$$

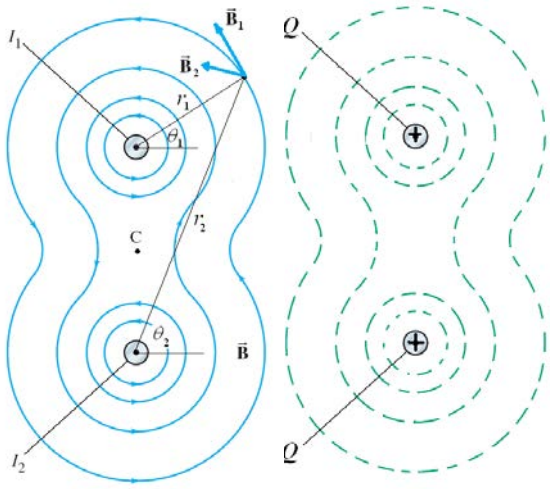
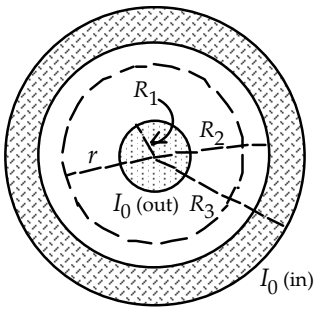
30. (*a*) The magnitude of the magnetic field from each wire is found using Eq. 28-1. The direction of the magnetic field is perpendicular to the radial vector from the current to the point of interest. Since the currents are both coming out of the page, the magnetic fields will point counterclockwise from the radial line. The total magnetic field is the vector sum of the individual fields.



$$\vec{\mathbf{B}} = \vec{\mathbf{B}}_1 + \vec{\mathbf{B}}_2 = \frac{\mu_0 I}{2\pi r_1}\left(-\sin\theta_1\hat{\mathbf{i}} + \cos\theta_1\hat{\mathbf{j}}\right) + \frac{\mu_0 I}{2\pi r_2}\left(-\sin\theta_2\hat{\mathbf{i}} + \cos\theta_2\hat{\mathbf{j}}\right)$$

$$= \frac{\mu_0 I}{2\pi}\left[\left(-\frac{\sin\theta_1}{r_1} - \frac{\sin\theta_1}{r_2}\right)\hat{\mathbf{i}} + \left(\frac{\cos\theta_1}{r_1} + \frac{\cos\theta_2}{r_2}\right)\hat{\mathbf{j}}\right]$$



This equation for the magnetic field shows that the *x*-component of the magnetic field is symmetric and the *y*-component is anti-symmetric about $\theta = 90°$.

(*b*) See sketch.

(*c*) The two diagrams are similar in shape, as both form loops around the central axes. However, the magnetic field lines form a vector field, showing the direction, not necessarily the magnitude of the magnetic field. The equipotential lines are from a scalar field showing the points of constant magnitude. The equipotential lines do not have an associated direction.

31. Because of the cylindrical symmetry, the magnetic fields will be circular. In each case, we can determine the magnetic field using Ampere's law with concentric loops. The current densities in the wires are given by the total current divided by the cross-sectional area.

$$J_{\text{inner}} = \frac{I_0}{\pi R_1^2} \qquad J_{\text{outer}} = -\frac{I_0}{\pi\left(R_3^2 - R_2^2\right)}$$

(*a*) Inside the inner wire the enclosed current is determined by the current density of the inner wire.

$$\oint \vec{\mathbf{B}}\cdot d\vec{s} = \mu_0 I_{\text{encl}} = \mu_0\left(J_{\text{inner}}\pi R^2\right)$$

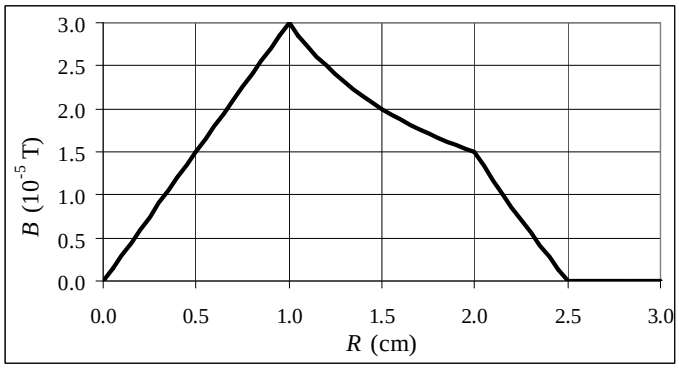
$$B\left(2\pi R\right) = \mu_0\frac{I_0\pi R^2}{\pi R_1^2} \rightarrow \boxed{B = \frac{\mu_0 I_0 R}{2\pi R_1^2}}$$

(*b*) Between the wires the current enclosed is the current on the inner wire.

$$\oint \vec{\mathbf{B}}\cdot d\vec{s} = \mu_0 I_{\text{encl}} \;\rightarrow\; B\left(2\pi R\right) = \mu_0 I_0 \;\rightarrow\; \boxed{B = \frac{\mu_0 I_0}{2\pi R}}$$

(*c*) Inside the outer wire the current enclosed is the current from the inner wire and a portion of the current from the outer wire.

$$\oint \vec{\mathbf{B}}\cdot d\vec{s} = \mu_0 I_{\text{encl}} = \mu_0\left[I_0 + J_{\text{outer}}\pi\left(R^2 - R_2^2\right)\right]$$



$$B\left(2\pi r\right) = \mu_0\left[I_0 - I_0\frac{\pi\left(R^2 - R_2^2\right)}{\pi\left(R_3^2 - R_2^2\right)}\right] \rightarrow \boxed{B = \frac{\mu_0 I_0}{2\pi R}\frac{\left(R_3^2 - R^2\right)}{\left(R_3^2 - R_2^2\right)}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*d*) Outside the outer wire the net current enclosed is zero.

$$\oint \vec{\mathbf{B}} \cdot d\vec{s} = \mu_0 I_{\text{encl}} = 0 \;\rightarrow\; B(2\pi R) = 0 \;\rightarrow\; \boxed{B = 0}$$

(*e*) See the adjacent graph. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH28.XLS," on tab "Problem 28.31e."

32. We first find the constants C_1 and C_2 by integrating the currents over each cylinder and setting the integral equal to the total current.

$$I_0 = \int_0^{R_1} C_1 R 2\pi R dR = 2\pi C_1 \int_0^{R_1} R^2 dR = \frac{2}{3}\pi R_1^3 C_1 \;\rightarrow\; C_1 = \frac{3I_0}{2\pi R_1^3}$$

$$-I_0 = 2\pi C_2 \int_{R_2}^{R_3} R^2 dR = \frac{2}{3}\pi\left(R_3^3 - R_2^3\right) C_2 \;\rightarrow\; C_2 = \frac{-3I_0}{2\pi\left(R_3^3 - R_2^3\right)}$$

(*a*) Inside the inner wire the enclosed current is determined by integrating the current density inside the radius R.

$$\oint \vec{\mathbf{B}} \cdot d\vec{s} = \mu_0 I_{\text{encl}} = \mu_0 \int_0^R \left(C_1 R'\right) 2\pi R' dR' = \frac{2}{3}\mu_0 \pi C_1 R^3 = \frac{2}{3}\mu_0 \pi \left(\frac{3I_0}{2\pi R_1^3}\right) R^3$$

$$B(2\pi R) = \mu_0 \frac{I_0 \pi R^3}{\pi R_1^3} \rightarrow \boxed{B = \frac{\mu_0 I_0 R^2}{2\pi R_1^3}}$$

(*b*) Between the wires the current enclosed is the current on the inner wire.

$$\oint \vec{\mathbf{B}} \cdot d\vec{s} = \mu_0 I_{\text{encl}} \;\rightarrow\; B(2\pi R) = \mu_0 I_0 \;\rightarrow\; \boxed{B = \frac{\mu_0 I_0}{2\pi R}}$$

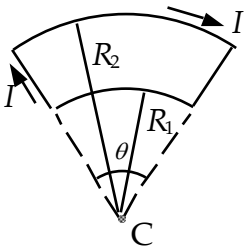
(*c*) Inside the outer wire the current enclosed is the current from the inner wire and a portion of the current from the outer wire.

$$\oint \vec{\mathbf{B}} \cdot d\vec{s} = \mu_0 I_{\text{encl}} = \mu_0 \left[I_0 + \int_{R_2}^{R} (C_2 R) 2\pi R dR \right] = \mu_0 \left[I_0 + \int_{R_2}^{R} (C_2 R) 2\pi R dR \right]$$

$$= \mu_0 I_0 \left[1 - \frac{2}{3}\pi C_2 \left(R^3 - R_2^3\right) \right] = \mu_0 \left[I_0 - \frac{\left(R^3 - R_2^3\right)}{\left(R_3^3 - R_2^3\right)} \right]$$

$$B(2\pi r) = \mu_0 I_0 \left[\frac{\left(R_3^3 - R_2^3\right)}{\left(R_3^3 - R_2^3\right)} - \frac{\left(R^3 - R_2^3\right)}{\left(R_3^3 - R_2^3\right)} \right] \rightarrow \boxed{B = \frac{\mu_0 I_0}{2\pi R} \frac{\left(R_3^3 - R^3\right)}{\left(R_3^3 - R_2^3\right)}}$$

(*d*) Outside the outer wire the net current enclosed is zero.



$$\oint \vec{\mathbf{B}} \cdot d\vec{s} = \mu_0 I_{\text{encl}} = 0 \;\rightarrow\; B(2\pi R) = 0 \;\rightarrow\; \boxed{B = 0}$$

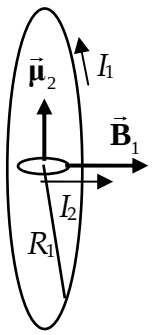
33. Use Eq. 28-7b to write a ratio of the magnetic fields at the surface of the earth and 13,000 km above the surface. Use the resulting ratio to determine the magnetic field above the surface.

$$\frac{B_2}{B_1}=\frac{\dfrac{\mu_0}{2\pi}\dfrac{\mu}{x_2^3}}{\dfrac{\mu_0}{2\pi}\dfrac{\mu}{x_1^3}}=\frac{x_1^3}{x_2^3} \quad \rightarrow \quad B_2=B_1\frac{x_1^3}{x_2^3}=\left(1.0\times10^{-4}\text{T}\right)\left(\frac{6.38\times10^3\text{km}}{19.38\times10^3\text{km}}\right)^3=\boxed{3.6\times10^{-6}\text{T}}$$

34. Since the point C is along the line of the two straight segments of the current, these segments do not contribute to the magnetic field at C. We calculate the magnetic field by integrating Eq. 28-5 along the two curved segments. Along each integration the line segment is perpendicular to the radial vector and the radial distance is constant.



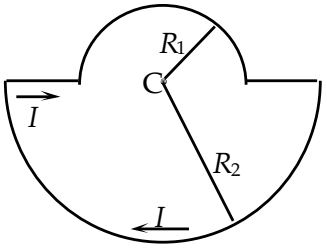
$$\vec{\mathbf{B}}=\frac{\mu_0 I}{4\pi}\int_0^{R_1\theta}\frac{d\vec{\ell}\times\hat{r}}{R_1^2}+\frac{\mu_0 I}{4\pi}\int_{R_2\theta}^{0}\frac{d\vec{\ell}\times\hat{r}}{R_2^2}=\frac{\mu_0 I}{4\pi R_1^2}\hat{\mathbf{k}}\int_0^{R_1\theta}ds+\frac{\mu_0 I}{4\pi R_2^2}\hat{\mathbf{k}}\int_{R_2\theta}^{0}ds$$

$$=\frac{\mu_0 I\theta}{4\pi R_1}\hat{\mathbf{k}}-\frac{\mu_0 I\theta}{4\pi R_2}\hat{\mathbf{k}}=\boxed{\frac{\mu_0 I\theta}{4\pi}\left(\frac{R_2-R_1}{R_1R_2}\right)\hat{\mathbf{k}}}$$

35. Since the current in the two straight segments flows radially toward and away from the center of the loop, they do not contribute to the magnetic field at the center. We calculate the magnetic field by integrating Eq. 28-5 along the two curved segments. Along each integration segment, the current is perpendicular to the radial vector and the radial distance is constant. By the right-hand-rule the magnetic field from the upper portion will point into the page and the magnetic field from the lower portion will point out of the page.

$$\vec{\mathbf{B}}=\frac{\mu_0 I_1}{4\pi}\int_{\text{upper}}\frac{ds}{R^2}\hat{\mathbf{k}}+\frac{\mu_0 I_2}{4\pi}\int_{\text{lower}}\frac{ds}{R^2}\left(-\hat{\mathbf{k}}\right)=\frac{\mu_0(\pi R)}{4\pi R^2}\hat{\mathbf{k}}\left(I_1-I_2\right)=\frac{\mu_0}{4R}\hat{\mathbf{k}}\left(0.35I-0.65I\right)=\boxed{-\frac{3\mu_0 I}{40R}}$$

36. We assume that the inner loop is sufficiently small that the magnetic field from the larger loop can be considered to be constant across the surface of the smaller loop. The field at the center of the larger loop is illustrated in Example 28-12. Use Eq. 27-10 to calculate the magnetic moment of the small loop, and Eq. 27-11 to calculate the torque.



$$\vec{\mathbf{B}}=\frac{\mu_0 I}{2R}\hat{\mathbf{i}} \qquad \vec{\boldsymbol{\mu}}=I\vec{\mathbf{A}}=I\pi R_2^2\hat{\mathbf{j}}$$

$$\vec{\boldsymbol{\tau}}=\vec{\boldsymbol{\mu}}\times\vec{\mathbf{B}}=I\pi R_2^2\hat{\mathbf{j}}\times\frac{\mu_0 I}{2R}\hat{\mathbf{i}}=-\frac{\mu_0\pi I^2R_2^2}{2R}\hat{\mathbf{k}}$$

$$=-\frac{\left(4\pi\times10^{-7}\ \text{T}\bullet\text{m/A}\right)\pi\left(7.0\ \text{A}\right)^2\left(0.018\ \text{m}\right)^2}{2\left(0.25\ \text{m}\right)}\hat{\mathbf{k}}=\boxed{-1.3\times10^{-7}\hat{\mathbf{k}}\ \text{m}\bullet\text{N}}$$

This torque would cause the inner loop to rotate into the same plane as the outer loop with the currents flowing in the same direction.

37. (*a*) The magnetic field at point C can be obtained using the Biot-Savart law (Eq. 28-5, integrated over the current). First break the loop into four sections: 1) the upper semi-circle, 2) the lower semi-circle, 3) the right straight segment, and 4) the left straight segment. The two straight segments do not contribute to the magnetic field as the point C is in the same direction that the

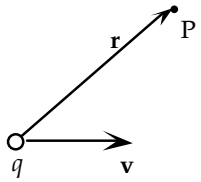
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

current is flowing. Therefore, along these segments $\hat{r}$ and $d\hat{\ell}$ are parallel and $d\hat{\ell}\times\hat{r}=0$. For the upper segment, each infinitesimal line segment is perpendicular to the constant magnitude radial vector, so the magnetic field points downward with constant magnitude.

$$\vec{\mathbf{B}}_{\text{upper}}=\int\frac{\mu_0 I}{4\pi}\frac{d\hat{\ell}\times\hat{r}}{r^2}=\frac{\mu_0 I}{4\pi}\frac{-\hat{k}}{R_1^{\,2}}(\pi R_1)=-\frac{\mu_0 I}{4R_1}\hat{k}\,.$$

Along the lower segment, each infinitesimal line segment is also perpendicular to the constant radial vector.

$$\vec{\mathbf{B}}_{\text{lower}}=\int\frac{\mu_0 I}{4\pi}\frac{d\hat{\ell}\times\hat{r}}{r^2}=\frac{\mu_0 I}{4\pi}\frac{-\hat{k}}{R_2^{\,2}}(\pi R_2)=-\frac{\mu_0 I}{4R_2}\hat{k}$$

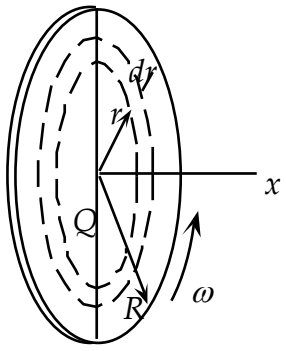


Adding the two contributions yields the total magnetic field.

$$\vec{\mathbf{B}}=\vec{\mathbf{B}}_{\text{upper}}+\vec{\mathbf{B}}_{\text{lower}}=-\frac{\mu_0 I}{4R_1}\hat{k}-\frac{\mu_0 I}{4R_2}\hat{k}=\boxed{-\frac{\mu_0 I}{4}\left(\frac{1}{R_1}+\frac{1}{R_2}\right)\hat{k}}$$

(*b*) The magnetic moment is the product of the area and the current. The area is the sum of the two half circles. By the right-hand-rule, curling your fingers in the direction of the current, the thumb points into the page, so the magnetic moment is in the $-\hat{k}$ direction.

$$\vec{\boldsymbol{\mu}}=-\left(\frac{\pi R_1^2}{2}+\frac{\pi R_2^2}{2}\right)I\hat{k}=\boxed{\frac{-\pi I}{2}\left(R_1^2+R_2^2\right)\hat{k}}$$



38. Treat the moving point charge as a small current segment. We can write the product of the charge and velocity as the product of a current and current segment. Inserting these into the Biot-Savart law gives us the magnetic field at point P.

$$q\vec{\mathbf{v}}=q\frac{d\vec{\ell}}{dt}=\frac{dq}{dt}d\vec{\ell}=Id\vec{\ell}$$

$$\vec{\mathbf{B}}=\frac{\mu_0 I}{4\pi}\frac{d\vec{\ell}\times\hat{r}}{r^2}=\frac{\mu_0}{4\pi}\frac{q\vec{\mathbf{v}}\times\hat{r}}{r^2}=\boxed{\frac{\mu_0}{4\pi}\frac{q\vec{\mathbf{v}}\times\vec{\mathbf{r}}}{r^3}}$$

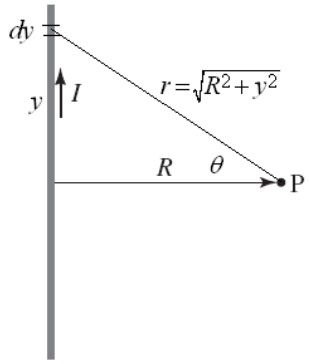
39. (*a*) The disk can be broken down into a series of infinitesimal thick rings. As the charge in each of these rings rotates it produces a current of magnitude $dI=(\omega/2\pi)dq$, where *dq* is the surface charge density multiplied by the area of the ring. We use Eq. 27-10 to calculate the magnetic dipole moment of each current loop and integrate the dipole moments to obtain the total magnetic dipole moment.

$$d\vec{\boldsymbol{\mu}}=dI\vec{\mathbf{A}}=\left(\frac{Q}{\pi R^2}2\pi r\,dr\,\frac{\omega}{2\pi}\right)(\pi r^2)=\frac{Q\omega}{R^2}r^3dr\hat{\mathbf{i}}$$

$$\vec{\boldsymbol{\mu}}=\int_0^R\frac{Q\omega}{R^2}r^3dr\,\hat{\mathbf{i}}=\boxed{\frac{Q\omega R^2}{4}\hat{\mathbf{i}}}$$

(*b*) To find the magnetic field a distance *x* along the axis of the disk, we again consider the disk as a series of concentric currents. We use the results of Example 28-12 to determine the magnetic field from each current loop in the disk, and then integrate to obtain the total magnetic field.

$$d\vec{\mathbf{B}}=\frac{\mu_0 r^2}{2\left(r^2+x^2\right)^{\frac{3}{2}}}dI=\frac{\mu_0 r^2}{2\left(r^2+x^2\right)^{\frac{3}{2}}}\frac{Q\omega}{\pi R^2}r\,dr$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

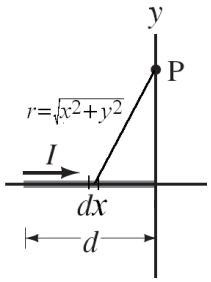
$$\vec{\mathbf{B}} = \frac{\mu_0 Q\omega\hat{\mathbf{i}}}{2\pi R^2}\int_0^R \frac{r^3}{\left(r^2+x^2\right)^{\frac{3}{2}}}dr = \frac{\mu_0 Q\omega\hat{\mathbf{i}}}{2\pi R^2}\frac{\left(r^2+2x^2\right)}{\sqrt{r^2+x^2}}\Bigg|_0^R = \boxed{\frac{\mu_0 Q\omega\hat{\mathbf{i}}}{2\pi R^2}\left[\frac{\left(R^2+2x^2\right)}{\sqrt{R^2+x^2}}-2x\right]}$$

(*c*) When we take the limit $x \gg R$ our equation reduces to Eq. 28-7b.

$$\vec{\mathbf{B}} \approx \frac{\mu_0 Q\omega\hat{\mathbf{i}}}{2\pi R^2}\left[2x\left(1+\frac{R^2}{2x^2}\right)\left(1-\frac{R^2}{2x^2}+\frac{3R^4}{8x^4}+\ldots\right)-2x\right] \approx \frac{\mu_0 Q\omega\hat{\mathbf{i}}}{2\pi R^2}\left(\frac{R^4}{4x^3}\right) = \boxed{\frac{\mu_0}{2\pi}\frac{\vec{\boldsymbol{\mu}}}{x^3}}$$

40. (*a*) Choose the *y* axis along the wire and the *x* axis passing from the center of the wire through the point P. With this definition we calculate the magnetic field at P by integrating Eq. 28-5 over the length of the wire. The origin is at the center of the wire.

$$\vec{\mathbf{B}} = \int \frac{\mu_0 I}{4\pi}\frac{d\vec{\ell}\times\hat{r}}{r^2} = \int \frac{\mu_0 I}{4\pi}\frac{d\vec{\ell}\times\vec{\mathbf{r}}}{r^3} = \frac{\mu_0 I}{4\pi}\int_{-\frac{1}{2}d}^{\frac{1}{2}d}\frac{dy\hat{\mathbf{j}}\times\left(R\hat{\mathbf{i}}-y\hat{\mathbf{j}}\right)}{\left(R^2+y^2\right)^{3/2}}$$



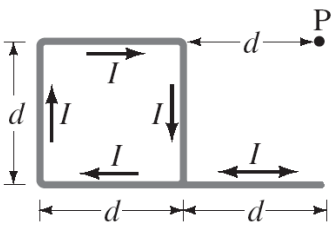
$$= -\frac{\mu_0 IR}{4\pi}\hat{\mathbf{k}}\int_{-\frac{1}{2}d}^{\frac{1}{2}d}\frac{dy}{\left(R^2+y^2\right)^{3/2}}$$

$$= -\frac{\mu_0 IR}{4\pi}\hat{\mathbf{k}}\frac{y}{R^2\left(R^2+y^2\right)^{1/2}}\Bigg|_{-d/2}^{d/2} = \boxed{-\frac{\mu_0 I}{2\pi R}\frac{d}{\left(4R^2+d^2\right)^{1/2}}\hat{\mathbf{k}}}$$

(*b*) If we take the limit as $d \to \infty$, this equation reduces to Eq. 28-1.

$$B = \lim_{d\to\infty}\left(\frac{\mu_0 I}{2\pi R}\frac{d}{\left(4R^2+d^2\right)^{1/2}}\right) \approx \frac{\mu_0 I}{2\pi R}$$

41. (*a*) The magnetic field at point Q can be obtained by integrating Eq. 28-5 over the length of the wire. In this case, each infinitesimal current segment dℓ is parallel to the *x* axis, as is each radial vector. Since the magnetic field is proportional to the cross-product of the current segment and the radial vector, each segment contributes zero field. Thus the magnetic field at point Q is zero.



(*b*) The magnetic field at point P is found by integrating Eq. 28-5 over the length of the current segment.

$$\vec{\mathbf{B}} = \int \frac{\mu_0 I}{4\pi}\frac{d\vec{\ell}\times\hat{r}}{r^2} = \int \frac{\mu_0 I}{4\pi}\frac{d\vec{\ell}\times\vec{\mathbf{r}}}{r^3} = \frac{\mu_0 I}{4\pi}\int_{-d}^{0}\frac{dx\hat{\mathbf{i}}\times\left(-x\hat{\mathbf{i}}+y\hat{\mathbf{j}}\right)}{\left(x^2+y^2\right)^{3/2}} = \frac{\mu_0 Iy}{4\pi}\hat{\mathbf{k}}\int_{-d}^{0}\frac{dx}{\left(x^2+y^2\right)^{3/2}}$$

$$= \frac{\mu_0 Iy}{4\pi}\hat{\mathbf{k}}\frac{x}{y^2\left(x^2+y^2\right)^{1/2}}\Bigg|_{-d}^{0} = \boxed{\frac{\mu_0 I}{4\pi y}\frac{d}{\left(y^2+d^2\right)^{1/2}}\hat{\mathbf{k}}}$$

42. We treat the loop as consisting of 5 segments, The first has length *d*, is located a distance *d* to the left of point P, and has current flowing toward the right. The second has length *d*, is located a distance 2*d* to left of point P, and has current flowing upward. The third has length *d*, is located a distance *d* to the left of point P, and has current flowing downward. The fourth has length 2*d*, is located a distance *d*

below point P, and has current flowing toward the left. Note that the fourth segment is twice as long as the actual fourth current. We therefore add a fifth line segment of length *d*, located a distance *d* below point P with current flowing to the right. This fifth current segment cancels the added portion, but allows us to use the results of Problem 41 in solving this problem. Note that the first line points radially toward point P, and therefore by Problem 41(*a*) does not contribute to the net magnetic field. We add the contributions from the other four segments, with the contribution in the positive *z*-direction if the current in the segment appears to flows counterclockwise around the point P.

$$\vec{\mathbf{B}} = \vec{\mathbf{B}}_2 + \vec{\mathbf{B}}_3 + \vec{\mathbf{B}}_4 + \vec{\mathbf{B}}_5$$

$$= -\frac{\mu_0 I}{4\pi(2d)}\frac{d}{\left(4d^2+d^2\right)^{1/2}}\hat{\mathbf{k}} + \frac{\mu_0 I}{4\pi d}\frac{d}{\left(d^2+d^2\right)^{1/2}}\hat{\mathbf{k}} - \frac{\mu_0 I}{4\pi d}\frac{2d}{\left(d^2+4d^2\right)^{1/2}}\hat{\mathbf{k}} + \frac{\mu_0 I}{4\pi d}\frac{d}{\left(d^2+d^2\right)^{1/2}}\hat{\mathbf{k}}$$

$$= \boxed{\frac{\mu_0 I}{4\pi d}\left(\sqrt{2} - \frac{\sqrt{5}}{2}\right)\hat{\mathbf{k}}}$$

43. (*a*) The angle subtended by one side of a polygon, θ, from the center point P is 2π divided by the number of sides, *n*. The length of the side *L* and the distance from the point to the center of the side, *D*, are obtained from trigonometric relations.

$$L = 2R\sin(\theta/2) = 2R\sin(\pi/n)$$

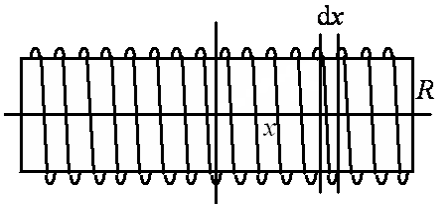
$$D = R\cos(\theta/2) = R\cos(\pi/n)$$

The magnetic field contribution from each side can be found using the result of Problem 40.

$$B = \frac{\mu_0 I}{2\pi D}\frac{L}{\left(L^2+4D^2\right)^{\frac{1}{2}}} = \frac{\mu_0 I}{2\pi\left(R\cos(\pi/n)\right)}\frac{2R\sin(\pi/n)}{\left(\left(2R\sin(\pi/n)\right)^2 + 4\left(R\cos(\pi/n)\right)^2\right)^{\frac{1}{2}}}$$

$$= \frac{\mu_0 I}{2\pi R}\tan(\pi/n)$$

The contributions from each segment add, so the total magnetic field is *n* times the field from one side.

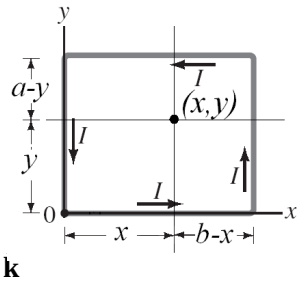


$$\boxed{B_{\text{total}} = \frac{\mu_0 In}{2\pi R}\tan(\pi/n)}$$

(*b*) In the limit of large *n*, π/n, becomes very small, so $\tan(\pi/n) \approx \pi/n$.

$$B_{\text{total}} = \frac{\mu_0 In}{2\pi R}\frac{\pi}{n} = \boxed{\frac{\mu_0 I}{2R}}$$

This is the magnetic field at the center of a circle.



44. The equation derived in Eq. 28-12 gives the magnetic field a distance *x* from a single loop. We expand this single loop to the field of an infinite solenoid by multiplying the field from a single loop by *n dx*, the density of loops times the infinitesimal thickness, and integrating over all values of *x*. Use the table in Appendix B-4 to evaluate the integral.

$$B = \int_{-\infty}^{\infty}\frac{\mu_0 IR^2 n\,dx}{2\left(R^2+x^2\right)^{\frac{3}{2}}} = \frac{\mu_0 IR^2 n}{2}\int_{-\infty}^{\infty}\frac{dx}{\left(R^2+x^2\right)^{\frac{3}{2}}} = \frac{\mu_0 IR^2 n}{2}\left.\frac{x}{R^2\left(R^2+x^2\right)^{\frac{1}{2}}}\right|_{-\infty}^{\infty} = \boxed{\mu_0 In}$$

45. To find the magnetic field at point (x,y) we break each current segment into two segments and sum fields from each of the eight segments to determine the magnetic field at the center. We use the results of Problem 41(b) to calculate the magnetic field of each segment.

$$\vec{\mathbf{B}} = \frac{\mu_0 I}{4\pi y}\frac{x}{\left(y^2+x^2\right)^{1/2}}\hat{\mathbf{k}} + \frac{\mu_0 I}{4\pi y}\frac{(b-x)}{\left(y^2+(b-x)^2\right)^{1/2}}\hat{\mathbf{k}}$$
$$+\frac{\mu_0 I}{4\pi(b-x)}\frac{y}{\left((b-x)^2+y^2\right)^{1/2}}\hat{\mathbf{k}} + \frac{\mu_0 I}{4\pi(b-x)}\frac{(a-y)}{\left((a-y)^2+(b-x)^2\right)^{1/2}}\mathbf{k}$$
$$+\frac{\mu_0 I}{4\pi(a-y)}\frac{(b-x)}{\left((a-y)^2+(b-x)^2\right)^{1/2}}\hat{\mathbf{k}} + \frac{\mu_0 I}{4\pi(a-y)}\frac{x)}{\left((a-y)^2+x^2\right)^{1/2}}\hat{\mathbf{k}}$$
$$+\frac{\mu_0 I}{4\pi x}\frac{(a-y)}{\left((a-y)^2+x^2\right)^{1/2}}\hat{\mathbf{k}} + \frac{\mu_0 I}{4\pi x}\frac{y}{\left(y^2+x^2\right)^{1/2}}\hat{\mathbf{k}}$$

We simplify this equation by factoring out common constants and combining terms with similar roots.

$$\boxed{\vec{\mathbf{B}} = \frac{\mu_0 I}{4\pi}\left(\frac{\sqrt{y^2+x^2}}{xy} + \frac{\sqrt{y^2+(b-x)^2}}{(b-x)y} + \frac{\sqrt{(a-y)^2+(b-x)^2}}{(a-y)(b-x)} + \frac{\sqrt{(a-y)^2+x^2}}{x(a-y)}\right)\hat{\mathbf{k}}}$$

46. (*a*) By symmetry we see that on the x axis the magnetic field can only have an x component. To justify this assertion, imagine that the magnetic field had a component off the axis. If the current loop were rotated by 90° about the x axis, the loop orientation would be identical to the original loop, but the off-axis magnetic field component would have changed. This is not possible, so the field only has an x component. The contribution to this field is the same for each loop segment, and so the total magnetic field is equal to 4 times the x component of the magnetic field from one segment. We integrate Eq. 28-5 to find this magnetic field.

$$\vec{\mathbf{B}} = 4\int_{-\frac{1}{2}d}^{\frac{1}{2}d}\frac{\mu_0 I}{4\pi}\frac{dy\,\hat{\mathbf{j}}\times\left(\frac{1}{2}d\,\hat{\mathbf{k}}\right)}{\left[\left(\frac{1}{2}d\right)^2+x^2+y^2\right]^{3/2}} = \frac{\mu_0 I d\,\hat{\mathbf{i}}}{2\pi}\int_{-\frac{1}{2}d}^{\frac{1}{2}d}\frac{dy}{\left[\left(\frac{1}{2}d\right)^2+x^2+y^2\right]^{3/2}}$$
$$= \frac{\mu_0 I d\,\hat{\mathbf{i}}}{2\pi}\frac{y}{\left[\left(\frac{1}{2}d\right)^2+x^2\right]\left[\left(\frac{1}{2}d\right)^2+x^2+y^2\right]^{1/2}}\Bigg|_{-\frac{1}{2}d}^{\frac{1}{2}d} = \boxed{\frac{2\sqrt{2}d^2\mu_0 I\,\hat{\mathbf{i}}}{\pi\left(d^2+4x^2\right)\left(d^2+2x^2\right)^{1/2}}}$$

(*b*) Let $x \gg d$ to show that the magnetic field reduces to a dipole field of Eq. 28-7b.

$$\vec{\mathbf{B}} \approx \frac{2\sqrt{2}d^2\mu_0 I\,\hat{\mathbf{i}}}{\pi\left(4x^2\right)\left(2x^2\right)^{1/2}} = \frac{d^2\mu_0 I\,\hat{\mathbf{i}}}{2\pi x^3}$$

Comparing our magnetic field to Eq. 28-7b we see that it is a dipole field with the magnetic moment $\boxed{\vec{\boldsymbol{\mu}} = d^2 I\,\hat{\mathbf{i}}}$

47. (*a*) If the iron bar is completely magnetized, all of the dipoles are aligned. The total dipole moment is equal to the number of atoms times the dipole moment of a single atom.

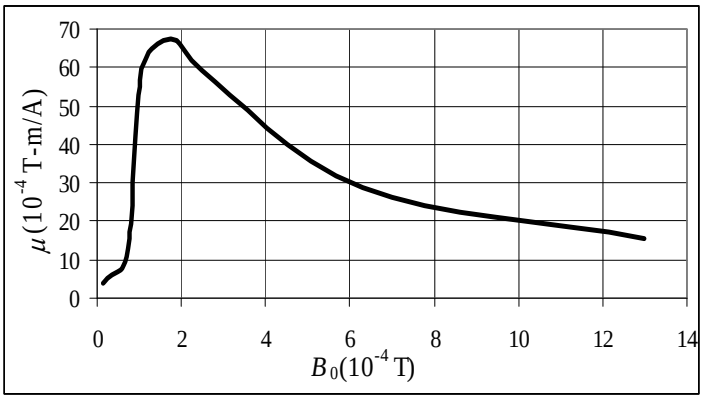
$$\mu = N\mu_1 = \frac{N_A\rho V}{M_m}\mu_1$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \frac{(6.022\times10^{23}\,\text{atoms/mole})(7.80\,\text{g/cm}^3)(9.0\,\text{cm})(1.2\,\text{cm})(1.0\,\text{cm})}{55.845\,\text{g/mole}}\left(1.8\times10^{-23}\,\frac{\text{A}\bullet\text{m}^2}{\text{atom}}\right)$$

$$= 16.35\ \text{A}\bullet\text{m}^2 \approx \boxed{16\ \text{A}\bullet\text{m}^2}$$

(*b*) We use Eq. 27-9 to find the torque.



$$\tau = \mu B\sin\theta = (16.35\ \text{A}\bullet\text{m}^2)(0.80\ \text{T})\sin 90° = \boxed{13\ \text{m}\bullet\text{N}}$$

48. The magnetic permeability is found from the two fields.

$$B_0 = \mu_0 nI \ ;\ B = \mu nI \ ;$$

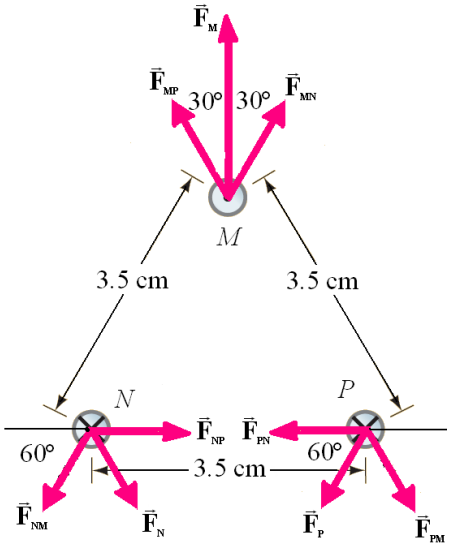
$$\frac{B}{B_0} = \frac{\mu}{\mu_0} \ \rightarrow\ \mu = \mu_0\frac{B}{B_0}$$

For the graph, we have not plotted the last three data points so that the structure for low fields is seen. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH28.XLS," on tab "Problem 28.48."

49. The magnetic field of a long, thin torus is the same as the field given by a long solenoid, as in Eq. 28-9.

$$B = \mu nI = (2200)(4\pi\times10^{-7}\ \text{Tm/A})(285\ \text{m}^{-1})(3.0\ \text{A}) = \boxed{2.4\ \text{T}}$$

50. The field inside the solenoid is given by Eq. 28-4 with μ_0 replaced by the permeability of the iron.



$$B = \frac{\mu NI}{\ell} \ \rightarrow\ \mu = \frac{B\ell}{NI} = \frac{(2.2\,\text{T})(0.38\,\text{m})}{(640)(48\,\text{A})} = \boxed{2.7\times10^{-5}\,\text{T}\bullet\text{m/A}} \approx 22\mu_0$$

51. Since the wires all carry the same current and are equidistant from each other, the magnitude of the force per unit length between any two wires is the same and is given by Eq. 28-2.

$$\frac{F}{\ell} = \frac{\mu_0 I^2}{2\pi d} = \frac{(4\pi\times10^{-7}\ \text{T}\bullet\text{m/A})(8.00\ \text{A})^2}{2\pi(0.035\ \text{m})}$$

$$= 3.657\times10^{-4}\ \text{N/m}$$

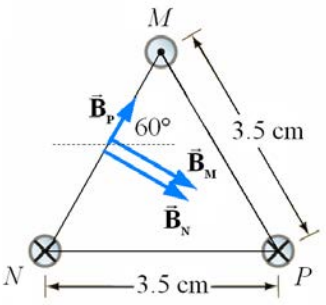
The direction of the force between two wires is along the radial line and attractive for currents traveling in the same direction and repulsive for currents traveling in opposite directions. The forces acting on wire M are radially away from the other two wires. By symmetry, the horizontal components of these forces cancel and the net force is the sum of the vertical components.

$$F_M = F_{MP}\cos 30° + F_{MN}\cos 30°$$

$$= 2(3.657\times10^{-4}\ \text{N/m})\cos 30° = \boxed{6.3\times10^{-4}\ \text{N/m at 90°}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The force on wire N is found by adding the components of the forces from the other two wires. By symmetry we see that this force is directed at an angle of 300°. The force on wire P, will have the same magnitude but be directed at 240°.



$$F_{N,x} = F_{NP} - F_{NM}\cos 60° = 3.657\times10^{-4}\ \text{N/m} - \left(3.657\times10^{-4}\ \text{N/m}\right)\cos 60° = 1.829\times10^{-4}\ \text{N/m}$$

$$F_{N,y} = -F_{NM}\sin 60° = -\left(3.657\times10^{-4}\ \text{N/m}\right)\sin 60° = -3.167\times10^{-4}\ \text{N/m}$$

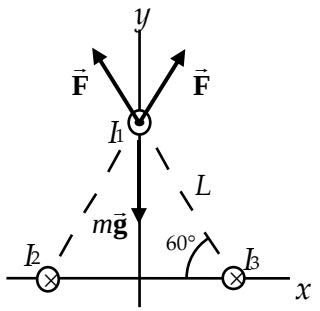
$$F_N = \sqrt{\left(1.829\times10^{-4}\ \text{N/m}\right)^2 + \left(-3.167\times10^{-4}\ \text{N/m}\right)^2} = \boxed{3.7\times10^{-4}\ \text{N/m at 300°}}$$

$$F_P = \boxed{3.7\times10^{-4}\ \text{N/m at 240°}}$$

52. The magnetic field at the midpoint between currents M and N is the vector sum of the magnetic fields from each wire, given by Eq. 28-1. Each field points perpendicularly to the line connecting the wire to the midpoint.

$$\vec{\mathbf{B}}_{\text{net}} = \vec{\mathbf{B}}_M + \vec{\mathbf{B}}_N + \vec{\mathbf{B}}_P$$

$$B_M = B_N = \frac{\mu_0}{2\pi}\frac{I}{r_M} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)}{2\pi}\frac{8.00\ \text{A}}{0.0175\ \text{m}} = 9.143\times10^{-5}\ \text{T}$$



$$B_P = \frac{\mu_0}{2\pi}\frac{I}{r_P} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)}{2\pi}\frac{8.00\ \text{A}}{\sqrt{3}\left(0.0175\ \text{m}\right)} = 5.279\times10^{-5}\ \text{T}$$

$$B_{\text{net}} = \sqrt{B_{\text{net}\,x}^2 + B_{\text{net}\,y}^2} = \sqrt{\left(1.849\times10^{-4}\ \text{T}\right)^2 + \left(-4.571\times10^{-5}\ \text{T}\right)} = \boxed{4.93\times10^{-4}\ \text{T}}$$

$$\theta_{\text{net}} = \tan^{-1}\frac{B_{\text{net}\,y}}{B_{\text{net}\,y}} = \tan^{-1}\frac{-4.210\times10^{-5}\ \text{T}}{1.702\times10^{-4}\ \text{T}} = \boxed{-14°}$$

The net field points slightly below the horizontal direction.

53. For the wire to be suspended the net magnetic force must equal the gravitational force. Since the same current flows through the two lower wires, the net magnetic force is the sum of the vertical components of the force from each wire, given by Eq. 28-2. We solve for the unknown current by setting this force equal to the weight of the wire.

$$F_M = 2\frac{\mu_0 I_M I_{NP}}{2\pi r}\ell\cos 30° = \rho g\left(\tfrac{1}{4}\pi d^2\ell\right)$$

$$I_M = \frac{\rho g\pi^2 r d^2}{4\mu_0 I_{NP}\cos 30°}$$

$$= \frac{\left(8900\ \text{kg/m}^3\right)\left(9.80\ \text{m/s}^2\right)\pi^2\left(0.035\ \text{m}\right)\left(1.00\times10^{-3}\ \text{m}\right)^2}{4\left(4\pi\times10^{-7}\ \text{T•m/A}\right)\left(40.0\ \text{A}\right)\cos 30°} = \boxed{170\ \text{A}}$$

54. The centripetal force is caused by the magnetic field, and is given by Eq. 27-5b. From this force we can calculate the radius of curvature.

$$F = qvB\sin\theta = qv_\perp B = m\frac{v_\perp^2}{r} \quad \rightarrow$$

$$r = \frac{mv_\perp}{qB} = \frac{\left(9.11\times10^{-31}\ \text{kg}\right)\left(1.3\times10^7\ \text{m/s}\right)\sin 7°}{\left(1.60\times10^{-19}\ \text{C}\right)\left(3.3\times10^{-2}\ \text{T}\right)} = 2.734\times10^{-4}\ \text{m} \approx \boxed{0.27\ \text{mm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The component of the velocity that is parallel to the magnetic field is unchanged, and so the pitch is that velocity component times the period of the circular motion.

$$T = \frac{2\pi r}{v_\perp} = \frac{2\pi \dfrac{mv_\perp}{qB}}{v_\perp} = \frac{2\pi m}{qB}$$

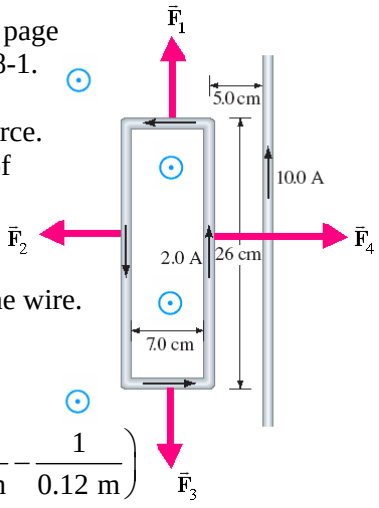
$$p = v_\parallel T = v\cos 7^\circ\left(\frac{2\pi m}{qB}\right) = \left(1.3\times10^7\ \text{m/s}\right)\cos 7^\circ \frac{2\pi\left(9.11\times10^{-31}\text{kg}\right)}{\left(1.60\times10^{-19}\text{C}\right)\left(3.3\times10^{-2}\ \text{T}\right)} = \boxed{1.4\ \text{cm}}$$

55. (*a*) Use Eq. 28-1 to calculate the field due to a long straight wire.

$$B_{\text{A at B}} = \frac{\mu_0 I_\text{A}}{2\pi r_{\text{A to B}}} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)\left(2.0\,\text{A}\right)}{2\pi\left(0.15\,\text{m}\right)} = 2.667\times10^{-6}\,\text{T} \approx \boxed{2.7\times10^{-6}\,\text{T}}$$

(*b*) $B_{\text{B at A}} = \dfrac{\mu_0 I_\text{B}}{2\pi r_{\text{B to A}}} = \dfrac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)\left(4.0\,\text{A}\right)}{2\pi\left(0.15\,\text{m}\right)} = 5.333\times10^{-6}\,\text{T} \approx \boxed{5.3\times10^{-6}\,\text{T}}$

(*c*) The two fields are not equal and opposite. Each individual field is due to a single wire, and has no dependence on the other wire. The magnitude of current in the second wire has nothing to do with the value of the field caused by the first wire.



(*d*) Use Eq. 28-2 to calculate the force due to one wire on another. The forces are attractive since the currents are in the same direction.

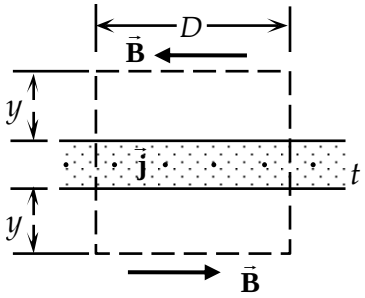
$$\frac{F_{\text{on A due to B}}}{\ell_\text{A}} = \frac{F_{\text{on B due to A}}}{\ell_\text{B}} = \frac{\mu_0}{2\pi}\frac{I_\text{A}I_\text{B}}{d_{\text{A to B}}} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)}{2\pi}\frac{\left(2.0\,\text{A}\right)\left(4.0\,\text{A}\right)}{\left(0.15\,\text{m}\right)}$$

$$= 1.067\times10^{-5}\ \text{N/m} \approx \boxed{1.1\times10^{-5}\ \text{N/m}}$$

These two forces per unit length are equal and opposite because they are a Newton's third law pair of forces.

56. (*a*) The magnetic field from the long straight wire will be out of the page in the region of the wire loop with its magnitude given by Eq. 28-1. By symmetry, the forces from the two horizontal segments are equal and opposite, therefore they do not contribute to the net force. We use Eq. 28-2 to find the force on the two vertical segments of the loop and sum the results to determine the net force. Note that the segment with the current parallel to the straight wire will be attracted to the wire, while the segment with the current flowing in the opposite direction will be repelled from the wire.

$$F_{net} = F_2 + F_4 = -\frac{\mu_0 I_1 I_2}{2\pi d_2}\ell + \frac{\mu_0 I_1 I_2}{2\pi d_1}\ell = \frac{\mu_0 I_1 I_2 \ell}{2\pi}\left(\frac{1}{d_1} - \frac{1}{d_2}\right)$$



$$= \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)\left(2.0\ \text{A}\right)\left(10.0\ \text{A}\right)\left(0.26\ \text{m}\right)}{2\pi}\left(\frac{1}{0.05\ \text{m}} - \frac{1}{0.12\ \text{m}}\right)$$

$$= \boxed{1.2\times10^{-5}\ \text{N toward the wire}}$$

(*b*) Since the forces on each segment lie in the same plane, the net torque on the loop is zero.

57. The sheet may be treated as an infinite number of parallel wires. The magnetic field at a location *y* above the wire will be the sum of the magnetic fields produced by each of the wires. If we consider the magnetic field from two wires placed symmetrically on either side of where we are measuring the magnetic field, we see that the vertical magnetic field components cancel each other out. Therefore, the field above the wire must be horizontal and to the left. By symmetry, the field a location *y* below the wire must have the same magnitude, but point in the opposite direction. We calculate the magnetic field using Ampere's law with a rectangular loop that extends a distance *y* above and below the current sheet, as shown in the figure.

$$\oint \vec{\mathbf{B}} \cdot d\vec{\ell} = \int_{\text{sides}} \vec{\mathbf{B}} \cdot d\vec{\ell} + \int_{\text{top}} \vec{\mathbf{B}} \cdot d\vec{\ell} + \int_{\text{bottom}} \vec{\mathbf{B}} \cdot d\vec{\ell} = 0 + 2B_{\parallel} D = \mu_0 I_{\text{encl}} = \mu_0 (jtD)$$

$$\rightarrow B_{\parallel} = \boxed{\tfrac{1}{2}\mu_0 jt, \text{ to the left above the sheet}}$$

58. (*a*) We set the magnetic force, using Eq. 28-2, equal to the weight of the wire and solve for the necessary current. The current must flow in the same direction as the upper current, for the magnetic force to be upward.

$$F_M = \frac{\mu_0 I_1 I_2}{2\pi r}\ell = \rho g\left(\frac{\pi d^2}{4}\ell\right) \rightarrow$$

$$I_2 = \frac{\rho g \pi^2 r d^2}{4\mu_0 I_1} = \frac{\left(8900\,\text{kg/m}^3\right)\left(9.80\,\text{m/s}^2\right)\pi^2\left(0.050\,\text{m}\right)\left(1.00\times10^{-3}\,\text{m}\right)^2}{2\left(4\pi\times10^{-7}\,\text{T•m/A}\right)\left(48.0\,\text{A}\right)} = \boxed{360\,\text{A, right}}$$

(*b*) The lower wire is in unstable equilibrium, since if it is raised slightly from equilibrium, the magnetic force would be increased, causing the wire to move further from equilibrium.

(*c*) If the wire is suspended above the first wire at the same distance, the same current is needed, but in the opposite direction, as the wire must be repelled from the lower wire to remain in equilibrium. Therefore the current must be 360 A to the left. This is a stable equilibrium for vertical displacement since if the wire is moved slightly off the equilibrium point the magnetic force will increase or decrease to push the wire back to the equilibrium height.

59. The magnetic field at the center of the square loop is four times the magnetic field from one of the sides. It will be directed out of the page. We can use the result of Problem 40 for the magnitude of the field from one side, with $R = \frac{1}{2}d$. If the current is flowing counterclockwise around the square loop, the magnetic field due to each piece will point upwards.

$$\vec{\mathbf{B}}_{\substack{\text{one}\\\text{wire}}} = \frac{\mu_0 I}{2\pi R}\frac{d\,\hat{\mathbf{k}}}{\left(4R^2+d^2\right)^{1/2}} = \frac{\mu_0 I}{2\pi\left(\frac{1}{2}d\right)}\frac{d\,\hat{\mathbf{k}}}{\left(4\left(\frac{1}{2}d\right)^2+d^2\right)^{1/2}} = \frac{\mu_0 I}{\sqrt{2}\pi d}\hat{\mathbf{k}}$$

$$\vec{\mathbf{B}}_{\text{total}} = 4\vec{\mathbf{B}}_{\substack{\text{one}\\\text{wire}}} = \boxed{\frac{2\sqrt{2}\mu_0 I}{\pi d}\hat{\mathbf{k}}}$$

60. The magnetic field at the center of a circular loop was calculated in Example 28-12. To determine the radius of the loop, we set the circumferences of the loops equal.

$$2\pi R = 4d \rightarrow R = \frac{2d}{\pi} \;;\; B_{\text{circle}} = \frac{\mu_0 I}{2R} = \frac{\mu_0 I\pi}{4d} < \frac{2\sqrt{2}\mu_0 I}{\pi d} = B_{\text{square}}$$

Therefore, changing the shape to a circular loop will decrease the magnetic field.

61. (*a*) Choose $x = 0$ at the center of one coil. The center of the other coil will then be at $x = R$. Since the currents flow in the same direction in both coils, the right-hand-rule shows that the magnetic fields from the two coils will point in the same direction along the axis. The magnetic field from a current loop was found in Example 28-12. Adding the two magnetic fields together yields the total field.

$$B(x) = \boxed{\frac{\mu_0 NIR^2}{2\left[R^2 + x^2\right]^{3/2}} + \frac{\mu_0 NIR^2}{2\left[R^2 + (x-R)^2\right]^{3/2}}}$$

(*b*) Evaluate the derivative of the magnetic field at $x = \frac{1}{2}R$.

$$\frac{dB}{dx} = -\frac{3\mu_0 NIR^2 x}{2\left[R^2 + x^2\right]^{5/2}} - \frac{3\mu_0 NIR^2 (x-R)}{2\left[R^2 + (x-R)^2\right]^{5/2}} = -\frac{3\mu_0 NIR^3}{4\left[R^2 + R^2/4\right]^{5/2}} - \frac{-3\mu_0 NIR^3}{4\left[R^2 + R^2/4\right]^{5/2}} = \boxed{0}$$

Evaluate the second derivative of the magnetic field at $x = \frac{1}{2}R$.

$$\frac{d^2B}{dx^2} = -\frac{3\mu_0 NIR^2}{2\left[R^2 + x^2\right]^{5/2}} + \frac{15\mu_0 NIR^2 x^2}{2\left[R^2 + x^2\right]^{7/2}} - \frac{3\mu_0 NIR^2}{2\left[R^2 + (x-R)^2\right]^{5/2}} + \frac{15\mu_0 NIR^2 (x-R)^2}{2\left[R^2 + (x-R)^2\right]^{7/2}}$$

$$= -\frac{3\mu_0 NIR^2}{2\left[5R^2/4\right]^{5/2}} + \frac{15\mu_0 NIR^4}{8\left[5R^2/4\right]^{7/2}} - \frac{3\mu_0 NIR^2}{2\left[5R^2/4\right]^{5/2}} + \frac{15\mu_0 NIR^4}{8\left[5R^2/4\right]^{7/2}}$$

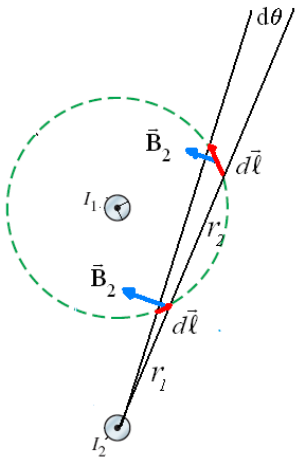
$$= \frac{\mu_0 NIR^2}{\left[5R^2/4\right]^{5/2}}\left(-\frac{3}{2} + \frac{15\cdot 4}{8\cdot 5} - \frac{3}{2} + \frac{15\cdot 4}{8\cdot 5}\right) = \boxed{0}$$

Therefore, at the midpoint $\frac{dB}{dx} = 0$ and $\frac{d^2B}{dx^2} = 0$.

(*c*) We insert the given data into the magnetic field equation to calculate the field at the midpoint.

$$B\left(\tfrac{1}{2}R\right) = \frac{\mu_0 NIR^2}{2\left[R^2 + \left(\frac{1}{2}R\right)^2\right]^{3/2}} + \frac{\mu_0 NIR^2}{2\left[R^2 + \left(\frac{1}{2}R\right)^2\right]^{3/2}} = \frac{\mu_0 NIR^2}{\left[R^2 + \left(\frac{1}{2}R\right)^2\right]^{3/2}}$$

$$= \frac{\left(4\pi\times 10^{-7}\ \text{T}\cdot\text{m/A}\right)(250)(2.0\,\text{A})(0.10\,\text{m})^2}{\left[(0.10\,\text{m})^2 + (0.05\,\text{m})^2\right]^{3/2}} = \boxed{4.5\,\text{mT}}$$



62. The total field is the vector sum of the fields from the two currents. We can therefore write the path integral as the sum of two such integrals.

$$\oint \vec{\mathbf{B}}\cdot d\vec{\ell} = \oint \vec{\mathbf{B}}_1\cdot d\vec{\ell} + \oint \vec{\mathbf{B}}_2\cdot d\vec{\ell}$$

To evaluate the integral for current 1, we use Eq. 28-1, with the magnetic field constant and parallel to the loop at each line segment.

$$\oint \vec{\mathbf{B}}_1\cdot d\vec{\ell} = \frac{\mu_0 I_1}{2\pi r}\int_0^{2\pi} r\,d\theta = \mu_0 I_1$$

To evaluate the integral for current 2, we consider a different angle $d\theta$ centered at I_2 and crossing the path of the loop at two locations, as shown in the diagram. If we integrate clockwise around the path, the components of $d\ell$ parallel to the field will be $-r_1 d\theta$ and $r_2 d\theta$. Multiplying these components by the magnetic field at both locations gives the contribution to the integral from the sum of these segments.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$B_1 d\ell_1 + B_2 d\ell_2 = \frac{\mu_0 I_2}{2\pi r_1}\left(-r_1 d\theta\right) + \frac{\mu_0 I_2}{2\pi r_2}\left(r_2 d\theta\right) = 0$$

The total integral will be the sum of these pairs resulting in a zero net integral.

$$\oint \vec{\mathbf{B}} \bullet d\vec{\ell} = \oint \vec{\mathbf{B}}_1 \bullet d\vec{\ell} + \oint \vec{\mathbf{B}}_2 \bullet d\vec{\ell} = \mu_0 I_1 + 0 = \boxed{\mu_0 I_1}$$

63. From Example 28-12, the magnetic field on the axis of a circular loop of wire of radius R carrying current I is $B = \dfrac{\mu_0 I R^2}{2\left(R^2 + x^2\right)^{3/2}}$, where *x* is the distance along the axis from the center of the loop.

For the loop described in this problem, we have $R = x = R_{\text{Earth}}$.

$$B = \frac{\mu_0 I R^2}{2\left(R^2 + x^2\right)^{3/2}} \quad \rightarrow \quad I = \frac{2B\left(R^2 + x^2\right)^{3/2}}{\mu_0 R^2} = \frac{2B\left(R_{\text{Earth}}^2 + R_{\text{Earth}}^2\right)^{3/2}}{\mu_0 R_{\text{Earth}}^2} = \frac{2\left(2\right)^{3/2} B R_{\text{Earth}}}{\mu_0}$$

$$= \frac{2\left(2\right)^{3/2}\left(1\times10^{-4}\,\text{T}\right)\left(6.38\times10^{6}\,\text{m}\right)}{4\pi\times10^{-7}\,\text{T}\bullet\text{m/A}} = \boxed{3\times10^{9}\,\text{A}}$$

64. The magnetic field from the wire at the location of the plane is perpendicular to the velocity of the plane since the plane is flying parallel to the wire. We calculate the force on the plane, and thus the acceleration, using Eq. 27-5b, with the magnetic field of the wire given by Eq. 28-1.

$$F = qvB = qv\frac{\mu_0 I}{2\pi r}$$

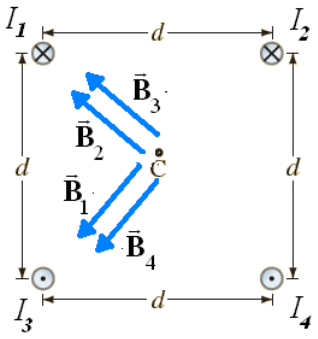
$$a = \frac{F}{m} = \frac{qv}{m}\frac{\mu_0 I}{2\pi r} = \frac{\left(18\times10^{-3}\ \text{C}\right)\left(2.8\ \text{m/s}\right)\left(4\pi\times10^{-7}\ \text{T}\bullet\text{m/A}\right)\left(25\ \text{A}\right)}{2\pi\left(0.175\ \text{kg}\right)\left(0.086\ \text{m}\right)}$$

$$= 1.67\times10^{-5}\ \text{m/s}^2 = \boxed{1.7\times10^{-6}\,g\text{'s}}$$

65. (*a*) To find the length of wire that will give the coil sufficient resistance to run at maximum power, we write the power equation (Eq. 25-7b) with the resistance given by Eq. 25-3. We divide the length by the circumference of one coil to determine the number of turns.

$$P_{\max} = \frac{V^2}{R} = \frac{V^2}{\rho\ell/\left(d^2\right)} \rightarrow \ell = \frac{V^2 d^2}{\rho P_{\max}}$$

$$N = \frac{\ell}{\pi D} = \frac{V^2 d^2}{\pi D \rho P_{\max}} = \frac{\left(35\ \text{V}\right)^2\left(2.0\times10^{-3}\ \text{m}\right)^2}{\pi\left(2.0\ \text{m}\right)\left(1.68\times10^{-8}\ \Omega\text{m}\right)\left(1.0\times10^{3}\ \text{W}\right)} = \boxed{46\ \text{turns}}$$



(*b*) We use the result of Example 28-12 to determine the magnetic field at the center of the coil, with the current obtained from Eq. 25-7b.

$$B = \frac{\mu_0 N I}{D} = \frac{\mu_0 N}{D}\frac{P_{\max}}{V} = \frac{\left(4\pi\times10^{-7}\ \text{T}\bullet\text{m/A}\right)\left(46\right)\left(1.0\times10^{3}\ \text{W}\right)}{\left(2.0\ \text{m}\right)\left(35\ \text{V}\right)} = \boxed{0.83\ \text{mT}}$$

(*c*) Increasing the number of turns will proportionately increase the resistance and therefore decrease the current. The net result is no change in the magnetic field.

66. The magnetic field at the center of the square is the vector sum of the magnetic field created by each current. Since the magnitudes of the currents are equal and the distance from each corner to the center is the same, the magnitude of the magnetic field from each wire is the same and is given by Eq. 28-1. The direction of the magnetic field is directed by the right-hand-rule and is shown in the diagram. By symmetry, we see that the vertical components of the magnetic field cancel and the horizontal components add.

$$\vec{\mathbf{B}} = \vec{\mathbf{B}}_1 + \vec{\mathbf{B}}_2 + \vec{\mathbf{B}}_3 + \vec{\mathbf{B}}_4 = -4\left(\frac{\mu_0 I}{2\pi r}\right)\cos 45°\hat{\mathbf{i}}$$

$$= -4\left(\frac{\mu_0 I}{2\pi\dfrac{\sqrt{2}}{2}d}\right)\frac{\sqrt{2}}{2}\hat{\mathbf{i}} = \boxed{-\frac{2\mu_0 I}{\pi d}\hat{\mathbf{i}}}$$

67. The wire can be broken down into five segments: the two long wires, the left vertical segment, the right vertical segment, and the top horizontal segment. Since the current in the two long wires either flow radially toward or away from the point P, they will not contribute to the magnetic field. The magnetic field from the top horizontal segment points into the page and is obtained from the solution to Problem 40.

$$B_{top} = \frac{\mu_0 I}{2\pi a}\frac{a}{\left(a^2 + 4a^2\right)^{\frac{1}{2}}} = \frac{\mu_0 I}{2\pi a\sqrt{5}}$$

The magnetic fields from the two vertical segments both point into the page with magnitudes obtained from the solution to Problem 41.

$$B_{vert} = \frac{\mu_0 I}{4\pi(a/2)}\frac{a}{\left(a^2 + (a/2)^2\right)^{\frac{1}{2}}} = \frac{\mu_0 I}{\pi a\sqrt{5}}$$

Summing the magnetic fields from all the segments yields the net field.

$$B = B_{top} + 2B_{vert} = \frac{\mu_0 I}{2\pi a\sqrt{5}} + 2\frac{\mu_0 I}{\pi a\sqrt{5}} = \boxed{\frac{\mu_0 I\sqrt{5}}{2\pi a}, \text{ into the page.}}$$

68. Use Eq. 28-4 for the field inside a solenoid.

$$B = \frac{\mu_0 IN}{\ell} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(2.0\,\text{A})(420)}{0.12\,\text{m}} = \boxed{8.8\times10^{-3}\,\text{T}}$$

69. The field due to the solenoid is given by Eq. 28-4. Since the field due to the solenoid is perpendicular to the current in the wire, Eq. 27-2 can be used to find the force on the wire segment.

$$F = I_{\text{wire}}\ell_{\text{wire}}B_{\text{solenoid}} = I_{\text{wire}}\ell_{\text{wire}}\frac{\mu_0 I_{\text{solenoid}}N}{\ell_{\text{solenoid}}} = (22\,\text{A})(0.030\text{m})\frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(33\,\text{A})(550)}{(0.15\,\text{m})}$$

$$= \boxed{0.10\,\text{N to the south}}$$

70. Since the mass of copper is fixed and the density is fixed, the volume is fixed, and we designate it as $V_{\text{Cu}} = m_{\text{Cu}}\rho_{\text{Cu}} = \ell_{\text{Cu}}A_{\text{Cu}}$. We call the fixed voltage V_0. The magnetic field in the solenoid is given by Eq. 28-4.

$$B = \frac{\mu_0 IN}{\ell_{\text{sol}}} = \mu_0 V_0 \frac{N}{R_{\text{Cu}}\ell_{\text{sol}}} = \frac{\mu_0 V_0}{\rho_{\text{RCu}}} \frac{N}{\frac{\ell_{\text{Cu}}}{A_{\text{Cu}}}\ell_{\text{sol}}} = \frac{\mu_0 V_0}{\rho_{\text{RCu}}} \frac{N}{\ell_{\text{sol}}} \frac{A_{\text{Cu}}}{\ell_{\text{Cu}}} = \frac{\mu_0 V_0}{\rho_{\text{RCu}}} \frac{N}{\ell_{\text{sol}}} \frac{m_{\text{Cu}}\rho_{\text{Cu}}}{\ell_{\text{Cu}}^2}$$

$$= \frac{\mu_0 V_0 m_{\text{Cu}}\rho_{\text{Cu}}}{\rho_{\text{RCu}}} \frac{N}{\ell_{\text{sol}}\ell_{\text{Cu}}^2}$$

The number of turns of wire is the length of wire divided by the circumference of the solenoid.

$$N = \frac{\ell_{\text{Cu}}}{2\pi r_{\text{sol}}} \quad \rightarrow \quad B = \frac{\mu_0 V_0 m_{\text{Cu}}\rho_{\text{Cu}}}{\rho_{\text{RCu}}} \frac{N}{\ell_{\text{sol}}\ell_{\text{Cu}}^2} = \frac{\mu_0 V_0 m_{\text{Cu}}\rho_{\text{Cu}}}{\rho_{\text{RCu}}} \frac{\frac{\ell_{\text{Cu}}}{2\pi r_{\text{sol}}}}{\ell_{\text{sol}}\ell_{\text{Cu}}^2} = \frac{\mu_0 V_0 m_{\text{Cu}}\rho_{\text{Cu}}}{2\pi\rho_{\text{RCu}}} \frac{1}{\ell_{\text{sol}} r_{\text{sol}} \ell_{\text{Cu}}}$$

The first factor in the expression for B is made of constants, so we have $B \propto \dfrac{1}{\ell_{\text{sol}} r_{\text{sol}} \ell_{\text{Cu}}}$. Thus we want the wire to be $\boxed{\text{short and fat}}$. Also the radius of the solenoid should be small and the length of the solenoid small.

71. The magnetic field inside the smaller solenoid will equal the sum of the fields from both solenoids. The field outside the inner solenoid will equal the field produced by the outer solenoid only. We set the sum of the two fields given by Eq. 28-4 equal to $-\frac{1}{2}$ times the field of the outer solenoid and solve for the ratio of the turn density.

$$\mu_0(-I)n_a + \mu_0 I n_b = -\tfrac{1}{2}(\mu_0 I n_b) \quad \rightarrow \quad \boxed{\frac{n_b}{n_a} = \frac{2}{3}}$$

72. Take the origin of coordinates to be at the center of the semicircle.The magnetic field at the center of the semicircle is the vector sum of the magnetic fields from each of the two long wires and from the semicircle. By the right-hand-rule each of these fields point into the page, so we can sum the magnitudes of the fields. The magnetic field for each of the long segments is obtained by integrating Eq. 28-5 over the straight segment.

$$\vec{\mathbf{B}}_{\text{straight}} = \int \frac{\mu_0 I}{4\pi} \frac{d\vec{\ell}\times\hat{R}}{R^2} = \int \frac{\mu_0 I}{4\pi} \frac{d\vec{\ell}\times\vec{\mathbf{R}}}{R^3} = \frac{\mu_0 I}{4\pi}\int_{-\infty}^{0} \frac{dx\,\hat{\mathbf{i}}\times\left(-x\hat{\mathbf{i}} - r\hat{\mathbf{j}}\right)}{\left(x^2+r^2\right)^{3/2}} = -\frac{\mu_0 I r}{4\pi}\hat{\mathbf{k}}\int_{-\infty}^{0} \frac{dx}{\left(x^2+r^2\right)^{3/2}}$$

$$= -\frac{\mu_0 I r}{4\pi}\hat{\mathbf{k}} \frac{x}{r^2\left(x^2+r^2\right)^{1/2}}\bigg|_{-\infty}^{0} = -\frac{\mu_0 I}{4\pi r}\hat{\mathbf{k}}$$

The magnetic field for the curved segment is obtained by integrating Eq. 28-5 over the semicircle.

$$\vec{\mathbf{B}}_{\text{curve}} = \frac{\mu_0 I}{4\pi}\int_0^{\pi r} \frac{d\vec{\ell}\times\hat{r}}{r^2} = -\frac{\mu_0 I}{4\pi r^2}\hat{\mathbf{k}}\int_0^{\pi r} ds = -\frac{\mu_0 I}{4r}\hat{\mathbf{k}}$$

$$\vec{\mathbf{B}} = 2\vec{\mathbf{B}}_{\text{straight}} + \vec{\mathbf{B}}_{\text{curve}} = -2\frac{\mu_0 I}{4\pi r}\hat{\mathbf{k}} - \frac{\mu_0 I}{4r}\hat{\mathbf{k}} = \boxed{-\frac{\mu_0 I}{4\pi r}(2+\pi)\hat{\mathbf{k}}}$$

73. (*a*) Set $x = 0$ at the midpoint on the axis between the two loops. Since the loops are a distance R apart, the center of one loop will be at $x = -\frac{1}{2}R$ and the center of the other at $x = \frac{1}{2}R$. The currents in the loops flow in opposite directions, so by the right-hand-rule the magnetic fields from the two wires will subtract from each other. The magnitude of each field can be obtained from Example 28-12.

$$B(x) = \frac{\mu_0 NIR^2}{2\left[R^2 + \left(\frac{1}{2}R - x\right)^2\right]^{3/2}} - \frac{\mu_0 NIR^2}{2\left[R^2 + \left(\frac{1}{2}R + x\right)^2\right]^{3/2}}$$

Factoring out $\frac{1}{8}R^3$ from each of the denominators yields the desired equation.

$$B(x) = \frac{4\mu_0 NI}{R\left[4 + \left(1 - 2x/R\right)^2\right]^{3/2}} - \frac{4\mu_0 NI}{R\left[4 + \left(1 + 2x/R\right)^2\right]^{3/2}}$$

$$= \boxed{\frac{4\mu_0 NI}{R}\left\{\left[4 + \left(1 - \frac{2x}{R}\right)^2\right]^{-3/2} - \left[4 + \left(1 + \frac{2x}{R}\right)^2\right]^{-3/2}\right\}}$$

(*b*) For small values of x, we can use the approximation $\left(1 \pm \frac{2x}{R}\right)^2 \approx 1 \pm \frac{4x}{R}$.

$$B(x) = \frac{4\mu_0 NI}{R}\left\{\left[4 + 1 - \frac{4x}{R}\right]^{-3/2} - \left[4 + 1 + \frac{4x}{R}\right]^{-3/2}\right\}$$

$$= \frac{4\mu_0 NI}{5R\sqrt{5}}\left\{\left[1 - \frac{4x}{5R}\right]^{-3/2} - \left[1 + \frac{4x}{5R}\right]^{-3/2}\right\}$$

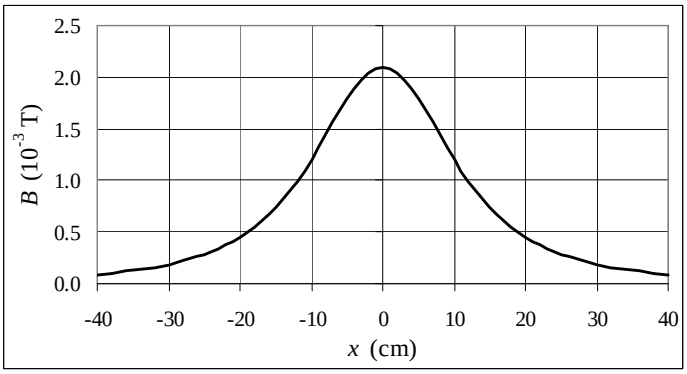
Again we can use the expansion for small deviations $\left(1 \pm \frac{4x}{5R}\right)^{-3/2} \approx 1 \mp \frac{6x}{5R}$

$$B(x) = \frac{4\mu_0 NI}{5R\sqrt{5}}\left[\left(1 + \frac{6x}{5R}\right) - \left(1 - \frac{6x}{5R}\right)\right] = \boxed{\frac{48\mu_0 NIx}{25R^2\sqrt{5}}}$$

This magnetic field has the expected linear dependence on x with a coefficient of $C = 48\mu_0 NI / \left(25R^2\sqrt{5}\right)$.

(*c*) Set C equal to 0.15 T/m and solve for the current.

$$I = \frac{25CR^2\sqrt{5}}{48\mu_0 N} = \frac{25\left(0.15\ \text{T/m}\right)\left(0.04\ \text{m}\right)^2\sqrt{5}}{48\left(4\pi \times 10^{-7}\ \text{T}\cdot\text{m/A}\right)\left(150\right)} = \boxed{1.5\ \text{A}}$$



74. We calculate the peak current using Eqs. 25-7 and 25-9. Then we use the peak current in Eq. 28-1 to calculate the maximum magnetic field.

$$I_{\max} = \sqrt{2}I_{\text{rms}} = \sqrt{2}\frac{P_{\text{avg}}}{V_{\text{rms}}} \quad \rightarrow \quad B_{\max} = \frac{\mu_0 I_{\max}}{2\pi r} = \frac{\sqrt{2}\mu_0}{2\pi r}\frac{P_{\text{avg}}}{V_{\text{rms}}}$$

$$= \frac{\sqrt{2}\left(4\pi \times 10^{-7}\ \text{T•m/A}\right)}{2\pi\left(12\ \text{m}\right)}\frac{\left(45 \times 10^6\ \text{W}\right)}{\left(15 \times 10^3\ \text{V}\right)} = \boxed{71\ \mu\text{T}}$$

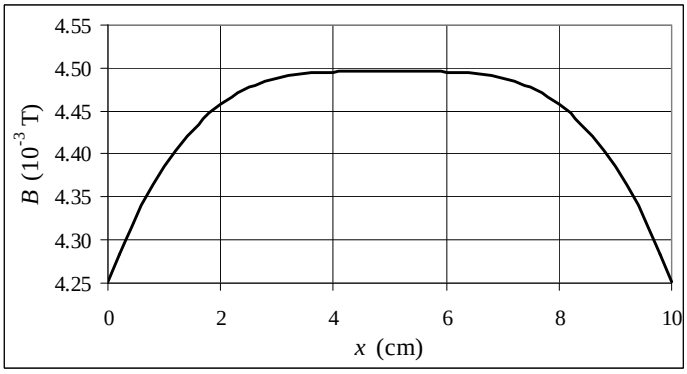
75. We use the results of Example 28-12 to calculate the magnetic field as a function of position. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH28.XLS," on tab "Problem 28.75."



$$B = \frac{N\mu_0 IR^2}{2\left(R^2 + x^2\right)^{3/2}} = \frac{(250)\left(4\pi \times 10^{-7}\,\text{T•m/A}\right)(2.0\,\text{A})(0.15\,\text{m})^2}{2\left[(0.15\,\text{m})^2 + x^2\right]^{3/2}} = \frac{7.0686 \times 10^{-6}\,\text{T•m}^3}{\left[(0.15\,\text{m})^2 + x^2\right]^{3/2}}.$$

76. (*a*) Use the results of Problem 61(a) to write the magnetic field.

$$B(x) = \frac{\mu_0 NIR^2}{2\left[R^2 + x^2\right]^{3/2}} + \frac{\mu_0 NIR^2}{2\left[R^2 + (x-R)^2\right]^{3/2}}$$

(*b*) See the graph. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH28.XLS," on tab "Problem 28.76b."

(*c*) Use the values from the spreadsheet to find the % difference.

$$\%\,\text{diff} = \frac{B(x = 6.0\,\text{cm}) - B(x = 5.0\,\text{cm})}{B(x = 5.0\,\text{cm})}(100) = \frac{4.49537\,\text{mT} - 4.49588\,\text{mT}}{4.49588\,\text{mT}}(100)$$

$$= \boxed{-1.1 \times 10^{-2}\%}$$

CHAPTER 29: Electromagnetic Induction and Faraday's Law

Responses to Questions

1. Using coils with many (N) turns increases the values of the quantities to be experimentally measured, because the induced emf and therefore the induced current are proportional to N.

2. Magnetic flux is a quantitative measure of the number of magnetic field lines passing through a given area. It depends not only on the field itself, but also on the area and on the angle between the field and the area.

3. Yes, the current is induced clockwise. No, there is no induced current if the magnet is steady, because there is no changing flux through the ring. Yes, the current is induced counterclockwise.

4. There is no induced current in the loop that is moving parallel to the wire because there is no change of magnetic flux through the loop. The induced current in the loop moving away from the wire is clockwise. The magnetic field through the loop due to the current is directed into the page, and the loop is moving such that its distance from the wire is increasing, resulting in a decrease in magnetic field strength and therefore a decrease in magnetic flux through the loop. By Lenz's law, a decreasing magnetic flux into the page results in a clockwise induced current.

5. Yes. The force is attractive. The induced clockwise current in the right loop will induce a counterclockwise current in the left loop which will slow the relative motion of the loops.

6. (*a*) Yes.
   (*b*) The current starts as soon as the battery is connected and current begins to flow in the first loop.
   (*c*) The induced current stops as soon as the current in the first loop has reached its steady value.
   (*d*) The induced current in the second loop will be counterclockwise, in order to oppose the change.
   (*e*) While there is an induced current, there will be a force between the two loops.
   (*f*) The force will be repulsive, since the currents are in opposite directions.

7. Yes, a current will be induced in the second coil. It will start when the battery is disconnected from the first coil and stop when the current falls to zero in the first coil. The current in the second loop will be clockwise.

8. Counterclockwise. If the area of the loop decreases, the flux through the loop (directed out of the page) decreases. By Lenz's law, the resulting induced current will be counterclockwise to oppose the change. Another way to approach this question is to use the right-hand rule. As the bar moves to the left, the negative electrons in the bar will experience a force down, which results in a counterclockwise current.

9. (*a*) The current through R_A will be to the right. The field due to the current in coil B will be to the left. As coil B is moved toward coil A, the flux through A will increase, so the induced field in coil A will be to the right, to oppose the change. This field corresponds to an induced current flowing from left to right in R_A.
   (*b*) The current through R_A will be to the left. When coil B is moved away from coil A, the flux through coil A will decrease, so the induced field will be to the left, to oppose the change. This field corresponds to an induced current flowing from right to left in R_A.
   (*c*) If R_B is increased, the current in the circuit will decrease, decreasing the flux through coil A, resulting in a current through R_A to the left.

10. The shielding prevents external fields from inducing a current which would cause a false signal in the inner signal wire.

11. The currents in the two wires will be 180° out of phase. If they are very close together, or wrapped around each other, then the magnetic fields created by the currents in the wires will very nearly cancel each other.

12. The straight wire will fall faster. Since the magnetic field is non-uniform, the flux through the loop will change as the loop falls, inducing a current which will oppose the change and therefore resist the downward motion. Eddy currents will also be induced in the straight wire, but they will be much smaller since the straight wire does not form a closed loop.

13. (*a*) Yes. If a rapidly changing magnetic field exists outside, then currents will be induced in the metal sheet. These currents will create magnetic fields which will partially cancel the external fields.
(*b*) Yes. Since the metal sheet is permeable, it will partially shield the interior from the exterior static magnetic field; some of the magnetic field lines will travel through the metal sheet.
(*c*) The superconducting sheet will shield the interior from magnetic fields.

14. Each of the devices mentioned has a different operating current and voltage, and each needs its own transformer with its own ratio of primary to secondary turns designed to convert normal household current and voltage into the required current and voltage. If the devices were designed to operate with the same current and voltage, they could all run on identical transformers.

15. You could hook the transformer up to a known ac voltage source. The ratio of the output voltage to the input voltage will give the ratio of turns on the two coils. If you pair up the leads incorrectly (one lead from each coil, rather than both leads from the same coil), there will be no output voltage. Alternatively, you could attach an ohmmeter to two of the leads. The resistance will be infinite if you have one lead from each pair, and nearly zero if you have both leads from the same pair.

16. Higher voltages are inherently more dangerous because of the increased risk of establishing large currents and large electromagnetic fields. The large potential differences between the wires and the ground could cause arcing and short circuits, leading to accidental electrocutions. In addition, higher-voltage power lines will have higher electromagnetic fields associated with them than lower-voltage power lines. Biological effects of exposure to high electromagnetic fields are not well understood, but there is evidence of increased health risks to people who live close to high voltage power lines.

17. When the transformer is connected to the 120-V dc source no back emf is generated, as would happen with an ac source. Therefore, the current in the transformer connected to the dc source will be very large. Because transformers generally are made with fine, low resistance wires, the large current could cause the wires to overheat, melt the insulation, and burn out.

18. A motor uses electric energy to create mechanical energy. When a large electric motor is running, the current in the motor's coil creates a back emf. When the motor is first turned on, the back emf is small, allowing the motor to draw maximum current. The back emf has a maximum value when the motor is running at full speed, reducing the amount of current required to run the motor. As the current flow in the motor's coil stabilizes, the motor will operate at its lower, normal current. The lights will dim briefly when the refrigerator motor starts due to the increased current load on the house circuit. Electric heaters operate by sending a large current through a large resistance, generating heat. When an electric heater is turned on, the current will increase quickly to its

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

maximum value (no coil, so no back emf) and will stay at its maximum value as long as the heater is on. Therefore, the lights will stay dim as long as the heater is on.

19. At the moment shown in Figure 29-15, the armature is rotating clockwise and so the current in length *b* of the wire loop on the armature is directed outward. (Use the right-hand rule: the field is north to south and the wire is moving with a component downward, therefore force on positive charge carriers is out.) This current is increasing, because as the wire moves down, the downward component of the velocity increases. As the current increases, the flux through the loop also increases, and therefore there is an induced emf to oppose this change. The induced emf opposes the current flowing in section *b* of the wire, and therefore creates a counter-torque.

20. Eddy currents exist in any conducting material, so eddy current brakes could work with wheels made of copper or aluminum.

21. The nonferrous materials are not magnetic but they are conducting. As they pass by the permanent magnets, eddy currents will be induced in them. The eddy currents provide a "braking" mechanism which will cause the metallic materials to slide more slowly down the incline than the nonmetallic materials. The nonmetallic materials will reach the bottom with larger speeds. The nonmetallic materials can therefore be separated from the metallic, nonferrous materials by placing bins at different distances from the bottom of the incline. The closest bin will catch the metallic materials, since their projectile velocities off the end of the incline will be small. The bin for the nonmetallic materials should be placed farther away to catch the higher-velocity projectiles.

22. The slots in the metal bar prevent the formation of large eddy currents, which would slow the bar's fall through the region of magnetic field.

23. As the aluminum sheet is moved through the magnetic field, eddy currents are created in the sheet. The magnetic force on these induced currents opposes the motion. Thus it requires some force to pull the sheet out. (See Figure 29-21.)

24. As the bar magnet falls, it sets up eddy currents in the metal tube which will interact with the magnet and slow its fall. The magnet will reach terminal velocity (due to the interactions with the magnetic dipoles set up by the eddy currents, not air resistance) when the weight of the magnet is balanced by the upward force from the eddy currents.

25. As the bar moves in the magnetic field, induced eddy currents are created in the bar. The magnetic field exerts a force on these currents that opposes the motion of the bar. (See Figure 29-21.)

26. Although in principle you could use a loudspeaker in reverse as a microphone, it would probably not work in actual practice. The membrane of the microphone is very lightweight and sensitive to the sound waves produced by your voice. The cardboard cone of a loudspeaker is much stiffer and would significantly dampen the vibrations so that the frequency of the impinging sound waves would not be translated into an induced emf with the same frequency.

Solutions to Problems

1. The average induced emf is given by Eq. 29-2b.

$$\mathscr{E} = -N\frac{d\Phi_B}{dt} = -N\frac{\Delta\Phi_B}{\Delta t} = -2\frac{38\,\text{Wb} - (-58\,\text{Wb})}{0.42\,\text{s}} = \boxed{-460\,\text{V}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2. As the magnet is pushed into the coil, the magnetic flux increases to the right. To oppose this increase, flux produced by the induced current must be to the left, so the induced current in the resistor will be from right to left.

3. As the coil is pushed into the field, the magnetic flux through the coil increases into the page. To oppose this increase, the flux produced by the induced current must be out of the page, so the induced current is counterclockwise.

4. The flux changes because the loop rotates. The angle between the field and the normal to the loop changes from 0^o to 90^o. The average induced emf is given by the "difference" version of Eq. 29-2b.

$$\mathscr{E}_{\text{avg}} = -\frac{\Delta\Phi_B}{\Delta t} = -\frac{AB\Delta\cos\theta}{\Delta t} = -\frac{\pi(0.110\,\text{m})^2\,1.5\,\text{T}\left(\cos 90^o - \cos 0^o\right)}{0.20\,\text{s}}$$

$$= -\frac{\pi(0.110\,\text{m})^2\,1.5\,\text{T}(0-1)}{0.20\,\text{s}} = \boxed{0.29\,\text{V}}$$

5. Use Eq. 29-2a to calculate the emf. Setting the flux equal to the magnetic field multiplied by the area of the loop, $A = \pi r^2$, and the emf equal to zero, we can solve for the rate of change in the coil radius.

$$\mathscr{E} = -\frac{d\Phi_B}{dt} = -\frac{d}{dt}\left(B\pi r^2\right) = -\frac{dB}{dt}\pi r^2 - 2\pi Br\frac{dr}{dt} = 0$$

$$\frac{dr}{dt} = -\frac{dB}{dt}\frac{r}{2B} = -(-0.010\ \text{T/s})\frac{0.12\ \text{m}}{2(0.500\ \text{T})} = 0.0012\ \text{m/s} = \boxed{1.2\ \text{mm/s}}$$

6. We choose up as the positive direction. The average induced emf is given by the "difference" version of Eq. 29-2a.

$$\mathscr{E} = -\frac{\Delta\Phi_B}{\Delta t} = -\frac{A\Delta B}{\Delta t} = -\frac{\pi(0.054\,\text{m})^2\left(-0.25\,\text{T} - 0.68\,\text{T}\right)}{0.16\,\text{s}} = \boxed{5.3\times10^{-2}\,\text{V}}$$

7. (*a*) When the plane of the loop is perpendicular to the field lines, the flux is given by the maximum of Eq. 29-1a.

$$\Phi_B = BA = B\pi r^2 = (0.50\,\text{T})\,\pi\,(0.080\,\text{m})^2 = \boxed{1.0\times10^{-2}\,\text{Wb}}$$

(*b*) The angle is $\theta = \boxed{55^o}$

(*c*) Use Eq. 29-1a.

$$\Phi_B = BA\cos\theta = B\pi r^2 = (0.50\,\text{T})\,\pi\,(0.080\,\text{m})^2\cos 55^o = \boxed{5.8\times10^{-3}\,\text{Wb}}$$

8. (*a*) As the resistance is increased, the current in the outer loop will decrease. Thus the flux through the inner loop, which is out of the page, will decrease. To oppose this decrease, the induced current in the inner loop will produce a flux out of the page, so the direction of the induced current will be counterclockwise.

(*b*) If the small loop is placed to the left, the flux through the small loop will be into the page and will decrease. To oppose this decrease, the induced current in the inner loop will produce a flux into the page, so the direction of the induced current will be clockwise.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9. As the solenoid is pulled away from the loop, the magnetic flux to the right through the loop decreases. To oppose this decrease, the flux produced by the induced current must be to the right, so the induced current is counterclockwise as viewed from the right end of the solenoid.

10. (*a*) The average induced emf is given by the "difference" version of Eq. 29-2b.

$$\mathscr{E} = -\frac{\Delta\Phi_B}{\Delta t} = -\frac{A\Delta B}{\Delta t} = -\frac{\pi(0.040\,\text{m})^2(-0.45\,\text{T} - 0.52\,\text{T})}{0.18\,\text{s}} = \boxed{2.7\times10^{-2}\,\text{V}}$$

(*b*) The positive result for the induced emf means the induced field is away from the observer, so the induced current is clockwise.

11. (*a*) The magnetic flux through the loop is into the paper and decreasing, because the area is decreasing. To oppose this decrease, the induced current in the loop will produce a flux into the paper, so the direction of the induced current will be clockwise.

(*b*) The average induced emf is given by the "difference" version of Eq. 29-2b.

$$\left|\mathscr{E}_{\text{avg}}\right| = \frac{\Delta\Phi_B}{\Delta t} = \frac{B|\Delta A|}{\Delta t} = \frac{(0.75\,\text{T})\pi\left[(0.100\,\text{m})^2 - (0.030\,\text{m})^2\right]}{0.50\,\text{s}}$$

$$= 4.288\times10^{-2}\,\text{V} \approx \boxed{4.3\times10^{-2}\,\text{V}}$$

(*c*) We find the average induced current from Ohm's law.

$$I = \frac{\mathscr{E}}{R} = \frac{4.288\times10^{-2}\,\text{V}}{2.5\,\Omega} = \boxed{1.7\times10^{-2}\,\text{A}}$$

12. As the loop is pulled from the field, the flux through the loop decreases, causing an induced EMF whose magnitude is given by Eq. 29-3, $\mathscr{E} = B\ell v$. Because the inward flux is decreasing, the induced flux will be into the page, so the induced current is clockwise, given by $I = \mathscr{E}/R$. Because this current in the left-hand side of the loop is in a downward magnetic field, there will be a magnetic force to the left. To keep the rod moving, there must be an equal external force to the right, given by $F = I\ell B$.

$$F = I\ell B = \frac{\mathscr{E}}{R}\ell B = \frac{B\ell v}{R}\ell B = \frac{B^2\ell^2 v}{R} = \frac{(0.650\,\text{T})^2(0.350\,\text{m})^2(3.40\,\text{m/s})}{0.280\,\Omega} = \boxed{0.628\,\text{N}}$$

13. (*a*) Use Eq. 29-2a to calculate the emf induced in the ring, where the flux is the magnetic field multiplied by the area of the ring. Then using Eq. 25-7, calculate the average power dissipated in the ring as it is moved away. The thermal energy is the average power times the time.

$$\mathscr{E} = -\frac{\Delta\Phi_B}{\Delta t} = -\frac{\Delta BA}{\Delta t} = -\frac{\Delta B\left(\frac{1}{4}\pi d^2\right)}{\Delta t}$$

$$Q = P\Delta t = \left(\frac{\mathscr{E}^2}{R}\right)\Delta t = \left(\frac{\Delta B\left(\frac{1}{4}\pi d^2\right)}{\Delta t}\right)^2\left(\frac{\Delta t}{R}\right) = \frac{(\Delta B)^2\pi^2 d^4}{16R\Delta t}$$

$$= \frac{(0.80\,\text{T})^2\pi^2(0.015\,\text{m})^4}{16\left(55\times10^{-6}\,\Omega\right)\left(45\times10^{-3}\,\text{s}\right)} = 8.075\times10^{-3}\,\text{J} \approx \boxed{8.1\,\text{mJ}}$$

(*b*) The temperature change is calculated from the thermal energy using Eq. 19-2.

$$\Delta T = \frac{Q}{mc} = \frac{8.075\times10^{-3}\,\text{J}}{\left(15\times10^{-3}\,\text{kg}\right)\left(129\,\text{J/kg}\bullet°\text{C}\right)} = \boxed{4.2\times10^{-3}\,\text{C}°}$$

14. The average emf induced in the short coil is given by the "difference" version of Eq. 29-2b. N is the number of loops in the short coil, and the flux change is measured over the area of the short coil. The magnetic flux comes from the field created by the solenoid. The field in a solenoid is given by Eq. 28-4, $B = \mu_0 I N_{\text{solenoid}} / \ell_{\text{solenoid}}$, and the changing current in the solenoid causes the field to change.

$$\left|\mathscr{E}\right| = \frac{N_{\text{short}} A_{\text{short}} \Delta B}{\Delta t} = \frac{N_{\text{short}} A_{\text{short}} \Delta\left(\dfrac{\mu_0 I N_{\text{solenoid}}}{\ell_{\text{solenoid}}}\right)}{\Delta t} = \frac{\mu_0 N_{\text{short}} N_{\text{solenoid}} A_{\text{short}}}{\ell_{\text{solenoid}}} \frac{\Delta I}{\Delta t}$$

$$= \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(15)(420)\pi\left(0.0125\,\text{m}\right)^2}{\left(0.25\,\text{m}\right)} \frac{\left(5.0\,\text{A}\right)}{\left(0.60\,\text{s}\right)} = \boxed{1.3\times10^{-4}\,\text{V}}$$

15. (*a*) There is an emf induced in the coil since the flux through the coil changes. The current in the coil is the induced emf divided by the resistance of the coil. The resistance of the coil is found from Eq. 25-3.

$$\left|\mathscr{E}\right| = NA_{\text{coil}} \frac{dB}{dt} \qquad R = \frac{\rho\ell}{A_{\text{wire}}}$$

$$I = \frac{\mathscr{E}}{R} = \frac{NA_{\text{coil}} \dfrac{dB}{dt}}{\dfrac{\rho\ell}{A_{\text{wire}}}} = \frac{NA_{\text{coil}} A_{\text{wire}}}{\rho\ell} \frac{dB}{dt}$$

$$= \frac{28\left[\pi\left(0.110\,\text{m}\right)^2\right]\left[\pi\left(1.3\times10^{-3}\,\text{m}\right)^2\right]\left(8.65\times10^{-3}\,\text{T/s}\right)}{\left(1.68\times10^{-8}\,\Omega\text{•m}\right)28\left(2\pi\right)\left(0.110\,\text{m}\right)} = 0.1504\,\text{A} \approx \boxed{0.15\,\text{A}}$$

(*b*) The rate at which thermal energy is produced in the wire is the power dissipated in the wire.

$$P = I^2 R = I^2 \frac{\rho\ell}{A_{\text{wire}}} = \left(0.1504\,\text{A}\right)^2 \frac{\left(1.68\times10^{-8}\,\Omega\text{•m}\right)28\left(2\pi\right)\left(0.11\right)}{\pi\left(1.3\times10^{-3}\,\text{m}\right)^2} = \boxed{1.4\times10^{-3}\,\text{W}}$$

16. The sinusoidal varying current in the power line creates a sinusoidal varying magnetic field encircling the power line, given by Eq. 28-1. Using Eq. 29-1b we integrate this field over the area of the rectangle to determine the flux through it. Differentiating the flux as in Eq. 29-2b gives the emf around the rectangle. Finally, by setting the maximum emf equal to 170 V we can solve for the necessary length of the rectangle.

$$B(t) = \frac{\mu_0 I_0}{2\pi r}\cos\left(2\pi ft\right)\ ;$$

$$\Phi_B(t) = \int B\,dA = \int_{5.0\text{ m}}^{7.0\text{ m}} \frac{\mu_0 I_0}{2\pi r}\cos\left(2\pi ft\right)\ell\,dr = \frac{\mu_0 I_0}{2\pi}\ell\cos\left(2\pi ft\right)\int_{5.0\text{ m}}^{7.0\text{ m}} \frac{dr}{r} = \frac{\mu_0 I_0}{2\pi}\ln\left(1.4\right)\ell\cos\left(2\pi ft\right)$$

$$\mathscr{E} = -N\frac{d\Phi_B}{dt} = -\frac{N\mu_0 I_0}{2\pi}\ln\left(1.4\right)\ell\left[\frac{d}{dt}\cos\left(2\pi ft\right)\right] = N\mu_0 I_0 f\ \ln\left(1.4\right)\ell\sin\left(2\pi ft\right)\ ;$$

$$\mathscr{E}_0 = N\mu_0 I_0 f\ \ln\left(1.4\right)\ell\ \rightarrow$$

$$\ell = \frac{\mathscr{E}_0}{N\mu_0 I_0 f\ \ln\left(1.4\right)} = \frac{170\,\text{V}}{10\left(4\pi\times10^{-7}\,\text{T•m/A}\right)\left(55{,}000\,\text{A}\right)\left(60\,\text{Hz}\right)\ln\left(1.4\right)} = \boxed{12\,\text{m}}$$

This is unethical because the current in the rectangle creates a back emf in the initial wire. This results in a power loss to the electric company, just as if the wire had been physically connected to the line.

17. The charge that passes a given point is the current times the elapsed time, $Q = I\Delta t$. The current will be the emf divided by the resistance, $I = \dfrac{\mathscr{E}}{R}$. The resistance is given by Eq. 25-3, $R = \dfrac{\rho\ell}{A_{\text{wire}}}$, and the emf is given by the "difference" version of Eq. 29-2a. Combine these equations to find the charge during the operation.

$$|\mathscr{E}| = \frac{\Delta\Phi_B}{\Delta t} = \frac{A_{\text{loop}}|\Delta B|}{\Delta t} \;;\; R = \frac{\rho\ell}{A_{\text{wire}}} \;;\; I = \frac{\mathscr{E}}{R} = \frac{\dfrac{A_{\text{loop}}|\Delta B|}{\Delta t}}{\dfrac{\rho\ell}{A_{\text{wire}}}} = \frac{A_{\text{loop}}A_{\text{wire}}|\Delta B|}{\rho\ell\Delta t}$$

$$Q = I\Delta t = \frac{A_{\text{loop}}A_{\text{wire}}|\Delta B|}{\rho\ell} = \frac{\pi r_{\text{loop}}^2 \pi r_{\text{wire}}^2 |\Delta B|}{\rho(2\pi)r_{\text{loop}}} = \frac{r_{\text{loop}}\pi r_{\text{wire}}^2|\Delta B|}{2\rho}$$

$$= \frac{(0.091\,\text{m})\pi\left(1.175\times10^{-3}\,\text{m}\right)^2(0.750\,\text{T})}{2\left(1.68\times10^{-8}\,\Omega\bullet\text{m}\right)} = \boxed{8.81\,\text{C}}$$

18. (*a*) Use Eq. 29-2b to calculate the emf.

$$\mathscr{E} = -N\frac{d\Phi_B}{dt} = (-75)\frac{d}{dt}\left[\left(8.8t - 0.51t^3\right)\times10^{-2}\,\text{T}\bullet\text{m}^2\right] = \left(-6.6 + 1.1475t^2\right)\text{V}$$

$$\approx \boxed{\left(-6.6 + 1.1t^2\right)\text{V}}$$

(*b*) Evaluate at the specific times.

$$\mathscr{E}(t = 1.0\,\text{s}) = \left(-6.6 + 1.1475(1.0)^2\right)\text{V} = \boxed{-5.5\,\text{V}}$$

$$\mathscr{E}(t = 4.0\,\text{s}) = \left(-6.6 + 1.1475(4.0)^2\right)\text{V} = \boxed{12\,\text{V}}$$

19. The energy dissipated in the process is the power dissipated by the resistor, times the elapsed time that the current flows. The average induced emf is given by the "difference" version of Eq. 29-2a.

$$\mathscr{E} = -\frac{\Delta\Phi_B}{\Delta t} \;;\; P = \frac{\mathscr{E}^2}{R} \;;$$

$$E = P\Delta t = \frac{\mathscr{E}^2}{R}\Delta t = \left(\frac{\Delta\Phi_B}{\Delta t}\right)^2\frac{\Delta t}{R} = \frac{A^2(\Delta B)^2}{R\Delta t} = \frac{\left[\pi(0.125\,\text{m})^2\right]^2(0.40\,\text{T})^2}{(150\,\Omega)(0.12\,\text{s})} = \boxed{2.1\times10^{-5}\,\text{J}}$$

20. The induced emf is given by Eq. 29-2a. Since the field is uniform and is perpendicular to the area, the flux is simply the field times the area.

$$\mathscr{E} = -\frac{d\Phi_B}{dt} = -B\frac{dA}{dt} = -(0.28\,\text{T})\left(-3.50\times10^{-2}\,\text{m}^2/\text{s}\right) = \boxed{9.8\,\text{mV}}$$

Since the area changes at a constant rate, and the area has not shrunk to 0 at t = 2.00 s, the emf is the same for both times.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21. The induced emf is given by Eq. 29-2a. Since the field is uniform and is perpendicular to the area, the flux is simply the field times the area of a circle. We calculate the initial radius from the initial area. To calculate the radius after one second we add the change in radius to the initial radius.

$$\mathscr{E}(t) = \frac{d\Phi_B}{dt} = B\frac{d\left(\pi r^2\right)}{dt} = 2\pi Br\frac{dr}{dt} \qquad A_0 = \pi r_0^2 \rightarrow r_0 = \sqrt{\frac{A_0}{\pi}}$$

$$\mathscr{E}(0) = 2\pi\left(0.28\,\text{T}\right)\sqrt{\frac{0.285\,\text{m}^2}{\pi}}\left(0.043\,\text{m/s}\right) = \boxed{23\,\text{mV}}$$

$$\mathscr{E}(1.00\,\text{s}) = 2\pi\left(0.28\,\text{T}\right)\left[\sqrt{\frac{0.285\,\text{m}^2}{\pi}} + \left(0.043\,\text{m/s}\right)\left(1.00\,\text{s}\right)\right]\left(0.043\,\text{m/s}\right) = \boxed{26\,\text{mV}}$$

22. The magnetic field inside the solenoid is given by Eq. 28-4, $B = \mu_0 nI$. Use Eq. 29-2a to calculate the induced emf. The flux causing the emf is the flux through the small loop.

$$\mathscr{E} = -\frac{d\Phi_B}{dt} = -A_1\frac{dB_{\text{solenoid}}}{dt} = -A_1\mu_0 n\frac{dI}{dt} = -A_1\mu_0 n\left(-\omega I_0\sin\omega t\right) = \boxed{A_1\mu_0 n\omega I_0\sin\omega t}$$

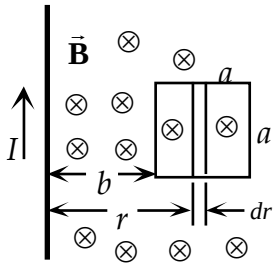
23. (*a*) If the magnetic field is parallel to the plane of the loop, no magnetic flux passes through the loop at any time. Therefore, the emf and the current in the loop are zero.

(*b*) When the magnetic field is perpendicular to the plane of the loop, we differentiate Eq. 29-1a with respect to time to obtain the emf in the loop. Then we divide the emf by the resistance to calculate the current in the loop.

$$I = \frac{\mathscr{E}}{R} = \frac{1}{R}\left(-\frac{d\Phi_B}{dt}\right) = -\frac{1}{R}\frac{d}{dt}\left[\left(\alpha t\right)\left(A_0 + \beta t\right)\right] = -\frac{\alpha}{R}\left[A_0 + 2\beta t\right]$$

$$= -\frac{\left(0.60\text{ T/s}\right)\left[\left(0.50\text{ m}^2\right) + 2\left(0.70\text{ m}^2\text{/s}\right)\left(2.0\text{ s}\right)\right]}{2.0\ \Omega} = -0.99\text{ A}$$

Since the magnetic field is pointing down into the page, the downward flux is increasing. The current then flows in a direction to create an upward flux. The resulting current is then 0.99 A in the counterclockwise direction.



24. The magnetic field across the primary coil is constant and is that of a solenoid (Eq. 28-4). We multiply this magnetic field by the area of the secondary coil to calculate the flux through the secondary coil. Then using Eq. 29-2b we differentiate the flux to calculate the induced emf.

$$\Phi_B = BA = \mu_0 n_p I_0\sin\left(2\pi ft\right)\left(\pi d^2/4\right)$$

$$\mathscr{E}_2 = N\frac{d\Phi_B}{dt} = N\mu_0 n_p I_0\left(\pi d^2/4\right)\left[\frac{d}{dt}\sin\left(2\pi ft\right)\right] = \boxed{-\tfrac{1}{2}\pi^2 d^2 fN\mu_0 n_p I_0\cos\left(2\pi ft\right)}$$

25. (*a*) The magnetic field a distance *r* from the wire is perpendicular to the wire and given by Eq. 28-1. Integrating this magnetic field over the area of the loop gives the flux through the loop.

$$\Phi_B = \int BdA = \int_b^{b+a}\frac{\mu_0 I}{2\pi r}a\,dr = \boxed{\frac{\mu_0 Ia}{2\pi}\ln\left(1+\frac{a}{b}\right)}$$

(*b*) Since the loop is being pulled away, $v = \frac{db}{dt}$. Differentiate the magnetic flux with respect to time to calculate the emf in the loop.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\mathscr{E} = -\frac{d\Phi_B}{dt} = -\frac{d}{dt}\left[\frac{\mu_0 Ia}{2\pi}\ln\left(1+\frac{a}{b}\right)\right] = -\frac{\mu_0 Ia}{2\pi}\frac{d}{db}\left[\ln\left(1+\frac{a}{b}\right)\right]\frac{db}{dt} = \boxed{\frac{\mu_0 Ia^2 v}{2\pi b(b+a)}}$$

Note that this is the emf at the instant the loop is a distance *b* from the wire. The value of *b* is changing with time.

(*c*) Since the magnetic field at the loop points into the page, and the flux is decreasing, the induced current will create a downward magnetic field inside the loop. The current in the loop then flows clockwise.

(*d*) The power dissipated in the loop as it is pulled away is related to the emf and resistance by Eq. 25-7b. This power is provided by the force pulling the loop away. We calculate this force from the power using Eq. 8-21. As in part (*b*), the value of *b* is changing with time.

$$F = \frac{P}{v} = \frac{\mathscr{E}^2}{Rv} = \boxed{\frac{\mu_0^2 I^2 a^4 v}{4\pi^2 R b^2 (b+a)^2}}$$

26. From Problem 25, the flux through the loop is given by $\Phi_B = \dfrac{\mu_0 Ia}{2\pi}\ln\left(1+\dfrac{a}{b}\right)$. The emf is found from Eq. 29-2a.

$$\mathscr{E} = -\frac{d\Phi_B}{dt} = -\frac{d}{dt}\left[\frac{\mu_0 Ia}{2\pi}\ln\left(1+\frac{a}{b}\right)\right] = -\frac{\mu_0 a}{2\pi}\ln\left(1+\frac{a}{b}\right)\frac{dI}{dt}$$

$$= -\frac{\left(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}\right)(0.120\ \text{m})}{2\pi}\ln\left(1+\frac{12.0}{15.0}\right)(15.0\ \text{A})(2500\ \text{rad/s})\cos(2500t)$$

$$= \boxed{\left(5.3\times10^{-4}\ \text{V}\right)\cos(2500t)}$$

27. The velocity is found from Eq. 29-3.

$$\mathscr{E} = B\ell v \quad\rightarrow\quad v = \frac{\mathscr{E}}{B\ell} = \frac{0.12\ \text{V}}{(0.90\ \text{T})(0.132\ \text{m})} = \boxed{1.0\ \text{m/s}}$$

28. Because the velocity is perpendicular to the magnetic field and the rod, we find the induced emf from Eq. 29-3.

$$\mathscr{E} = B\ell v = (0.800\ \text{T})(0.120\ \text{m})(0.150\ \text{m/s}) = \boxed{1.44\times10^{-2}\ \text{V}}$$

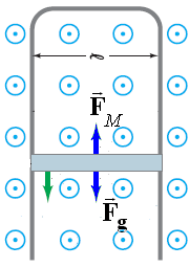
29. (*a*) Because the velocity is perpendicular to the magnetic field and the rod, we find the induced emf from Eq. 29-3.

$$\mathscr{E} = B\ell v = (0.35\ \text{T})(0.250\ \text{m})(1.3\ \text{m/s}) = 0.1138\ \text{V} \approx \boxed{0.11\ \text{V}}$$

(*b*) Find the induced current from Ohm's law, using the **total** resistance.

$$I = \frac{\mathscr{E}}{R} = \frac{0.1138\ \text{V}}{25.0\ \Omega + 2.5\ \Omega} = 4.138\times10^{-3}\ \text{A} \approx \boxed{4.1\ \text{mA}}$$

(*c*) The induced current in the rod will be down. Because this current is in an upward magnetic field, there will be a magnetic force to the left. To keep the rod moving, there must be an equal external force to the right, given by Eq. 27-1.



$$F = I\ell B = \left(4.138\times10^{-3}\ \text{A}\right)(0.250\ \text{m})(0.35\ \text{T}) = 3.621\times10^{-4}\ \text{N} \approx \boxed{0.36\ \text{mN}}$$

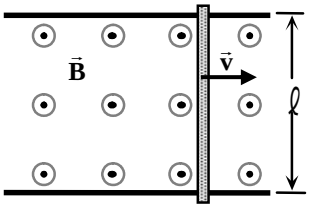
30. The emf is given by Eq. 29-3 as $\mathscr{E} = B\ell v$. The resistance of the conductor is given by Eq. 25-3. The length in Eq. 25-3 is the length of resistive material. Since the movable rod starts at the bottom of the U at time $t = 0$, in a time t it will have moved a distance vt.

$$I = \frac{\mathscr{E}}{R} = \frac{B\ell v}{\frac{\rho L}{A}} = \frac{B\ell v}{\frac{\rho(2vt+\ell)}{A}} = \boxed{\frac{B\ell vA}{\rho(2vt+\ell)}}$$

31. The rod will descend at its terminal velocity when the magnitudes of the magnetic force (found in Example 29-8) and the gravitational force are equal. We set these two forces equal and solve for the terminal velocity.



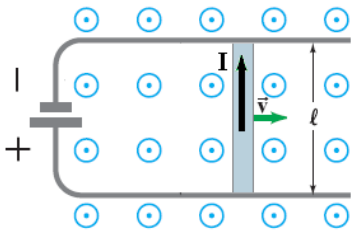
$$\frac{B^2\ell^2 v_t}{R} = mg \rightarrow$$

$$v_t = \frac{mgR}{B^2\ell^2} = \frac{(3.6\times10^{-3}\text{ kg})(9.80\text{ m/s}^2)(0.0013\ \Omega)}{(0.060\text{ T})^2(0.18\text{ m})^2} = \boxed{0.39\text{ m/s}}$$

32. Since the antenna is vertical, the maximum emf will occur when the car is traveling perpendicular to the horizontal component of the Earth's magnetic field. This occurs when the car is traveling in the east or west direction. We calculate the magnitude of the emf using Eq. 29-3, where B is the horizontal component of the Earth's magnetic field.

$$\mathscr{E} = B_x\ell v = (5.0\times10^{-5}\text{T}\cos45°)(0.750\text{m})(30.0\text{m/s}) = 8.0\times10^{-4}\text{V} = \boxed{0.80\text{mV}}$$

33. (*a*) As the rod moves through the magnetic field an emf will be built up across the rod, but no current can flow. Without the current, there is no force to oppose the motion of the rod, so yes, the rod travels at constant speed.



(*b*) We set the force on the moving rod, obtained in Example 29-8, equal to the mass times the acceleration of the rod. We then write the acceleration as the derivative of the velocity, and by separation of variables we integrate the velocity to obtain an equation for the velocity as a function of time.

$$F = ma = m\frac{dv}{dt} = -\frac{B^2\ell^2}{R}v \rightarrow \frac{dv}{v} = -\frac{B^2\ell^2}{mR}dt$$

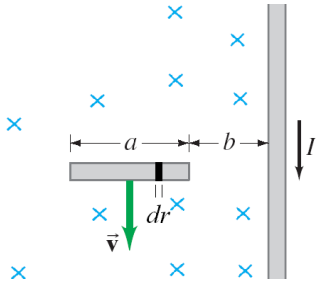
$$\int_{v_0}^{v}\frac{dv'}{v'} = -\frac{B^2\ell^2}{mR}\int_0^t dt' \rightarrow \ln\frac{v}{v_0} = -\frac{B^2\ell^2}{mR}t \rightarrow \boxed{v(t) = v_0 e^{-\frac{B^2\ell^2}{mR}t}}$$

The magnetic force is proportional to the velocity of the rod and opposes the motion. This results in an exponentially decreasing velocity.

34. (*a*) For a constant current, of polarity shown in the figure, the magnetic force will be constant, given by Eq. 27-2. Using Newton's second law we can integrate the acceleration to calculate the velocity as a function of time.

$$F = m\frac{dv}{dt} = I\ell B \rightarrow \int_0^v dv = \frac{I\ell B}{m}\int_0^t dt \rightarrow \boxed{v(t) = \frac{I\ell B}{m}t}$$

(*b*) For a constant emf, the current will vary with the speed of the rod, as motional emf opposes the motion of the rod. We again use Eq. 27-2 for the force on the rod, with the current given by Ohm's law, and the induced motional emf given by Eq 29-3. The current produced by the induced emf opposes the current produced by the battery.



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$F = m\frac{dv}{dt} = I\ell B = \left(\frac{\mathscr{E}_0 - B\ell v}{R}\right)\ell B \rightarrow \frac{dv}{\mathscr{E}_0 - B\ell v} = \frac{\ell B}{mR}dt \rightarrow \frac{dv}{v - \mathscr{E}_0/B\ell} = -\frac{B^2\ell^2}{mR}dt \rightarrow$$

$$\int_0^v \frac{dv}{v - \mathscr{E}_0/B\ell} = -\frac{B^2\ell^2}{mR}\int_0^t dt \rightarrow \ln\left(\frac{v - \mathscr{E}_0/B\ell}{-\mathscr{E}_0/B\ell}\right) = -\frac{B^2\ell^2}{mR}t \rightarrow \boxed{v(t) = \frac{\mathscr{E}_0}{B\ell}\left(1 - e^{-\frac{B^2\ell^2}{mR}t}\right)}$$

(*c*) With constant current, the acceleration is constant and so the velocity does not reach a terminal velocity. However, with constant emf, the increasing motional emf decreases the applied force. This results in a limiting, or terminal velocity of $\boxed{v_t = \mathscr{E}_0/B\ell}$.

35. (*a*) The magnetic field is perpendicular to the rod, with the magnetic field decreasing with distance from the rod, as in Eq. 28-1. The emf, $d\mathscr{E}$, across a short segment, *dr*, of the rod is given by the differential version of Eq. 29-3. Integrating this emf across the length of the wire gives the total emf.

$$d\mathscr{E} = Bvdr \rightarrow$$

$$\mathscr{E} = \int d\mathscr{E} = \int_b^{b+a} \frac{\mu_0 I}{2\pi r} v dr = \boxed{\frac{\mu_0 I v}{2\pi}\ln\left(\frac{b+a}{b}\right)}$$

This emf points toward the wire, as positive charges are attracted toward the current.

(*b*) The only change is the direction of the current, so the magnitude of the emf remains the same, but points away from the wire, since positive charges are repelled from the current.

36. From Eq. 29-4, the induced voltage is proportional to the angular speed. Thus their quotient is a constant.

$$\frac{\mathscr{E}_1}{\omega_1} = \frac{\mathscr{E}_2}{\omega_2} \rightarrow \mathscr{E}_2 = \mathscr{E}_1\frac{\omega_2}{\omega_1} = (12.4\,\text{V})\frac{1550\,\text{rpm}}{875\,\text{rpm}} = \boxed{22.0\,\text{V}}$$

37. We find the number of turns from Eq. 29-4. The factor multiplying the sine term is the peak output voltage.

$$\mathscr{E}_{\text{peak}} = NB\omega A \rightarrow N = \frac{\mathscr{E}_{\text{peak}}}{B\omega A} = \frac{24.0\,\text{V}}{(0.420\,\text{T})(2\pi\,\text{rad/rev})(60\,\text{rev/s})(0.0515\,\text{m})^2} = \boxed{57.2\text{ loops}}$$

38. From Eq. 29-4, the peak voltage is $\mathscr{E}_{\text{peak}} = NB\omega A$. Solve this for the rotation speed.

$$\mathscr{E}_{\text{peak}} = NB\omega A \rightarrow \omega = \frac{\mathscr{E}_{\text{peak}}}{NBA} = \frac{120\,\text{V}}{480(0.550\,\text{T})(0.220\,\text{m})^2} = 9.39\,\text{rad/s}$$

$$f = \frac{\omega}{2\pi} = \frac{9.39\,\text{rad/s}}{2\pi\,\text{rad/rev}} = \boxed{1.49\,\text{rev/s}}$$

39. From Eq. 29-4, the peak voltage is $\mathscr{E}_{\text{peak}} = NAB\omega$. The rms voltage is the peak voltage divided by $\sqrt{2}$, and so $V_{\text{rms}} = \mathscr{E}_{\text{peak}}/\sqrt{2} = NAB\omega/\sqrt{2}$.

40. Rms voltage is found from the peak induced emf. Peak induced emf is calculated from Eq. 29-4.

$$\mathscr{E}_{\text{peak}} = NB\omega A \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$V_{\text{rms}} = \frac{\mathscr{E}_{\text{peak}}}{\sqrt{2}} = \frac{NB\omega A}{\sqrt{2}} = \frac{(250)(0.45\,\text{T})(2\pi\,\text{rad/rev})(120\,\text{rev/s})\pi(0.050\,\text{m})^2}{\sqrt{2}}$$
$$= 471.1\,\text{V} \approx \boxed{470\,\text{V}}$$

To double the output voltage, you must double the rotation frequency to 240 rev/s.

41. From Eq. 29-4, the induced voltage (back emf) is proportional to the angular speed. Thus their quotient is a constant.

$$\frac{\mathscr{E}_1}{\omega_1} = \frac{\mathscr{E}_2}{\omega_2} \quad \rightarrow \quad \mathscr{E}_2 = \mathscr{E}_1 \frac{\omega_2}{\omega_1} = (72\,\text{V})\frac{2500\,\text{rpm}}{1200\,\text{rpm}} = \boxed{150\,\text{V}}$$

42. When the motor is running at full speed, the back emf opposes the applied emf, to give the net across the motor.

$$\mathscr{E}_{\text{applied}} - \mathscr{E}_{\text{back}} = IR \quad \rightarrow \quad \mathscr{E}_{\text{back}} = \mathscr{E}_{\text{applied}} - IR = 120\,\text{V} - (7.20\,\text{A})(3.05\,\Omega) = \boxed{98\,\text{V}}$$

43. The back emf is proportional to the rotation speed (Eq. 29-4). Thus if the motor is running at half speed, the back emf is half the original value, or 54 V. Find the new current from writing a loop equation for the motor circuit, from Figure 29-20.

$$\mathscr{E} - \mathscr{E}_{\text{back}} - IR = 0 \quad \rightarrow \quad I = \frac{\mathscr{E} - \mathscr{E}_{\text{back}}}{R} = \frac{120\,\text{V} - 54\,\text{V}}{5.0\,\Omega} = \boxed{13\,\text{A}}$$

44. The magnitude of the back emf is proportional to both the rotation speed and the magnetic field, from Eq. 29-4. Thus $\dfrac{\mathscr{E}}{B\omega}$ is constant.

$$\frac{\mathscr{E}_1}{B_1\omega_1} = \frac{\mathscr{E}_2}{B_2\omega_2} \quad \rightarrow \quad B_2 = \frac{\mathscr{E}_2}{\omega_2}\frac{B_1\omega_1}{\mathscr{E}_1} = \frac{(75\,\text{V})}{(2300\,\text{rpm})}\frac{B_1(1100\,\text{rpm})}{(85\,\text{V})} = 0.42B_1$$

So reduce the magnetic field to 42% of its original value.

45. (*a*) The generator voltage rating is the generator emf less the back emf. The ratio of the generator voltage rating to the generator emf is equal to the ratio of the effective resistance to the armature resistance. We solve this ratio for the generator emf, which is the same as the "no load" voltage.

$$V_{\text{nl}} = \mathscr{E} = V_{\text{load}}\frac{R_{\text{load}}}{R_{\text{nl}}} = V_{\text{load}}\frac{V_{\text{load}}/I_{\text{load}}}{R_{\text{nl}}} = 250\,\text{V}\left(\frac{250\,\text{V}/64\,\text{A}}{0.40\,\Omega}\right) = 2441\,\text{V} \approx \boxed{2.4\,\text{kV}}$$

(*b*) The generator voltage is proportional to the rotation frequency. From this proportionality we solve for the new generator voltage.

$$\frac{V_2}{V_1} = \frac{\omega_2}{\omega_1} \rightarrow V_2 = V_1\frac{\omega_2}{\omega_1} = (250\,\text{V})\frac{750\,\text{rpm}}{1000\,\text{rpm}} = \boxed{190\,\text{V}}$$

46. Because $N_{\text{S}} < N_{\text{P}}$, this is a step-down transformer. Use Eq. 29-5 to find the voltage ratio, and Eq. 29-6 to find the current ratio.

$$\frac{V_{\text{S}}}{V_{\text{P}}} = \frac{N_{\text{S}}}{N_{\text{P}}} = \frac{85\,\text{turns}}{620\,\text{turns}} = \boxed{0.14} \qquad \frac{I_{\text{S}}}{I_{\text{P}}} = \frac{N_{\text{P}}}{N_{\text{S}}} = \frac{620\,\text{turns}}{85\,\text{turns}} = \boxed{7.3}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

47. We find the ratio of the number of turns from Eq. 21-6.

$$\frac{N_S}{N_P} = \frac{V_S}{V_P} = \frac{12000\,\text{V}}{240\,\text{V}} = \boxed{50}$$

If the transformer is connected backward, the role of the turns will be reversed:

$$\frac{N_S}{N_P} = \frac{V_S}{V_P} \quad \rightarrow \quad \frac{1}{50} = \frac{V_S}{240\,\text{V}} \quad \rightarrow \quad V_S = \frac{1}{50}(240\,\text{V}) = \boxed{4.8\,\text{V}}$$

48. (*a*) Use Eqs. 29-5 and 29-6 to relate the voltage and current ratios.

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}\ ;\ \frac{I_S}{I_P} = \frac{N_P}{N_S} \quad \rightarrow \quad \frac{V_S}{V_P} = \frac{I_P}{I_S} \quad \rightarrow \quad V_S = V_P\frac{I_P}{I_S} = (120\,\text{V})\frac{0.35\,\text{A}}{7.5\,\text{A}} = \boxed{5.6\,\text{V}}$$

(*b*) Because $V_S < V_P$, this is a step-down transformer.

49. (*a*) We assume 100% efficiency, and find the input voltage from $P = IV$.

$$P = I_P V_P \quad \rightarrow \quad V_P = \frac{P}{I_P} = \frac{75\,\text{W}}{22\,\text{A}} = 3.409\,\text{V}$$

Since $V_P < V_S$, this is a step-up transformer.

(*b*) $$\frac{V_S}{V_P} = \frac{12\,\text{V}}{3.409\,\text{V}} = \boxed{3.5}$$

50. (*a*) The current in the transmission lines can be found from Eq. 25-10a, and then the emf at the end of the lines can be calculated from Kirchhoff's loop rule.

$$P_{\text{town}} = V_{\text{rms}} I_{\text{rms}} \quad \rightarrow \quad I_{\text{rms}} = \frac{P_{\text{town}}}{V_{\text{rms}}} = \frac{65\times10^6\,\text{W}}{45\times10^3\,\text{V}} = 1444\,\text{A}$$

$$\mathcal{E} - IR - V_{\text{output}} = 0 \quad \rightarrow$$

$$\mathcal{E} = IR + V_{\text{output}} = \frac{P_{\text{town}}}{V_{\text{rms}}}R + V_{\text{rms}} = \frac{65\times10^6\,\text{W}}{45\times10^3\,\text{V}}(3.0\,\Omega) + 45\times10^3\,\text{V} = 49333\,\text{V} = \boxed{49\,\text{kV}\,(\text{rms})}$$

(*b*) The power loss in the lines is given by $P_{\text{loss}} = I_{\text{rms}}^2 R$.

$$\text{Fraction wasted} = \frac{P_{\text{loss}}}{P_{\text{total}}} = \frac{P_{\text{loss}}}{P_{\text{town}} + P_{\text{loss}}} = \frac{I_{\text{rms}}^2 R}{P_{\text{town}} + I_{\text{rms}}^2 R} = \frac{(1444\,\text{A})^2(3.0\,\Omega)}{65\times10^6\,\text{W} + (1444\,\text{A})^2(3.0\,\Omega)}$$

$$= \boxed{0.088} = 8.8\%$$

51. (*a*) If the resistor *R* is connected between the terminals, then it has a voltage V_0 across it and current I_0 passing through it. Then by Ohm's law the equivalent resistance is equal to the resistance of the resistor.

$$R_{\text{eq}} = \frac{V_0}{I_0} = \boxed{R}$$

(*b*) We use Eqs. 29-5 and 29-6 to write the voltage drop and current through the resistor in terms of the source voltage and current to calculate the effective resistance.

$$R = \frac{V_s}{I_s} = \frac{\frac{N_S}{N_P}V_0}{\frac{N_P}{N_S}I_0} \rightarrow R_{\text{eq}} = \frac{V_0}{I_0} = \boxed{\left(\frac{N_P}{N_S}\right)^2 R}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

52. We set the power loss equal to 2% of the total power. Then using Eq. 25-7a we write the power loss in terms of the current (equal to the power divided by the voltage drop) and the resistance. Then, using Eq. 25-3, we calculate the cross-sectional area of each wire and the minimum wire diameter. We assume there are two lines to have a complete circuit.

$$P_{\text{loss}} = 0.020P = I^2R = \left(\frac{P}{V}\right)^2\left(\frac{\rho\ell}{A}\right) \;\rightarrow\; A = \frac{P\rho\ell}{0.020V^2} = \frac{\pi d^2}{4} \;\rightarrow$$

$$d = \sqrt{\frac{4}{0.020\pi}\frac{P\rho\ell}{V^2}} = \sqrt{\frac{4\left(225\times10^6\,\text{W}\right)\left(2.65\times10^{-8}\,\Omega\bullet\text{m}\right)2\left(185\times10^3\ \text{m}\right)}{0.020\pi\left(660\times10^3\,\text{V}\right)^2}} = 0.01796\,\text{m} \approx \boxed{1.8\,\text{cm}}$$

The transmission lines must have a diameter greater than or equal to 1.8 cm.

53. Without the transformers, we find the delivered current, which is the current in the transmission lines, from the delivered power, and the power lost in the transmission lines.

$$P_{\text{out}} = V_{\text{out}}I_{\text{line}} \;\rightarrow\; I_{\text{line}} = \frac{P_{\text{out}}}{V_{\text{out}}} = \frac{85000\,\text{W}}{120\,\text{V}} = 708.33\,\text{A}$$

$$P_{\text{lost}} = I_{\text{line}}^2R_{\text{line}} = \left(708.33\,\text{A}\right)^2 2\left(0.100\,\Omega\right) = 100346\,\text{W}$$

Thus there must be $85000\,\text{W} + 100346\,\text{W} = 185346\text{W} \approx 185\,\text{kW}$ of power generated at the start of the process.

With the transformers, to deliver the same power at 120 V, the delivered current from the step-down transformer must still be 708.33 A. Using the step-down transformer efficiency, we calculate the current in the transmission lines, and the loss in the transmission lines.

$$P_{\text{out}} = 0.99P_{\substack{\text{line}\\\text{end}}} \;\rightarrow\; V_{\text{out}}I_{\text{out}} = 0.99V_{\text{line}}I_{\text{line}} \;\rightarrow\; I_{\text{line}} = \frac{V_{\text{out}}I_{\text{out}}}{0.99V_{\text{line}}} = \frac{\left(120\,\text{V}\right)\left(708.33\,\text{A}\right)}{\left(0.99\right)\left(1200\,\text{V}\right)} = 71.548\,\text{A}$$

$$P_{\text{lost}} = I_{\text{line}}^2R_{\text{line}} = \left(71.548\,\text{A}\right)^2 2\left(0.100\,\Omega\right) = 1024\,\text{W}$$

The power to be delivered is 85000 W. The power that must be delivered to the step-down transformer is $\frac{85000\,\text{W}}{0.99} = 85859\,\text{W}$. The power that must be present at the start of the transmission must be $85859\,\text{W} + 1024\,\text{W} = 86883\,\text{W}$ to compensate for the transmission line loss. The power that must enter the transmission lines from the 99% efficient step-up transformer is $\frac{86883\,\text{W}}{0.99} = 87761 \approx 88\,\text{kW}$. So the power saved is $185346\,\text{W} - 87761\,\text{W} = 97585\,\text{W} \approx \boxed{98\,\text{kW}}$.

54. We choose a circular path centered at the origin with radius 10 cm. By symmetry the electric field is uniform along this path and is parallel to the path. We then use Eq. 29-8 to calculate the electric field at each point on this path. From the electric field we calculate the force on the charged particle.

$$\oint\vec{E}\bullet d\ell = E\left(2\pi r\right) = -\frac{d\Phi_B}{dt} = -\left(\pi r^2\right)\frac{dB}{dt}$$

$$F = QE = -Q\frac{r}{2}\frac{dB}{dt} = -\left(1.0\times10^{-6}\ \text{C}\right)\frac{0.10\ \text{m}}{2}\left(-0.10\ \text{T/s}\right) = \boxed{5.0\ \text{nN}}$$

Since the magnetic field points into the page and is decreasing, Lenz's law tells us that an induced circular current centered at the origin would flow in the clockwise direction. Therefore, the force on a positive charge along the positive x-axis would be down, or $\boxed{\text{in the } -\hat{\mathbf{j}} \text{ direction.}}$

55. (*a*) The increasing downward magnetic field creates a circular electric field along the electron path. This field applies an electric force to the electron causing it to accelerate.

(*b*) For the electrons to move in a circle, the magnetic force must provide a centripetal acceleration. With the magnetic field pointing downward, the right-hand-rule requires the electrons travel in a clockwise direction for the force to point inward.

(*c*) For the electrons to accelerate, the electric field must point in the counterclockwise direction. A current in this field would create an upward magnetic flux. So by Lenz's law, the downward magnetic field must be increasing.

(*d*) For the electrons to move in a circle and accelerate, the field must be pointing downward and increasing in magnitude. For a sinusoidal wave, the field is downward half of the time and upward the other half. For the half that it is downward its magnitude is decreasing half of the time and increasing the other half. Therefore, the magnetic field is pointing downward and increasing for only one fourth of every cycle.

56. In Example 29-14 we found the electric field along the electron's path from Faraday's law. Multiplying this field by the electron charge gives the force on the electron, and from the force, we calculate the change in tangential velocity.

$$\frac{dv}{dt} = \frac{F}{m} = E\frac{q}{m} = \frac{q}{m}\frac{r}{2}\frac{dB_{\text{avg}}}{dt}$$

We set the centripetal force on the electron equal to the magnetic force (using Eq. 27-5b) and solve for the velocity. Differentiating the velocity with respect to time (keeping the radius constant) yields a relation for the acceleration in terms of the changing magnetic field.

$$qvB = m\frac{v^2}{r} \quad \rightarrow \quad v = \frac{qBr}{m} \quad \rightarrow \quad \frac{dv}{dt} = \frac{q}{m}r\frac{dB_0}{dt}$$

Equating these two equations for the electron acceleration, we see that the change in magnetic field at the electron must equal $\frac{1}{2}$ of the average change in magnetic field. This relation is satisfied if at all times $B_0 = \frac{1}{2}B_{\text{avg}}$.

57. (*a*) The electric field is the change in potential across the rod (obtained from Ohm's law) divided by the length of the rod.

$$E = \frac{\Delta V}{\ell} = \boxed{\frac{IR}{\ell}}$$

(*b*) Again the electric field is the change in potential across the rod divided by the length of the rod. The electric potential is the supplied potential less the motional emf found using Eq. 29-3 and the results of Problem 34(b).

$$E = \frac{\Delta V}{\ell} = \frac{\mathscr{E}_0 - B\ell v}{\ell} = \frac{\mathscr{E}_0 - B\ell\,\mathscr{E}_0/B\ell\left(1 - e^{-\frac{B^2\ell^2}{mR}t}\right)}{\ell} = \boxed{\frac{\mathscr{E}_0}{\ell}e^{-\frac{B^2\ell^2}{mR}t}}$$

58. (*a*) The clockwise current in the left-hand loop produces a magnetic field which is into the page within the loop and out of the page outside the loop. Thus the right-hand loop is in a magnetic field that is directed out of the page. Before the current in the left-hand loop reaches its steady state, there will be an induced current in the right-hand loop that will produce a magnetic field into the page to oppose the increase of the field from the left-hand loop. Thus the induced current will be clockwise.

(*b*) After a long time, the current in the left-hand loop is constant, so there will be no induced current in the right-hand coil.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) If the second loop is pulled to the right, the magnetic field out of the page from the left-hand loop through the second loop will decrease. During the motion, there will be an induced current in the right-hand loop that will produce a magnetic field out of the page to oppose the decrease of the field from the left-hand loop. Thus the induced current will be counterclockwise.

59. The electrical energy is dissipated because there is current flowing in a resistor. The power dissipation by a resistor is given by $P = I^2R$, and so the energy dissipated is $E = P\Delta t = I^2R\Delta t$. The current is created by the induced emf caused by the changing B-field. The average induced emf is given by the "difference" version of Eq. 29-2b.

$$\mathscr{E} = -\frac{\Delta\Phi_B}{\Delta t} = -\frac{A\Delta B}{\Delta t} \qquad I = \frac{\mathscr{E}}{R} = -\frac{A\Delta B}{R\Delta t}$$

$$E = P\Delta t = I^2R\Delta t = \frac{A^2(\Delta B)^2}{R^2(\Delta t)^2}R\Delta t = \frac{A^2(\Delta B)^2}{R(\Delta t)} = \frac{\left[(0.270\,\text{m})^2\right]^2\left[(0-0.755\,\text{T})\right]^2}{(7.50\,\Omega)(0.0400\,\text{s})}$$

$$= \boxed{1.01\times10^{-2}\,\text{J}}$$

60. Because there are perfect transformers, the power loss is due to resistive heating in the transmission lines. Since the town requires 65 MW, the power at the generating plant must be $\frac{65\,\text{MW}}{0.985} = 65.99$ MW. Thus the power lost in the transmission is 0.99 MW. This can be used to determine the current in the transmission lines.

$$P = I^2R \;\rightarrow\; I = \sqrt{\frac{P}{R}} = \sqrt{\frac{0.99\times10^6\,\text{W}}{2(85\,\text{km})0.10\,\Omega/\text{km}}} = 241.3\,\text{A}$$

To produce 65.99 MW of power at 241.3 A requires the following voltage.

$$V = \frac{P}{I} = \frac{65.99\times10^6\,\text{W}}{241.3\,\text{A}} = 2.73\times10^5\,\text{V} \approx \boxed{270\,\text{kV}}$$

61. The charge on the capacitor can be written in terms of the voltage across the battery and the capacitance using Eq. 24-1. When fully charged the voltage across the capacitor will equal the emf of the loop, which we calculate using Eq. 29-2b.

$$Q = CV = C\frac{d\Phi_B}{dt} = CA\frac{dB}{dt} = \left(5.0\times10^{-12}\ \text{F}\right)\left(12\ \text{m}^2\right)\left(10\ \text{T/s}\right) = \boxed{0.60\ \text{nC}}$$

62. (*a*) From the efficiency of the transformer, we have $P_S = 0.85P_P$. Use this to calculate the current in the primary.

$$P_S = 0.85P_P = 0.85I_PV_P \;\rightarrow\; I_P = \frac{P_S}{0.85V_P} = \frac{75\,\text{W}}{0.85(110\,\text{V})} = 0.8021\,\text{A} \approx \boxed{0.80\,\text{A}}$$

(*b*) The voltage in both the primary and secondary is proportional to the number of turns in the respective coil. The secondary voltage is calculated from the secondary power and resistance since $P = V^2/R$.

$$\frac{N_P}{N_S} = \frac{V_P}{V_S} = \frac{V_P}{\sqrt{P_SR_S}} = \frac{110\,\text{V}}{\sqrt{(75\,\text{W})(2.4\,\Omega)}} = \boxed{8.2}$$

63. (*a*) The voltage drop across the lines is due to the resistance.

$$V_{\text{out}} = V_{\text{in}} - IR = 42000\,\text{V} - (740\,\text{A})(2)(0.80\,\Omega) = 40816\,\text{V} \approx \boxed{41\,\text{kV}}$$

(*b*) The power input is given by $P_{\text{in}} = IV_{\text{in}}$.

$$P_{\text{in}} = IV_{\text{in}} = (740\,\text{A})(42000\,\text{V}) = 3.108\times10^{7}\,\text{W} \approx \boxed{3.1\times10^{7}\,\text{W}}$$

(*c*) The power loss in the lines is due to the current in the resistive wires.

$$P_{\text{loss}} = I^2R = (740\,\text{A})^2\,(1.60\,\Omega) = 8.76\times10^{5}\,\text{W} \approx \boxed{8.8\times10^{5}\,\text{W}}$$

(*d*) The power output is given by $P_{\text{out}} = IV_{\text{out}}$.

$$P_{\text{out}} = IV_{\text{out}} = (740\,\text{A})(40816\,\text{V}) = 3.020\times10^{7}\,\text{W} \approx \boxed{3.0\times10^{7}\,\text{W}}.$$

This could also be found by subtracting the power lost from the input power.

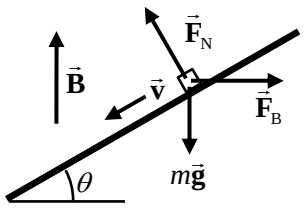
$$P_{\text{out}} = P_{\text{in}} - P_{\text{loss}} = 3.108\times10^{7}\,\text{W} - 8.76\times10^{5}\,\text{W} = 3.020\times10^{7}\,\text{W} \approx \boxed{3.0\times10^{7}\,\text{W}}$$

64. We find the current in the transmission lines from the power transmitted to the user, and then find the power loss in the lines.

$$P_{\text{T}} = I_{\text{L}}V \;\rightarrow\; I_{\text{L}} = \frac{P_{\text{T}}}{V} \qquad P_{\text{L}} = I_{\text{L}}^2R_{\text{L}} = \left(\frac{P_{\text{T}}}{V}\right)^2 R_{\text{L}} = \boxed{\frac{P_{\text{T}}^2R_{\text{L}}}{V^2}}$$

65. (*a*) Because $V_{\text{S}} < V_{\text{P}}$, this is a $\boxed{\text{step-down}}$ transformer.

(*b*) Assuming 100% efficiency, the power in both the primary and secondary is 35 W. Find the current in the secondary from the relationship $P = IV$.



$$P_{\text{S}} = I_{\text{S}}V_{\text{S}} \;\rightarrow\; I_{\text{S}} = \frac{P_{\text{S}}}{V_{\text{S}}} = \frac{35\,\text{W}}{12\,\text{V}} = \boxed{2.9\,\text{A}}$$

(*c*) $P_{\text{P}} = I_{\text{P}}V_{\text{P}} \;\rightarrow\; I_{\text{P}} = \dfrac{P_{\text{P}}}{V_{\text{P}}} = \dfrac{35\,\text{W}}{120\,\text{V}} = \boxed{0.29\,\text{A}}$

(*d*) Find the resistance of the bulb from Ohm's law. The bulb is in the secondary circuit.

$$V_{\text{S}} = I_{\text{S}}R \;\rightarrow\; R = \frac{V_{\text{S}}}{I_{\text{S}}} = \frac{12\,\text{V}}{2.9\,\text{A}} = \boxed{4.1\,\Omega}$$

66. A side view of the rail and bar is shown in the figure. From Section 21-3, the emf in the bar is produced by the components of the magnetic field, the length of the bar, and the velocity of the bar, which are all mutually perpendicular. The magnetic field and the length of the bar are already perpendicular. The component of the velocity of the bar that is perpendicular to the magnetic field is $v\cos\theta$, and so the induced emf is given by the following.

$$\mathscr{E} = B\ell v\cos\theta$$

This produces a current in the wire, which can be found by Ohm's law. That current is pointing into the page on the diagram.

$$I = \frac{\mathscr{E}}{R} = \frac{B\ell v\cos\theta}{R}$$

Because the current is perpendicular to the magnetic field, the force on the wire from the magnetic field can be calculated from Eq. 27-2, and will be horizontal, as shown in the diagram.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$F_B = I\ell B = \frac{B\ell v\cos\theta}{R}\ell B = \frac{B^2\ell^2 v\cos\theta}{R}$$

For the wire to slide down at a steady speed, the net force along the rail must be zero. Write Newton's second law for forces along the rail, with up the rail being positive.

$$F_{\text{net}} = F_B\cos\theta - mg\sin\theta = 0 \quad\rightarrow\quad \frac{B^2\ell^2 v\cos^2\theta}{R} = mg\sin\theta \quad\rightarrow$$

$$v = \frac{Rmg\sin\theta}{B^2\ell^2\cos^2\theta} = \frac{(0.60\,\Omega)(0.040\,\text{kg})(9.80\,\text{m/s}^2)\sin 6.0^\circ}{(0.55\,\text{T})^2(0.32\,\text{m})^2\cos^2 6.0^\circ} = \boxed{0.80\,\text{m/s}}$$

67. The induced current in the coil is the induced emf divided by the resistance. The induced emf is found from the changing flux by Eq. 29-2a. The magnetic field of the solenoid, which causes the flux, is given by Eq. 28-4. For the area used in Eq. 29-2a, the cross-sectional area of the solenoid (not the coil) must be used, because all of the magnetic flux is inside the solenoid.

$$I = \frac{\mathscr{E}_{\text{ind}}}{R} \qquad \left|\mathscr{E}_{\text{ind}}\right| = N_{\text{coil}}\frac{d\Phi}{dt} = N_{\text{coil}}A_{\text{sol}}\frac{dB_{\text{sol}}}{dt} \qquad B_{\text{sol}} = \mu_0\frac{N_{\text{sol}}I_{\text{sol}}}{\ell_{\text{sol}}}$$

$$I = \frac{N_{\text{coil}}A_{\text{sol}}\mu_0\dfrac{N_{\text{sol}}}{\ell_{\text{sol}}}\dfrac{dI_{\text{sol}}}{dt}}{R} = \frac{N_{\text{coil}}A_{\text{sol}}\mu_0}{R}\frac{N_{\text{sol}}}{\ell_{\text{sol}}}\frac{dI_{\text{sol}}}{dt}$$

$$= \frac{(150\,\text{turns})\pi(0.045\,\text{m})^2(4\pi\times10^{-7}\,\text{T}\cdot\text{m/A})}{12\,\Omega}\frac{(230\text{ turns})}{(0.01\,\text{m})}\frac{2.0\,\text{A}}{0.10\,\text{s}} = \boxed{4.6\times10^{-2}\,\text{A}}$$

As the current in the solenoid increases, a magnetic field from right to left is created in the solenoid and the loop. The induced current will flow in such a direction as to oppose that field, and so must flow from left to right through the resistor.

68. The average induced emf is given by the "difference" version of Eq. 29-2b. Because the coil orientation changes by 180°, the change in flux is the opposite of twice the initial flux. The average current is the induced emf divided by the resistance, and the charge that flows in a given time is the current times the elapsed time.

$$\mathscr{E}_{\text{avg}} = -N\frac{\Delta\Phi_B}{\Delta t} = -NA\frac{\Delta B}{\Delta t} = -NA\frac{\left[(-B)-(+B)\right]}{\Delta t} = \frac{2NAB}{\Delta t}$$

$$Q = I\Delta t = \frac{\mathscr{E}_{\text{avg}}}{R}\Delta t = \frac{\left(\dfrac{2NAB}{\Delta t}\right)}{R}\Delta t = \frac{2NAB}{R} \quad\rightarrow\quad \boxed{B = \frac{RQ}{2NA}}$$

69. Calculate the current in the ring from the magnitude of the emf (from Eq. 29-2a) divided by the resistance. Setting the current equal to the derivative of the charge, we integrate the charge and flux over the 90° rotation, with the flux given by Eq. 29-1a. This results in the total charge flowing past a given point in the ring. Note that the initial orientation of the ring area relative to the magnetic field is not given.

$$\mathscr{E} = \frac{d\Phi_B}{dt} \;;\; I = \frac{\mathscr{E}}{R} = \frac{dQ}{dt} \;\rightarrow\; dQ = \frac{\mathscr{E}}{R}dt \;\rightarrow$$

$$Q = \int dQ = \int \frac{\mathscr{E}}{R}dt = \frac{1}{R}\int \frac{d\Phi}{dt}dt = \frac{1}{R}\int d\Phi = \frac{1}{R}\int_{BA\cos(\theta)}^{BA\cos(\theta+90°)} d\Phi = \frac{BA\left[\cos(\theta+90°)-\cos\theta\right]}{R}$$

$$= \frac{(0.23\text{T})\pi(0.030\text{m})^2}{0.025\Omega}\left[\cos(\theta+90°)-\cos\theta\right] = 0.02601\text{C}\left[\cos(\theta+90°)-\cos\theta\right]$$

To find the maximum charge, we set the derivative of the charge with respect to the starting angle, θ, equal to zero to find the extremes. Inserting the maximum angle into our equation, we find the maximum charge passing through the ring. Finally, we divide the maximum charge by the charge of a single electron to obtain the number of electrons passing the point in the ring.

$$\frac{dQ}{d\theta} = 0.02601\text{ C}\left[-\sin(\theta+90°)+\sin\theta\right] = 0.02601\text{ C}\left[-\cos\theta+\sin\theta\right] = 0 \;\rightarrow\; \tan\theta = 1 \;\rightarrow$$

$$\theta = 45° \text{ or } 225°$$

$$Q_{\max} = 0.02601\text{ C}\left[\cos(225°+90°)-\cos 225°\right] = 0.03678\text{ C}$$

$$N_{\max} = \frac{Q_{\max}}{q} = \frac{0.03678\text{ C}}{1.60\times10^{-19}\text{ C/e}} = \boxed{2.3\times10^{17}\text{ electrons}}$$

70. The coil should have a diameter about equal to the diameter of a standard flashlight D-cell so that it will be simple to hold and use. This would give the coil a radius of about 1.5 cm. As the magnet passes through the coil the field changes direction, so the change in flux for each pass is twice the maximum flux. Let us assume that the magnet is shaken with a frequency of about two shakes per second, so the magnet passes through the coil four times per second. We obtain the number of turns in the coil using Eq. 29-2b.

$$N = \frac{\mathscr{E}}{\Delta\Phi/\Delta t} = \frac{\mathscr{E}\Delta t}{\Delta\Phi} = \frac{\mathscr{E}\Delta t}{2B_0A} = \frac{(3.0\text{V})(0.25\text{s})}{2(0.050\text{T})\pi(0.015\text{m})^2} \approx \boxed{11{,}000\text{ turns}}$$

71. (*a*) Since the coils are directly connected to the wheels, the torque provided by the motor (Eq. 27-9) balances the torque caused by the frictional force.

$$NIAB = Fr \rightarrow I = \frac{Fr}{NAB} = \frac{(250\text{ N})(0.29\text{ m})}{270(0.12\text{ m})(0.15\text{ m})(0.60\text{ T})} = 24.86\text{ A} \approx \boxed{25\text{ A}}$$

(*b*) To maintain this speed the power loss due to the friction (Eq. 8-21) must equal the net power provided by the coils. The power provided by the coils is the current through the coils multiplied by the back emf.

$$P = Fv = I\mathscr{E}_{\text{back}} \rightarrow \mathscr{E}_{\text{back}} = \frac{Fv}{I} = \frac{(250\text{ N})(35\text{km/h})}{24.86\text{ A}}\left(\frac{1000\text{ m/km}}{3600\text{ s/h}}\right) = 97.76\text{ V} \approx \boxed{98\text{ V}}$$

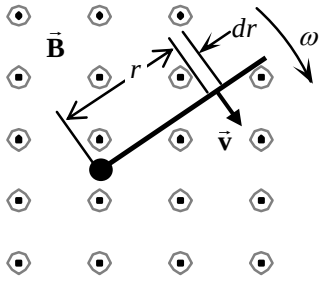
(*c*) The power dissipated in the coils is the difference between the power produced by the coils and the net power provided to the wheels.

$$P_{\text{loss}} = P - P_{\text{net}} = I\mathscr{E} - I\mathscr{E}_{\text{back}} = (24.86\text{ A})(120\text{ V} - 97.76\text{ V}) = 553\text{ W} \approx \boxed{600\text{ W}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*d*) We divide the net power by the total power to determine the percent used to drive the car.

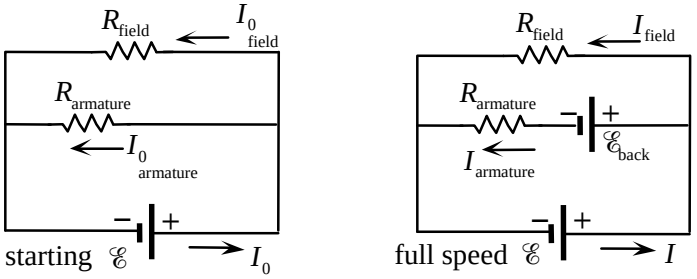
$$\frac{P_{\text{net}}}{P} = \frac{I\mathscr{E}_{\text{back}}}{I\mathscr{E}} = \frac{97.76\,\text{V}}{120\,\text{V}} = 0.8147 \approx \boxed{81\%}$$



72. The energy is dissipated by the resistance. The power dissipated by the resistor is given by Eq. 25-7b, and the energy is the integral of the power over time. The induced emf is given by Eq. 29-2a.

$$\mathscr{E} = -N\frac{d\Phi_B}{dt} = -NA\frac{dB}{dt} = \frac{NAB_0}{\tau}e^{-t/\tau} \;\; ; \;\; P = I^2R = \frac{\mathscr{E}^2}{R} = \left(\frac{N^2A^2B_0^2}{R\tau^2}\right)e^{-2t/\tau}$$

$$E = \int P\,dt = \int_0^t \left(\frac{N^2A^2B_0^2}{R\tau^2}\right)e^{-2t/\tau}dt = \left(\frac{N^2A^2B_0^2}{R\tau^2}\right)\left(-\frac{\tau}{2}e^{-2t/\tau}\right)_0^t = \frac{(NAB_0)^2}{2R\tau}\left(1-e^{-2t/\tau}\right)$$



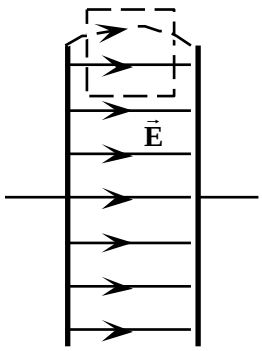
$$= \frac{\left[18\pi\left(0.100\,\text{m}\right)^2\left(0.50\,\text{T}\right)\right]^2}{2\left(2.0\,\Omega\right)\left(0.10\,\text{s}\right)}\left(1-e^{-2t/(0.10\,\text{s})}\right) = \boxed{\left(0.20\,\text{J}\right)\left(1-e^{-20t}\right)}$$

73. The total emf across the rod is the integral of the differential emf across each small segment of the rod. For each differential segment, *dr*, the differential emf is given by the differential version of Eq. 29-3. The velocity is the angular speed multiplied by the radius. The figure is a top view of the spinning rod.

$$d\mathscr{E} = Bvd\ell = B\omega r\,dr \;\; \rightarrow \;\; \mathscr{E} = \int d\mathscr{E} = \int_0^\ell B\omega r\,dr = \boxed{\tfrac{1}{2}B\omega\ell^2}$$

74. (*a*)

(*b*) At startup there is no back emf. We therefore treat the circuit as two parallel resistors, each with the same voltage drop. The current through the battery is the sum of the currents through each resistor.



$$I = I_{0\,\text{field}} + I_{0\,\text{armature}} = \frac{\mathscr{E}}{R_{\text{field}}} + \frac{\mathscr{E}}{R_{\text{armature}}} = \frac{115\,\text{V}}{36.0\,\Omega} + \frac{115\,\text{V}}{3.00\,\Omega} = \boxed{41.5\,\text{A}}$$

(*c*) At full speed the back emf decreases the voltage drop across the armature resistor.

$$I = I_{\text{field}} + I_{\text{armature}} = \frac{\mathscr{E}}{R_{\text{field}}} + \frac{\mathscr{E}-\mathscr{E}_{\text{back}}}{R_{\text{armature}}} = \frac{115\,\text{V}}{36.0\,\Omega} + \frac{115\,\text{V}-105\,\text{V}}{3.00\,\Omega} = \boxed{6.53\,\text{A}}$$

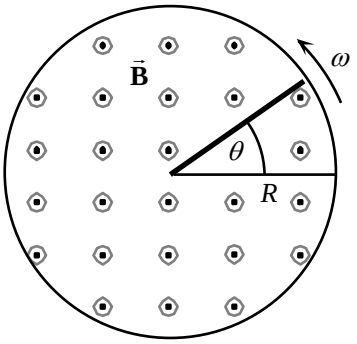
75. Assume that the electric field does not fringe, but only has a horizontal component between the plates and zero field outside the plates. Apply Faraday's law (Eq. 29-8) to this situation for a rectangular loop with one horizontal leg inside the plates and the second horizontal leg outside the plates. We integrate around this path in the counterclockwise direction. Since the field only has a horizontal component between the plates, only the horizontal leg will contribute to the electric field integral. Since the field is constant in this region, the integral is the electric field times the length of the leg.



$$\oint \vec{\mathbf{E}} \cdot d\vec{\ell} = \int_0^{\ell} E d\ell = E\ell$$

For a static electric field, the magnetic flux is unchanging. Therefore $\frac{d\Phi_B}{dt} = 0$.

Using Faraday's law, we have $\oint \vec{\mathbf{E}} \cdot d\vec{\ell} = -\frac{d\Phi_B}{dt} \rightarrow E\ell = 0$, which is not possible. Thus one of the initial assumptions must be false. We conclude that the field must have some fringing at the edges.

76. The total emf across the disk is the integral of the differential emf across each small segment of the radial line passing from the center of the disk to the edge. For each differential segment, *dr*, the emf is given by the differential version of Eq. 29-3. The velocity is the angular speed multiplied by the radius. Since the disk is rotating in the counterclockwise direction, and the field is out of the page, the emf is increasing with increasing radius. Therefore the rim is at the higher potential.

$$d\mathscr{E} = Bvd\ell = B\omega r dr \rightarrow$$

$$\mathscr{E} = \int d\mathscr{E} = \int_0^R B\omega r dr = \boxed{\tfrac{1}{2} B\omega R^2}$$

77. We set the electric field equal to the negative gradient of the electric potential (Eq. 23-8), with the differential potential given by Eq. 29-3, as in Problem 76.

$$\vec{\mathbf{E}} = -\frac{d\mathscr{E}}{dr}\hat{\mathbf{r}} = -\frac{Br\omega dr}{dr}\hat{\mathbf{r}} = \boxed{-Br\omega\hat{\mathbf{r}}}$$

The electric field has magnitude $Br\omega$ and points radially inwards, toward the center of the disk.

78. The emf around the loop is equal to the time derivative of the flux, as in Eq. 29-2a. Since the area of the coil is constant, the time derivative of the flux is equal to the derivative of the magnetic field multiplied by the area of the loop. To calculate the emf in the loop we add the voltage drop across the capacitor to the voltage drop across the resistor. The current in the loop is the derivative of the charge on the capacitor (Eq. 24-1).

$$I = \frac{dQ}{dt} = \frac{dCV}{dt} = \frac{d}{dt}\left[CV_0\left(1 - e^{-t/\tau}\right)\right] = \frac{CV_0}{\tau}e^{-t/\tau} = \frac{V_0}{R}e^{-t/\tau}$$

$$\mathscr{E} = IR + V_C = \left(\frac{V_0}{R}e^{-t/\tau}\right)R + V_0\left(1 - e^{-t/\tau}\right) = V_0 = \frac{d\Phi_B}{dt} = A\frac{dB}{dt} = \pi r^2\frac{dB}{dt} \rightarrow \boxed{\frac{dB}{dt} = \frac{V_0}{\pi r^2}}$$

Since the charge is building up on the top plate of the capacitor, the induced current is flowing clockwise. By Lenz's law this produces a downward flux, so the external downward magnetic field must be decreasing.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

79. (*a*) As the loop falls out of the magnetic field, the flux through the loop decreases with time creating an induced emf in the loop. The current in the loop is equal to the emf divided by the resistance, which can be written in terms of the resistivity using Eq. 25-3.

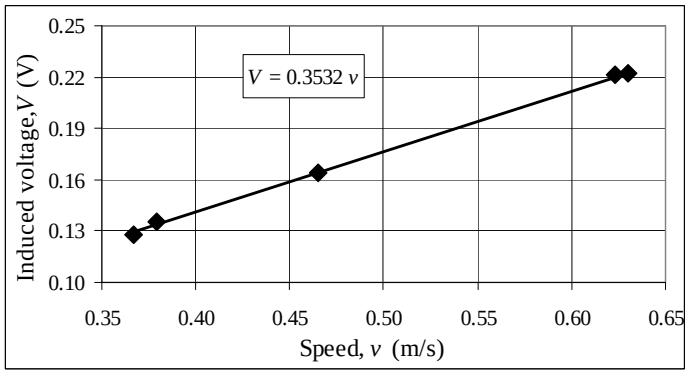
$$I = \frac{\mathscr{E}}{R} = \left(\frac{\pi d^2/4}{\rho 4\ell}\right)\frac{d\Phi_B}{dt} = \left(\frac{\pi d^2}{16\rho\ell}\right)B\frac{dA}{dt} = \frac{\pi d^2}{16\rho\ell}B\ell v$$

This current induces a force on the three sides of the loop in the magnetic field. The forces on the two vertical sides are equal and opposite and therefore cancel.

$$F = I\ell B = \frac{\pi d^2}{16\rho\ell}B\ell v\ell B = \boxed{\frac{\pi d^2 B^2 \ell v}{16\rho}}$$

By Lenz's law this force is upward to slow the decrease in flux.

(*b*) Terminal speed will occur when the gravitational force is equal to the magnetic force.



$$F_g = \rho_m\left(4\pi\ell\frac{d^2}{4}\right)g = \frac{\pi d^2 B^2 \ell v_T}{16\rho} \rightarrow v_T = \boxed{\frac{16\rho\rho_m g}{B^2}}$$

(*c*) We calculate the terminal velocity using the given magnetic field, the density of copper from Table 13-1, and the resistivity of copper from Table 25-1

$$v_T = \frac{16\left(8.9\times10^3\ \text{kg/m}^3\right)\left(1.68\times10^{-8}\ \Omega\text{m}\right)\left(9.80\ \text{m/s}^2\right)}{\left(0.80\ \text{T}\right)^2} = \boxed{3.7\ \text{cm/s}}$$

80. (*a*) See the graph, with best fit linear trend line (with the *y* intercept forced to be 0).

(*b*) The theoretical slope is the induced voltage divided by the velocity. Take the difference between the experimental value found in part (*a*) and the theoretical value and divide the result by the theoretical value to obtain the percent difference.

$$\%\ \text{diff} = \left(\frac{m_{\text{exp}} - m_{\text{theory}}}{m_{\text{theory}}}\right)100 = \left(\frac{m_{\text{exp}}}{BN\ell} - 1\right)100 = \left(\frac{0.3532\ \text{V•s/m}}{(0.126\text{T})(50)(0.0561\text{m})} - 1\right)100$$

$$= \boxed{-0.065\%}$$

(*c*) Use the theoretical equation to calculate the voltage at each experimental speed. Then calculate the percent difference at each speed.

Speed (m/s)	Induced Voltage (V)	Theoretical Induced Voltage (V)	% diff.
0.367	0.128	0.130	– 1.32%
0.379	0.135	0.134	0.78%
0.465	0.164	0.164	– 0.21%
0.623	0.221	0.220	0.37%
0.630	0.222	0.223	– 0.30%

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH29.XLS," on tab "Problem 29.80."

CHAPTER 30: Inductance, Electromagnetic Oscillations, and AC Circuits

Responses to Questions

1. (*a*) For the maximum value of the mutual inductance, place the coils close together, face to face, on the same axis.
   (*b*) For the least possible mutual inductance, place the coils with their faces perpendicular to each other.

2. The magnetic field near the end of the first solenoid is less than it is in the center. Therefore the flux through the second coil would be less than that given by the formula, and the mutual inductance would be lower.

3. Yes. If two coils have mutual inductance, then they each have the capacity for self-inductance. Any coil that experiences a changing current will have a self-inductance.

4. The energy density is greater near the center of a solenoid, where the magnetic field is greater.

5. To create the greatest self-inductance, bend the wire into as many loops as possible. To create the least self-inductance, leave the wire as a straight piece of wire.

6. (*a*) No. The time needed for the *LR* circuit to reach a given fraction of its maximum possible current depends on the time constant, $\tau = L/R$, which is independent of the emf.
   (*b*) Yes. The emf determines the maximum value of the current ($I_{max} = V_0/R$,) and therefore will affect the time it takes to reach a particular value of current.

7. A circuit with a large inductive time constant is resistant to changes in the current. When a switch is opened, the inductor continues to force the current to flow. A large charge can build up on the switch, and may be able to ionize a path for itself across a small air gap, creating a spark.

8. Although the current is zero at the instant the battery is connected, the rate at which the current is changing is a maximum and therefore the rate of change of flux through the inductor is a maximum. Since, by Faraday's law, the induced emf depends on the rate of change of flux and not the flux itself, the emf in the inductor is a maximum at this instant.

9. When the capacitor has discharged completely, energy is stored in the magnetic field of the inductor. The inductor will resist a change in the current, so current will continue to flow and will charge the capacitor again, with the opposite polarity.

10. Yes. The instantaneous voltages across the different elements in the circuit will be different, but the current through each element in the series circuit is the same.

11. The energy comes from the generator. (A generator is a device that converts mechanical energy to electrical energy, so ultimately, the energy came from some mechanical source, such as falling water.) Some of the energy is dissipated in the resistor and some is stored in the fields of the capacitor and the inductor. An increase in *R* results in an increase in energy dissipated by the circuit. *L*, *C*, *R*, and the frequency determine the current flow in the circuit, which determines the power supplied by generator.

12. $X_L = X_C$ at the resonant frequency. If the circuit is predominantly inductive, such that $X_L > X_C$, then the frequency is greater than the resonant frequency and the voltage leads the current. If the circuit is predominantly capacitive, such that $X_C > X_L$, then the frequency is lower than the resonant frequency and the current leads the voltage. Values of L and C cannot be meaningfully compared, since they are in different units. Describing the circuit as "inductive" or "capacitive" relates to the values of X_L and X_C, which are both in ohms and which both depend on frequency.

13. Yes. When ω approaches zero, X_L approaches zero, and X_C becomes infinitely large. This is consistent with what happens in an ac circuit connected to a dc power supply. For the dc case, ω is zero and X_L will be zero because there is no changing current to cause an induced emf. X_C will be infinitely large, because steady direct current cannot flow across a capacitor once it is charged.

14. The impedance in an *LRC* circuit will be a minimum at resonance, when $X_L = X_C$. At resonance, the impedance equals the resistance, so the smallest R possible will give the smallest impedance.

15. Yes. The power output of the generator is $P = IV$. When either the instantaneous current or the instantaneous voltage in the circuit is negative, and the other variable is positive, the instantaneous power output can be negative. At this time either the inductor or the capacitor is discharging power back to the generator.

16. Yes, the power factor depends on frequency because X_L and X_C, and therefore the phase angle, depend on frequency. For example, at resonant frequency, $X_L = X_C$, the phase angle is 0°, and the power factor is one. The average power dissipated in an *LRC* circuit also depends on frequency, since it depends on the power factor: $P_{\text{avg}} = I_{\text{rms}} V_{\text{rms}} \cos\varphi$. Maximum power is dissipated at the resonant frequency. The value of the power factor decreases as the frequency gets farther from the resonant frequency.

17. (*a*) The impedance of a pure resistance is unaffected by the frequency of the source emf.
(*b*) The impedance of a pure capacitance decreases with increasing frequency.
(*c*) The impedance of a pure inductance increases with increasing frequency.
(*d*) In an *LRC* circuit near resonance, small changes in the frequency will cause large changes in the impedance.
(*e*) For frequencies far above the resonance frequency, the impedance of the *LRC* circuit is dominated by the inductive reactance and will increase with increasing frequency. For frequencies far below the resonance frequency, the impedance of the *LRC* circuit is dominated by the capacitive reactance and will decrease with increasing frequency.

18. In all three cases, the energy dissipated decreases as R approaches zero. Energy oscillates between being stored in the field of the capacitor and being stored in the field of the inductor.
(*a*) The energy stored in the fields (and oscillating between them) is a maximum at resonant frequency and approaches an infinite value as R approaches zero.
(*b*) When the frequency is near resonance, a large amount of energy is stored in the fields but the value is less than the maximum value.
(*c*) Far from resonance, a much lower amount of energy is stored in the fields.

19. In an *LRC* circuit, the current and the voltage in the circuit both oscillate. The energy stored in the circuit also oscillates and is alternately stored in the magnetic field of the inductor and the electric field of the capacitor.

20. In an *LRC* circuit, energy oscillates between being stored in the magnetic field of the inductor and being stored in the electric field of the capacitor. This is analogous to a mass on a spring, with energy alternating between kinetic energy of the mass and spring potential energy as the spring compresses and extends. The energy stored in the magnetic field is analogous to the kinetic energy of the moving mass, and *L* corresponds to the mass, *m*, on the spring. The energy stored in the electric field of the capacitor is analogous to the spring potential energy, and *C* corresponds to the reciprocal of the spring constant, 1/*k*.

Solutions to Problems

1. (*a*) The mutual inductance is found in Example 30-1.

$$M = \frac{\mu N_1 N_2 A}{\ell} = \frac{1850\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(225)(115)\pi\left(0.0200\,\text{m}\right)^2}{2.44\,\text{m}} = \boxed{3.10\times10^{-2}\,\text{H}}$$

(b) The emf induced in the second coil can be found from Eq. 30-3b.

$$\mathscr{E}_2 = -M\frac{dI_1}{dt} = -M\frac{\Delta I_1}{\Delta t} = \left(-3.10\times10^{-2}\,\text{H}\right)\frac{(-12.0\,\text{A})}{0.0980\,\text{ms}} = \boxed{3.79\,\text{V}}$$

2. If we assume the outer solenoid is carrying current I_1, then the magnetic field inside the outer solenoid is $B = \mu_0 n_1 I_1$. The flux in each turn of the inner solenoid is $\Phi_{21} = B\pi r_2^2 = \mu_0 n_1 I_1 \pi r_2^2$. The mutual inductance is given by Eq. 30-1.

$$M = \frac{N_2\Phi_{21}}{I_1} = \frac{n_2\ell\mu_0 n_1 I_1 \pi r_2^2}{I_1} \quad\rightarrow\quad \frac{M}{\ell} = \boxed{\mu_0 n_1 n_2 \pi r_2^2}$$

3. We find the mutual inductance of the inner loop. If we assume the outer solenoid is carrying current I_1, then the magnetic field inside the outer solenoid is $B = \mu_0\frac{N_1}{\ell}I_1$. The magnetic flux through each loop of the small coil is the magnetic field times the area perpendicular to the field. The mutual inductance is given by Eq. 30-1.

$$\Phi_{21} = BA_2\sin\theta = \mu_0\frac{N_1 I_1}{\ell}A_2\sin\theta \ ;\ M = \frac{N_2\Phi_{21}}{I_1} = \frac{N_2\mu_0\dfrac{N_1 I_1}{\ell}A_2\sin\theta}{I_1} = \boxed{\frac{\mu_0 N_1 N_2 A_2\sin\theta}{\ell}}$$

4. We find the mutual inductance of the system using Eq. 30-1, with the flux equal to the integral of the magnetic field of the wire (Eq. 28-1) over the area of the loop.

$$M = \frac{\Phi_{12}}{I_1} = \frac{1}{I_1}\int_{\ell_1}^{\ell_2}\frac{\mu_0 I_1}{2\pi r}w\,dr = \boxed{\frac{\mu_0 w}{2\pi}\ln\left(\frac{\ell_2}{\ell_1}\right)}$$

5. Find the induced emf from Eq. 30-5.

$$\mathscr{E} = -L\frac{dI}{dt} = -L\frac{\Delta I}{\Delta t} = -\left(0.28\,\text{H}\right)\frac{(10.0\,\text{A} - 25.0\,\text{A})}{0.36\,\text{s}} = \boxed{12\,\text{V}}$$

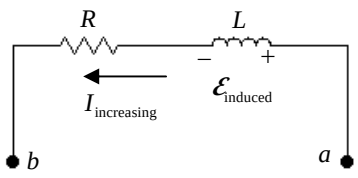
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

6. Use the relationship for the inductance of a solenoid, as given in Example 30-3.

$$L = \frac{\mu_0 N^2 A}{\ell} \quad \rightarrow \quad N = \sqrt{\frac{L\ell}{\mu_0 A}} = \sqrt{\frac{(0.13\,\text{H})(0.300\,\text{m})}{(4\pi\times10^{-7}\,\text{T}\cdot\text{m/A})\pi(0.021\,\text{m})^2}} \approx \boxed{4700\,\text{turns}}$$

7. Because the current in increasing, the emf is negative. We find the self-inductance from Eq. 30-5.

$$\mathscr{E} = -L\frac{dI}{dt} = -L\frac{\Delta I}{\Delta t} \quad \rightarrow \quad L = -\mathscr{E}\frac{\Delta t}{\Delta I} = -(-2.50\,\text{V})\frac{0.0120\,\text{s}}{[0.0250\,\text{A}-(-0.0280\,\text{A})]} = \boxed{0.566\,\text{H}}$$



8. (*a*) The number of turns can be found from the inductance of a solenoid, which is derived in Example 30-3.

$$L = \frac{\mu_0 N^2 A}{\ell} = \frac{(4\pi\times10^{-7}\,\text{T}\cdot\text{m/A})(2800)^2\,\pi(0.0125\,\text{m})^2}{(0.217\,\text{m})} = 0.02229\,\text{H} \approx \boxed{0.022\,\text{H}}$$

(*b*) Apply the same equation again, solving for the number of turns.

$$L = \frac{\mu_0 N^2 A}{\ell} \quad \rightarrow \quad N = \sqrt{\frac{L\ell}{\mu_0 A}} = \sqrt{\frac{(0.02229\,\text{H})(0.217\,\text{m})}{(1200)(4\pi\times10^{-7}\,\text{T}\cdot\text{m/A})\pi(0.0125\,\text{m})^2}} \approx \boxed{81\,\text{turns}}$$

9. We draw the coil as two elements in series, and pure resistance and a pure inductance. There is a voltage drop due to the resistance of the coil, given by Ohm's law, and an induced emf due to the inductance of the coil, given by Eq. 30-5. Since the current is increasing, the inductance will create a potential difference to oppose the increasing current, and so there is a drop in the potential due to the inductance. The potential difference across the coil is the sum of the two potential drops.

$$V_{ab} = IR + L\frac{dI}{dt} = (3.00\,\text{A})(3.25\Omega) + (0.44\,\text{H})(3.60\,\text{A/s}) = \boxed{11.3\,\text{V}}$$

10. We use the result for inductance per unit length from Example 30-5.

$$\frac{L}{\ell} = \frac{\mu_0}{2\pi}\ln\frac{r_2}{r_1} \le 55\times10^{-9}\,\text{H/m} \quad \rightarrow \quad r_1 \ge r_2 e^{-\frac{2\pi}{\mu_0}(55\times10^{-9}\,\text{H/m})} = (0.0030\,\text{m})\,e^{-\frac{2\pi(55\times10^{-9}\,\text{H/m})}{(4\pi\times10^{-7}\,\text{T}\cdot\text{m/A})}} = 0.00228\,\text{m}$$

$$\boxed{r_1 \ge 0.0023\,\text{m}}$$

11. The self-inductance of an air-filled solenoid was determined in Example 30-3. We solve this equation for the length of the tube, using the diameter of the wire as the length per turn.

$$L = \frac{\mu_0 N^2 A}{\ell} = \mu_0 n^2 A\ell = \frac{\mu_0 A\ell}{d^2}$$

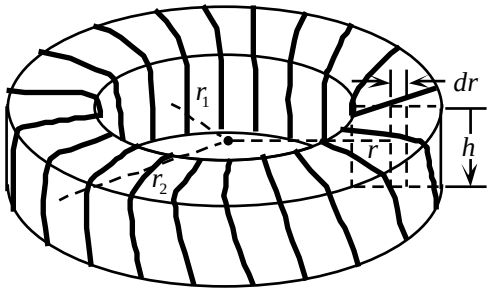
$$\ell = \frac{Ld^2}{\mu_0\pi r^2} = \frac{(1.0\,\text{H})(0.81\times10^{-3}\,\text{m})^2}{(4\pi\times10^{-7}\,\text{T}\cdot\text{m/A})\pi(0.060\,\text{m})^2} = 46.16\,\text{m} \approx \boxed{46\,\text{m}}$$

The length of the wire is equal to the number of turns (the length of the solenoid divided by the diameter of the wire) multiplied by the circumference of the turn.

$$L = \frac{\ell}{d}\pi D = \frac{46.16\,\text{m}}{0.81\times10^{-3}\,\text{m}}\pi(0.12\,\text{m}) = 21{,}490\,\text{m} \approx \boxed{21\,\text{km}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The resistance is calculated from the resistivity, area, and length of the wire.



$$R = \frac{\rho \ell}{A} = \frac{\left(1.68\times10^{-8}\,\Omega\bullet\text{m}\right)\left(21{,}490\,\text{m}\right)}{\pi\left(0.405\times10^{-3}\,\text{m}\right)^2} = \boxed{0.70\,\text{k}\Omega}$$

12. The inductance of the solenoid is given by $L = \dfrac{\mu_0 N^2 A}{\ell} = \dfrac{\mu_0 N^2}{\ell}\dfrac{\pi d^2}{4}$. The (constant) length of the wire is given by $\ell_{\text{wire}} = N\pi d_{\text{sol}}$, and so since $d_{\text{sol}\,2} = 2.5\,d_{\text{sol}\,1}$, we also know that $N_1 = 2.5N_2$. The fact that the wire is tightly wound gives $\ell_{\text{sol}} = Nd_{\text{wire}}$. Find the ratio of the two inductances.

$$\frac{L_2}{L_1} = \frac{\dfrac{\mu_0\pi}{4}\dfrac{N_2^2}{\ell_{\text{sol}\,2}}d_{\text{sol}\,2}^2}{\dfrac{\mu_0\pi}{4}\dfrac{N_1^2}{\ell_{\text{sol}\,1}}d_{\text{sol}\,1}^2} = \frac{\dfrac{N_2^2}{\ell_{\text{sol}\,2}}d_{\text{sol}\,2}^2}{\dfrac{N_1^2}{\ell_{\text{sol}\,1}}d_{\text{sol}\,1}^2} = \frac{\dfrac{\ell_{\text{wire}}^2/\pi^2}{\ell_{\text{sol}\,2}}}{\dfrac{\ell_{\text{wire}}^2/\pi^2}{\ell_{\text{sol}\,1}}} = \frac{\ell_{\text{sol}\,1}}{\ell_{\text{sol}\,2}} = \frac{N_1 d_{\text{wire}}}{N_2 d_{\text{wire}}} = \frac{N_1}{N_2} = \boxed{2.5}$$

13. We use Eq. 30-4 to calculate the self-inductance, where the flux is the integral of the magnetic field over a cross-section of the toroid. The magnetic field inside the toroid was calculated in Example 28-10.

$$L = \frac{N}{I}\Phi_B = \frac{N}{I}\int_{r_1}^{r_2}\frac{\mu_0 NI}{2\pi r}h\,dr = \boxed{\frac{\mu_0 N^2 h}{2\pi}\ln\left(\frac{r_2}{r_1}\right)}$$

14. (*a*) When connected in series the voltage drops across each inductor will add, while the currents in each inductor are the same.

$$\mathscr{E} = \mathscr{E}_1 + \mathscr{E}_2 = -L_1\frac{dI}{dt} - L_2\frac{dI}{dt} = -\left(L_1 + L_2\right)\frac{dI}{dt} = -L_{\text{eq}}\frac{dI}{dt} \quad\rightarrow\quad \boxed{L_{\text{eq}} = L_1 + L_2}$$

(*b*) When connected in parallel the currents in each inductor add to the equivalent current, while the voltage drop across each inductor is the same as the equivalent voltage drop.

$$\frac{dI}{dt} = \frac{dI_1}{dt} + \frac{dI_2}{dt} \quad\rightarrow\quad \frac{\mathscr{E}}{L_{\text{eq}}} = \frac{\mathscr{E}}{L_1} + \frac{\mathscr{E}}{L_2} \quad\rightarrow\quad \boxed{\frac{1}{L_{\text{eq}}} = \frac{1}{L_1} + \frac{1}{L_2}}$$

Therefore, inductors in series and parallel add the same as resistors in series and parallel.

15. The magnetic energy in the field is derived from Eq. 30-7.

$$u = \frac{\text{Energy stored}}{\text{Volume}} = \tfrac{1}{2}\frac{B^2}{\mu_0} \quad\rightarrow$$

$$\text{Energy} = \tfrac{1}{2}\frac{B^2}{\mu_0}\left(\text{Volume}\right) = \tfrac{1}{2}\frac{B^2}{\mu_0}\pi r^2\ell = \tfrac{1}{2}\frac{\left(0.600\,\text{T}\right)^2}{\left(4\pi\times10^{-7}\,\text{T}\bullet\text{m/A}\right)}\pi\left(0.0105\,\text{m}\right)^2\left(0.380\,\text{m}\right) = \boxed{18.9\,\text{J}}$$

16. (*a*) We use Eq. 24-6 to calculate the energy density in an electric field and Eq. 30-7 to calculate the energy density in the magnetic field.

$$u_E = \tfrac{1}{2}\varepsilon_0 E^2 = \tfrac{1}{2}\left(8.85\times10^{-12}\ \text{C}^2/\text{N}\bullet\text{m}^2\right)\left(1.0\times10^4\ \text{N/C}\right)^2 = \boxed{4.4\times10^{-4}\ \text{J/m}^3}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$u_B = \frac{B^2}{2\mu_0} = \frac{(2.0\text{ T})^2}{2(4\pi\times10^{-7}\text{ T•m/A})} = 1.592\times10^6\text{ J/m}^3 \approx \boxed{1.6\times10^6\text{ J/m}^3}$$

(*b*) Use Eq. 24-6 to calculate the electric field from the energy density for the magnetic field given in part (*a*).

$$u_E = \tfrac{1}{2}\varepsilon_0 E^2 = u_B \quad\rightarrow\quad E = \sqrt{\frac{2u_B}{\varepsilon_0}} = \sqrt{\frac{2(1.592\times10^6\text{ J/m}^3)}{(8.85\times10^{-12}\text{ C}^2/\text{N•m}^2)}} = \boxed{6.0\times10^8\text{ N/C}}$$

17. We use Eq. 30-7 to calculate the energy density with the magnetic field calculated in Example 28-12.

$$u_B = \frac{B^2}{2\mu_0} = \frac{1}{2\mu_0}\left(\frac{\mu_0 I}{2R}\right)^2 = \frac{\mu_0 I^2}{8R^2} = \frac{(4\pi\times10^{-7}\text{ T•m/A})(23.0\text{ A})^2}{8(0.280\text{ m})^2} = \boxed{1.06\times10^{-3}\text{ J/m}^3}$$

18. We use Eq. 30-7 to calculate the magnetic energy density, with the magnetic field calculated using Eq. 28-1.

$$u_B = \frac{B^2}{2\mu_0} = \frac{1}{2\mu_0}\left(\frac{\mu_0 I}{2\pi R}\right)^2 = \frac{\mu_0 I^2}{8\pi^2 R^2} = \frac{(4\pi\times10^{-7}\text{ T•m/A})(15\text{ A})^2}{8\pi^2(1.5\times10^{-3}\text{ m})^2} = \boxed{1.6\text{ J/m}^3}$$

To calculate the electric energy density with Eq. 24-6, we must first calculate the electric field at the surface of the wire. The electric field will equal the voltage difference along the wire divided by the length of the wire. We can calculate the voltage drop using Ohm's law and the resistance from the resistivity and diameter of the wire.

$$E = \frac{V}{\ell} = \frac{IR}{\ell} = \frac{I\rho\ell}{\ell\pi r^2} = \frac{I\rho}{\pi r^2}$$

$$u_E = \tfrac{1}{2}\varepsilon_0 E^2 = \tfrac{1}{2}\varepsilon_0\left(\frac{I\rho}{\pi r^2}\right)^2 = \tfrac{1}{2}(8.85\times10^{-12}\text{C}^2/\text{N•m}^2)\left[\frac{(15\text{A})(1.68\times10^{-8}\Omega\text{•m})}{\pi(1.5\times10^{-3}\text{m})^2}\right]^2$$

$$= \boxed{5.6\times10^{-15}\text{J/m}^3}$$

19. We use Eq. 30-7 to calculate the energy density in the toroid, with the magnetic field calculated in Example 28-10. We integrate the energy density over the volume of the toroid to obtain the total energy stored in the toroid. Since the energy density is a function of radius only, we treat the toroid as cylindrical shells each with differential volume $dV = 2\pi rhdr$.

$$u_B = \frac{B^2}{2\mu_0} = \frac{1}{2\mu_0}\left(\frac{\mu_0 NI}{2\pi r}\right)^2 = \boxed{\frac{\mu_0 N^2 I^2}{8\pi^2 r^2}}$$

$$U = \int u_B dV = \int_{r_1}^{r_2}\frac{\mu_0 N^2 I^2}{8\pi^2 r^2}2\pi rhdr = \frac{\mu_0 N^2 I^2 h}{4\pi}\int_{r_1}^{r_2}\frac{dr}{r} = \boxed{\frac{\mu_0 N^2 I^2 h}{4\pi}\ln\left(\frac{r_2}{r_1}\right)}$$

20. The magnetic field between the cables is given in Example 30-5. Since the magnetic field only depends on radius, we use Eq. 30-7 for the energy density in the differential volume $dV = 2\pi r\ell dr$ and integrate over the radius between the two cables.

$$\frac{U}{\ell} = \frac{1}{\ell}\int u_B dV = \int_{r_1}^{r_2}\frac{1}{2\mu_0}\left(\frac{\mu_0 I}{2\pi r}\right)^2 2\pi rdr = \frac{\mu_0 I^2}{4\pi}\int_{r_1}^{r_2}\frac{dr}{r} = \boxed{\frac{\mu_0 I^2}{4\pi}\ln\left(\frac{r_2}{r_1}\right)}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

21. We create an Amperean loop of radius *r* to calculate the magnetic field within the wire using Eq. 28-3. Since the resulting magnetic field only depends on radius, we use Eq. 30-7 for the energy density in the differential volume $dV = 2\pi r\ell dr$ and integrate from zero to the radius of the wire.

$$\oint \vec{\mathbf{B}} \bullet d\vec{\ell} = \mu_0 I_{enc} \rightarrow B(2\pi r) = \mu_0 \left(\frac{I}{\pi R^2}\right)(\pi r^2) \rightarrow B = \frac{\mu_0 I r}{2\pi R^2}$$

$$\frac{U}{\ell} = \frac{1}{\ell}\int u_B dV = \int_0^R \frac{1}{2\mu_0}\left(\frac{\mu_0 I r}{2\pi R^2}\right)^2 2\pi r dr = \frac{\mu_0 I^2}{4\pi R^4}\int_0^R r^3 dr = \boxed{\frac{\mu_0 I^2}{16\pi}}$$

22. For an *LR* circuit, we have $I = I_{\max}\left(1 - e^{-t/\tau}\right)$. Solve for t.

$$I = I_{\max}\left(1 - e^{-t/\tau}\right) \quad \rightarrow \quad e^{-t/\tau} = 1 - \frac{I}{I_{\max}} \quad \rightarrow \quad t = -\tau \ln\left(1 - \frac{I}{I_{\max}}\right)$$

(*a*) $I = 0.95 I_{\max} \quad \rightarrow \quad t = -\tau \ln\left(1 - \frac{I}{I_{\max}}\right) = -\tau \ln(1 - 0.95) = \boxed{3.0\tau}$

(*b*) $I = 0.990 I_{\max} \quad \rightarrow \quad t = -\tau \ln\left(1 - \frac{I}{I_{\max}}\right) = -\tau \ln(1 - 0.990) = \boxed{4.6\tau}$

(*c*) $I = 0.9990 I_{\max} \quad \rightarrow \quad t = -\tau \ln\left(1 - \frac{I}{I_{\max}}\right) = -\tau \ln(1 - 0.9990) = \boxed{6.9\tau}$

23. We set the current in Eq. 30-11 equal to $0.03I_0$ and solve for the time.

$$I = 0.03 I_0 = I_0 e^{-t/\tau} \rightarrow t = -\tau \ln(0.03) \approx \boxed{3.5\tau}$$

24. (*a*) We set *I* equal to 75% of the maximum value in Eq. 30-9 and solve for the time constant.

$$I = 0.75 I_0 = I_0\left(1 - e^{-t/\tau}\right) \rightarrow \tau = -\frac{t}{\ln(0.25)} = -\frac{(2.56\text{ ms})}{\ln(0.25)} = 1.847\text{ ms} \approx \boxed{1.85\text{ ms}}$$

(*b*) The resistance can be calculated from the time constant using Eq. 30-10.

$$R = \frac{L}{\tau} = \frac{31.0\text{ mH}}{1.847\text{ ms}} = \boxed{16.8\ \Omega}$$

25. (*a*) We use Eq. 30-6 to determine the energy stored in the inductor, with the current given by Eq. Eq 30-9.

$$U = \tfrac{1}{2} L I^2 = \boxed{\frac{L V_0^2}{2R^2}\left(1 - e^{-t/\tau}\right)^2}$$

(*b*) Set the energy from part (*a*) equal to 99.9% of its maximum value and solve for the time.

$$U = 0.999\frac{V_0^2}{2R^2} = \frac{V_0^2}{2R^2}\left(1 - e^{-t/\tau}\right)^2 \rightarrow t = \tau \ln\left(1 - \sqrt{0.999}\right) \approx \boxed{7.6\tau}$$

26. (*a*) At the moment the switch is closed, no current will flow through the inductor. Therefore, the resistors R_1 and R_2 can be treated as in series.

$$\mathscr{E} = I(R_1 + R_2) \rightarrow \boxed{I_1 = I_2 = \frac{\mathscr{E}}{R_1 + R_2},\ I_3 = 0}$$

(*b*) A long time after the switch is closed, there is no voltage drop across the inductor so resistors R_2 and R_3 can be treated as parallel resistors in series with R_1.

$$I_1 = I_2 + I_3, \quad \mathscr{E} = I_1R_1 + I_2R_2, \quad I_2R_2 = I_3R_3$$

$$\frac{\mathscr{E} - I_2R_2}{R_1} = I_2 + \frac{I_2R_2}{R_3} \rightarrow \boxed{I_2 = \frac{\mathscr{E}R_3}{R_2R_3 + R_1R_3 + R_1R_2}}$$

$$I_3 = \frac{I_2R_2}{R_3} = \boxed{\frac{\mathscr{E}R_2}{R_2R_3 + R_1R_3 + R_1R_2}} \qquad I_1 = I_2 + I_3 = \boxed{\frac{\mathscr{E}(R_3 + R_2)}{R_2R_3 + R_1R_3 + R_1R_2}}$$

(*c*) Just after the switch is opened the current through the inductor continues with the same magnitude and direction. With the open switch, no current can flow through the branch with the switch. Therefore the current through R_2 must be equal to the current through R_3, but in the opposite direction.

$$I_3 = \boxed{\frac{\mathscr{E}R_2}{R_2R_3 + R_1R_3 + R_1R_2}}, \quad I_2 = \boxed{\frac{-\mathscr{E}R_2}{R_2R_3 + R_1R_3 + R_1R_2}}, \quad I_1 = \boxed{0}$$

(*d*) After a long time, with no voltage source, the energy in the inductor will dissipate and no current will flow through any of the branches.

$$I_1 = I_2 = I_3 = \boxed{0}$$

27. (*a*) We use Eq. 30-5 to determine the emf in the inductor as a function of time. Since the exponential term decreases in time, the maximum emf occurs when $t = 0$.

$$\mathscr{E} = -L\frac{dI}{dt} = -L\frac{d}{dt}\left[I_0e^{-tR/L}\right] = \frac{LI_0R}{L}e^{-t/\tau} = V_0e^{-t/\tau} \rightarrow \boxed{\mathscr{E}_{\max} = V_0}.$$

(*b*) The current is the same just before and just after the switch moves from A to B. We use Ohm's law for a steady state current to determine I_0 before the switch is thrown. After the switch is thrown, the same current flows through the inductor, and therefore that current will flow through the resistor *R'*. Using Kirchhoff's loop rule we calculate the emf in the inductor. This will be a maximum at $t = 0$.

$$I_0 = \frac{V_0}{R}, \qquad \mathscr{E} - IR' = 0 \rightarrow \mathscr{E} = R'\frac{V_0}{R}e^{-t/\tau'} \rightarrow \mathscr{E}_{\max} = \left(\frac{R'}{R}\right)V_0 = \left(\frac{55R}{R}\right)(120\,\text{V}) = \boxed{6.6\,\text{kV}}$$

28. The steady state current is the voltage divided by the resistance while the time constant is the inductance divided by the resistance, Eq. 30-10. To cut the time constant in half, we must double the resistance. If the resistance is doubled, we must double the voltage to keep the steady state current constant.

$$R' = 2R = 2(2200\ \Omega) = \boxed{4400\ \Omega} \qquad V_0' = 2V_0 = 2(240\ \text{V}) = \boxed{480\ \text{V}}$$

29. We use Kirchhoff's loop rule in the steady state (no voltage drop across the inductor) to determine the current in the circuit just before the battery is removed. This will be the maximum current after the battery is removed. Again using Kirchhoff's loop rule, with the current given by Eq. 30-11, we calculate the emf as a function of time.

$$V - I_0R = 0 \ \rightarrow \ I_0 = \frac{V}{R}$$

$$\mathscr{E} - IR = 0 \ \rightarrow \ \mathscr{E} = I_0Re^{-t/\tau} = V\,\text{e}^{-tR/L} = (12\,\text{V})e^{-t(2.2\,\text{k}\Omega)/(18\,\text{mH})} = \boxed{(12\,\text{V})e^{-\left(1.22\times10^5\,\text{s}^{-1}\right)t}}$$

The emf across the inductor is greatest at $\boxed{t = 0}$ with a value of $\boxed{\mathscr{E}_{\max} = 12\,\text{V}}$.

30. We use the inductance of a solenoid, as derived in Example 30-3: $L_{\text{sol}} = \dfrac{\mu_0 N^2 A}{\ell}$.

(*a*) Both solenoids have the same area and the same length. Because the wire in solenoid 1 is 1.5 times as thick as the wire in solenoid 2, solenoid 2 will have 1.5 times the number of turns as solenoid 1.

$$\frac{L_2}{L_1} = \frac{\dfrac{\mu_0 N_2^2 A}{\ell}}{\dfrac{\mu_0 N_1^2 A}{\ell}} = \frac{N_2^2}{N_1^2} = \left(\frac{N_2}{N_1}\right)^2 = 1.5^2 = 2.25 \quad \rightarrow \quad \boxed{\frac{L_2}{L_1} = 2.25}$$

(*b*) To find the ratio of the time constants, both the inductance and resistance ratios need to be known. Since solenoid 2 has 1.5 times the number of turns as solenoid 1, the length of wire used to make solenoid 2 is 1.5 times that used to make solenoid 1, or $\ell_{\text{wire 2}} = 1.5\ell_{\text{wire 1}}$, and the diameter of the wire in solenoid 1 is 1.5 times that in solenoid 2, or $d_{\text{wire 1}} = 1.5 d_{\text{wire 2}}$. Use this to find their relative resistances, and then the ratio of time constants.

$$\frac{R_1}{R_2} = \frac{\dfrac{\rho \ell_{\text{wire 1}}}{A_{\text{wire 1}}}}{\dfrac{\rho \ell_{\text{wire 2}}}{A_{\text{wire 2}}}} = \frac{\dfrac{\ell_{\text{wire 1}}}{\pi\left(d_{\text{wire 1}}/2\right)^2}}{\dfrac{\ell_{\text{wire 2}}}{\pi\left(d_{\text{wire 2}}/2\right)^2}} = \frac{\dfrac{\ell_{\text{wire 1}}}{d_{\text{wire 1}}^2}}{\dfrac{\ell_{\text{wire 2}}}{d_{\text{wire 2}}^2}} = \frac{\ell_{\text{wire 1}}}{\ell_{\text{wire 2}}}\left(\frac{d_{\text{wire 2}}}{d_{\text{wire 1}}}\right)^2 = \left(\frac{1}{1.5}\right)\left(\frac{1}{1.5}\right)^2 = \frac{1}{1.5^3} \quad \rightarrow$$

$$\frac{R_1}{R_2} = \frac{1}{1.5^3} \quad ; \quad \frac{\tau_1}{\tau_2} = \frac{L_1/R_1}{L_2/R_2} = \frac{L_1}{L_2}\frac{R_2}{R_1} = \left(\frac{1}{2.25}\right)\left(1.5^3\right) = 1.5 \quad \rightarrow \quad \boxed{\frac{\tau_1}{\tau_2} = 1.5}$$

31. (*a*) The AM station received by the radio is the resonant frequency, given by Eq. 30-14. We divide the resonant frequencies to create an equation relating the frequencies and capacitances. We then solve this equation for the new capacitance.

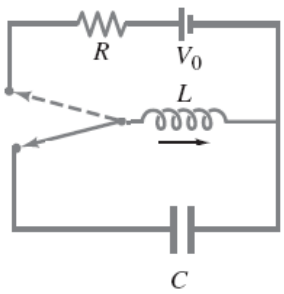
$$\frac{f_1}{f_2} = \frac{\dfrac{1}{2\pi}\sqrt{\dfrac{1}{LC_1}}}{\dfrac{1}{2\pi}\sqrt{\dfrac{1}{LC_2}}} = \sqrt{\frac{C_2}{C_1}} \rightarrow C_2 = C_1\left(\frac{f_1}{f_2}\right)^2 = (1350\,\text{pF})\left(\frac{550\,\text{kHz}}{1600\,\text{kHz}}\right)^2 = \boxed{0.16\,\text{nF}}$$

(*b*) The inductance is obtained from Eq. 30-14.

$$f = \frac{1}{2\pi}\sqrt{\frac{1}{LC_1}} \rightarrow L = \frac{1}{4\pi^2 f^2 C} = \frac{1}{4\pi^2\left(550\times10^3\,\text{Hz}\right)^2\left(1350\times10^{-12}\,\text{F}\right)} = \boxed{62\,\mu\text{H}}$$

32. (*a*) To have maximum current and no charge at the initial time, we set $t = 0$ in Eqs. 30-13 and 30-15 to solve for the necessary phase factor ϕ.

$$I_0 = I_0 \sin\phi \rightarrow \phi = \frac{\pi}{2} \rightarrow I(t) = I_0 \sin\left(\omega t + \frac{\pi}{2}\right) = I_0 \cos\omega t$$



$$Q(0) = Q_0 \cos\left(\frac{\pi}{2}\right) = 0 \rightarrow Q = Q_0 \cos\left(\omega t + \frac{\pi}{2}\right) = -Q_0 \sin\left(\omega t\right)$$

Differentiating the charge with respect to time gives the negative of the current. We use this to write the charge in terms of the known maximum current.

$$I = -\frac{dQ}{dt} = -Q_0\omega\cos\left(\omega t\right) = I_0\cos\left(\omega t\right) \quad \rightarrow \quad Q_0 = \frac{I_0}{\omega} \quad \rightarrow \quad \boxed{Q(t) = \frac{I_0}{\omega}\sin\left(\omega t\right)}$$

(*b*) As in the figure, attach the inductor to a battery and resistor for an extended period so that a steady state current flows through the inductor. Then at time $t = 0$, flip the switch connecting the inductor in series to the capacitor.

33. (*a*) We write the oscillation frequency in terms of the capacitance using Eq. 30-14, with the parallel plate capacitance given by Eq. 24-2. We then solve the resulting equation for the plate separation distance.

$$2\pi f = \sqrt{\frac{1}{LC}} = \sqrt{\frac{1}{L(\varepsilon_0 A/x)}} \rightarrow x = \boxed{4\pi^2 A\varepsilon_0 f^2 L}$$

(*b*) For small variations we can differentiate x and divide the result by x to determine the fractional change.

$$dx = 4\pi^2 A\varepsilon_0 (2\,fdf)L \;\; ; \;\; \frac{dx}{x} = \frac{4\pi^2 A\varepsilon_0 (2\,fdf)L}{4\pi^2 A\varepsilon_0 f^2 L} = \frac{2df}{f} \rightarrow \boxed{\frac{\Delta x}{x} \approx \frac{2\Delta f}{f}}$$

(*c*) Inserting the given data, we can calculate the fractional variation on x.

$$\frac{\Delta x}{x} \approx \frac{2(1\text{ Hz})}{1\text{ MHz}} = 2\times 10^{-6} = \boxed{0.0002\%}$$

34. (*a*) We calculate the resonant frequency using Eq. 30-14.

$$f = \frac{1}{2\pi}\sqrt{\frac{1}{LC}} = \frac{1}{2\pi}\sqrt{\frac{1}{(0.175\text{ H})(425\times 10^{-12}\text{ F})}} = 18{,}450\text{ Hz} \approx \boxed{18.5\text{ kHz}}$$

(*b*) As shown in Eq. 30-15, we set the peak current equal to the maximum charge (from Eq. 24-1) multiplied by the angular frequency.

$$I = Q_0\omega = CV(2\pi f) = (425\times 10^{-12}\text{ F})(135\text{ V})(2\pi)(18{,}450\text{ Hz})$$

$$= 6.653\times 10^{-3}\text{ A} \approx \boxed{6.65\text{ mA}}$$

(*c*) We use Eq. 30-6 to calculate the maximum energy stored in the inductor.

$$U = \tfrac{1}{2}LI^2 = \tfrac{1}{2}(0.175\text{ H})(6.653\times 10^{-3}\text{ A})^2 = \boxed{3.87\ \mu\text{J}}$$

35. (*a*) When the energy is equally shared between the capacitor and inductor, the energy stored in the capacitor will be one half of the initial energy in the capacitor. We use Eq. 24-5 to write the energy in terms of the charge on the capacitor and solve for the charge when the energy is equally shared.

$$\frac{Q^2}{2C} = \frac{1}{2}\frac{Q_0^2}{2C} \rightarrow Q = \boxed{\frac{\sqrt{2}}{2}Q_0}$$

(*b*) We insert the charge into Eq. 30-13 and solve for the time.

$$\frac{\sqrt{2}}{2}Q_0 = Q_0\cos\omega t \rightarrow t = \frac{1}{\omega}\cos^{-1}\left(\frac{\sqrt{2}}{2}\right) = \frac{T}{2\pi}\left(\frac{\pi}{4}\right) = \boxed{\frac{T}{8}}$$

36. Since the circuit loses 3.5% of its energy per cycle, it is an underdamped oscillation. We use Eq. 24-5 for the energy with the charge as a function of time given by Eq. 30-19. Setting the change in energy equal to 3.5% and using Eq. 30-18 to determine the period, we solve for the resistance.

$$\frac{\Delta E}{E} = \frac{\dfrac{Q_0^2 e^{-\frac{R}{L}T}\cos^2(2\pi)}{2C} - \dfrac{Q_0^2\cos^2(0)}{2C}}{\dfrac{Q_0^2\cos^2(0)}{2C}} = e^{-\frac{R}{L}T} - 1 = -0.035 \rightarrow \frac{RT}{L} = \ln(1-0.035) = 0.03563$$

$$0.03563 = \frac{R}{L}\left(\frac{2\pi}{\omega'}\right) = \frac{R}{L}\frac{2\pi}{\sqrt{1/LC - R^2/4L^2}} \rightarrow R = \sqrt{\frac{4L(0.03563)^2}{C\left[16\pi^2 + (0.03563)^2\right]}}$$

$$R = \sqrt{\frac{4(0.065\,\text{H})(0.03563)^2}{(1.00\times10^{-6}\,\text{F})\left[16\pi^2 + (0.03563)^2\right]}} = 1.4457\,\Omega \approx \boxed{1.4\,\Omega}$$

37. As in the derivation of 30-16, we set the total energy equal to the sum of the magnetic and electric energies, with the charge given by Eq. 30-19. We then solve for the time that the energy is 75% of the initial energy.

$$U = U_E + U_B = \frac{Q^2}{2C} + \frac{LI^2}{2} = \frac{Q_0^2}{2C}e^{-\frac{R}{L}t}\cos^2(\omega' t + \phi) + \frac{Q_0^2}{2C}e^{-\frac{R}{L}t}\sin^2(\omega' t + \phi) = \frac{Q_0^2}{2C}e^{-\frac{R}{L}t}$$

$$0.75\frac{Q_0^2}{2C} = \frac{Q_0^2}{2C}e^{-\frac{R}{L}t} \rightarrow t = -\frac{L}{R}\ln(0.75) = -\frac{L}{R}\ln(0.75) \approx \boxed{0.29\frac{L}{R}}$$

38. As shown by Eq. 30-18, adding resistance will decrease the oscillation frequency. We use Eq. 30-14 for the pure LC circuit frequency and Eq. 30-18 for the frequency with added resistance to solve for the resistance.

$$\omega' = (1-.0025)\omega \quad \rightarrow \quad \sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}} = 0.9975\sqrt{\frac{1}{LC}} \quad \rightarrow$$

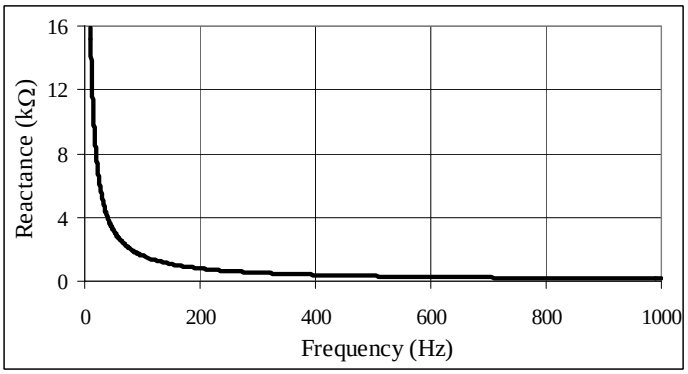
$$R = \sqrt{\frac{4L}{C}\left(1-0.9975^2\right)} = \sqrt{\frac{4(0.350\,\text{H})}{(1.800\times10^{-9}\,\text{F})}\left(1-0.9975^2\right)} = \boxed{2.0\,\text{k}\Omega}$$

39. We find the frequency from Eq. 30-23b for the reactance of an inductor.

$$X_L = 2\pi fL \quad \rightarrow \quad f = \frac{X_L}{2\pi L} = \frac{660\,\Omega}{2\pi(0.0320\,\text{H})} = 3283\,\text{Hz} \approx \boxed{3300\,\text{Hz}}$$

40. The reactance of a capacitor is given by Eq. 30-25b, $X_C = \dfrac{1}{2\pi fC}$.

(*a*) $X_C = \dfrac{1}{2\pi fC} = \dfrac{1}{2\pi(60.0\,\text{Hz})(9.2\times10^{-6}\,\text{F})} = \boxed{290\,\Omega}$



(*b*) $X_C = \dfrac{1}{2\pi fC} = \dfrac{1}{2\pi(1.00\times10^{6}\,\text{Hz})(9.2\times10^{-6}\,\text{F})} = \boxed{1.7\times10^{-2}\,\Omega}$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41. The impedance is $X_C = \dfrac{1}{2\pi fC}$. The extreme values are as follows.

$$X_{\max} = \frac{1}{2\pi(10\,\text{Hz})(1.0\times10^{-6}\,\text{F})} = 16{,}000\,\Omega$$

$$X_{\min} = \frac{1}{2\pi(1000\,\text{Hz})(1.0\times10^{-6}\,\text{F})} = 160\,\Omega$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH30.XLS," on tab "Problem 30.41."

42. We find the reactance from Eq. 30-23b, and the current from Ohm's law.

$$X_L = 2\pi fL = 2\pi(33.3\times10^{3}\,\text{Hz})(0.0360\,\text{H}) = 7532\,\Omega \approx \boxed{7530\,\Omega}$$

$$V = IX_L \;\rightarrow\; I = \frac{V}{X_L} = \frac{250\,\text{V}}{7532\,\Omega} = 0.03319\,\text{A} \approx \boxed{3.3\times10^{-2}\,\text{A}}$$

43. (*a*) At $\omega = 0$, the impedance of the capacitor is infinite. Therefore the parallel combination of the resistor *R* and capacitor *C* behaves as the resistor only, and so is *R*. Thus the impedance of the entire circuit is equal to the resistance of the two series resistors.

$$Z = \boxed{R + R'}$$

(*b*) At $\omega = \infty,$, the impedance of the capacitor is zero. Therefore the parallel combination of the resistor *R* and capacitor *C* is equal to zero. Thus the impedance of the entire circuit is equal to the resistance of the series resistor only.

$$Z = \boxed{R'}$$

44. We use Eq. 30-22a to solve for the impedance.

$$V_{\text{rms}} = I_{\text{rms}}\omega L \rightarrow L = \frac{V_{\text{rms}}}{I_{\text{rms}}\omega} = \frac{110\,\text{V}}{(3.1\,\text{A})2\pi(60\,\text{Hz})} = \boxed{94\,\text{mH}}$$

45. (*a*) We find the reactance from Eq. 30-25b.

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(660\,\text{Hz})(8.6\times10^{-8}\,\text{F})} = 2804\,\Omega \approx \boxed{2800\,\Omega}$$

(*b*) We find the peak value of the current from Ohm's law.

$$I_{\text{peak}} = \sqrt{2}I_{\text{rms}} = \sqrt{2}\frac{V_{\text{rms}}}{X_C} = \sqrt{2}\frac{22{,}000\,\text{V}}{2804\,\Omega} = \boxed{11\,\text{A at }660\,\text{Hz}}$$

46. (*a*) Since the resistor and capacitor are in parallel, they will have the same voltage drop across them. We use Ohm's law to determine the current through the resistor and Eq. 30-25 to determine the current across the capacitor. The total current is the sum of the currents across each element.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_R = \frac{V}{R} \;;\; I_C = \frac{V}{X_C} = V(2\pi fC)$$

$$\frac{I_C}{I_R + I_C} = \frac{V(2\pi fC)}{V(2\pi fC) + V/R} = \frac{R(2\pi fC)}{R(2\pi fC)+1} = \frac{(490\ \Omega)2\pi(60\ \text{Hz})(0.35\times10^{-6}\ \text{F})}{(490\ \Omega)2\pi(60\ \text{Hz})(0.35\times10^{-6}\ \text{F})+1}$$

$$= 0.0607 \approx \boxed{6.1\%}$$

(*b*) We repeat part (*a*) with a frequency of 60,000 Hz.

$$\frac{I_C}{I_R + I_C} = \frac{(490\ \Omega)2\pi(60{,}000\ \text{Hz})(0.35\times10^{-6}\ \text{F})}{(490\ \Omega)2\pi(60{,}000\ \text{Hz})(0.35\times10^{-6}\ \text{F})+1} = 0.9847 \approx \boxed{98\%}$$

47. The power is only dissipated in the resistor, so we use the power dissipation equation obtained in section 25-7.

$$P_{\text{avg}} = \tfrac{1}{2} I_0^2 R = \tfrac{1}{2}(1.80\,\text{A})^2(1350\,\Omega) = 2187\,\text{W} \approx \boxed{2.19\,\text{kW}}$$

48. The impedance of the circuit is given by Eq. 30-28a without a capacitive reactance. The reactance of the inductor is given by Eq. 30-23b.

(*a*) $$Z = \sqrt{R^2 + X_L^2} = \sqrt{R^2 + 4\pi^2 f^2 L^2} = \sqrt{(10.0\times10^3\,\Omega)^2 + 4\pi^2(55.0\,\text{Hz})^2(0.0260\,\text{H})^2}$$

$$= \boxed{1.00\times10^4\,\Omega}$$

(*b*) $$Z = \sqrt{R^2 + X_L^2} = \sqrt{R^2 + 4\pi^2 f^2 L^2} = \sqrt{(10.0\times10^3\,\Omega)^2 + 4\pi^2(5.5\times10^4\,\text{Hz})^2(0.0260\,\text{H})^2}$$

$$= \boxed{1.34\times10^4\,\Omega}$$

49. The impedance of the circuit is given by Eq. 30-28a without an inductive reactance. The reactance of the capacitor is given by Eq. 30-25b.

(*a*) $$Z = \sqrt{R^2 + X_C^2} = \sqrt{R^2 + \frac{1}{4\pi^2 f^2 C^2}} = \sqrt{(75\Omega)^2 + \frac{1}{4\pi^2(60\,\text{Hz})^2(6.8\times10^{-6}\,\text{F})^2}} = 397\,\Omega$$

$$\approx \boxed{400\,\Omega}\,(2\text{ sig. fig.})$$

(*b*) $$Z = \sqrt{R^2 + X_C^2} = \sqrt{R^2 + \frac{1}{4\pi^2 f^2 C^2}} = \sqrt{(75\Omega)^2 + \frac{1}{4\pi^2(60000\,\text{Hz})^2(6.8\times10^{-6}\,\text{F})^2}} = \boxed{75\,\Omega}$$

50. We find the impedance from Eq. 30-27.

$$Z = \frac{V_{\text{rms}}}{I_{\text{rms}}} = \frac{120\,\text{V}}{70\times10^{-3}\,\text{A}} = \boxed{1700\,\Omega}$$

51. The impedance is given by Eq. 30-28a with no capacitive reactance.

$$Z = \sqrt{R^2 + X_L^2} = \sqrt{R^2 + (2\pi fL)^2}$$

$$Z_f = 2Z_{60} \;\rightarrow\; \sqrt{R^2 + 4\pi^2 f^2 L^2} = 2\sqrt{R^2 + 4\pi^2(60\,\text{Hz})^2 L^2} \;\rightarrow$$

$$R^2 + 4\pi^2 f^2 L^2 = 4\left[R^2 + 4\pi^2(60\,\text{Hz})^2 L^2\right] = 4R^2 + 16\pi^2(60\,\text{Hz})^2 L^2 \;\rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$f = \sqrt{\frac{3R^2 + 16\pi^2 (60\,\text{Hz})^2 L^2}{4\pi^2 L^2}} = \sqrt{\frac{3R^2}{4\pi^2 L^2} + 4(60\,\text{Hz})^2} = \sqrt{\frac{3(2500\,\Omega)^2}{4\pi^2 (0.42\,\text{H})^2} + 4(60\,\text{Hz})^2}$$

$$= 1645\,\text{Hz} \approx \boxed{1.6\,\text{kHz}}$$

52. (*a*) The rms current is the rmv voltage divided by the impedance. The impedance is given by Eq. 30-28a with no inductive reactance,

$$Z = \sqrt{R^2 + X_C^2} = \sqrt{R^2 + \frac{1}{(2\pi fC)^2}}\ .$$

$$I_{\text{rms}} = \frac{V_{\text{rms}}}{Z} = \frac{V_{\text{rms}}}{\sqrt{R^2 + \dfrac{1}{4\pi^2 f^2 L^2}}} = \frac{120\,\text{V}}{\sqrt{(3800\,\Omega)^2 + \dfrac{1}{4\pi^2 (60.0\,\text{Hz})^2 (0.80\times10^{-6}\,\text{F})^2}}}$$

$$= \frac{120\,\text{V}}{5043\,\Omega} = 2.379\times10^{-2}\,\text{A} \approx \boxed{2.4\times10^{-2}\,\text{A}}$$

(*b*) The phase angle is given by Eq. 30-29a with no inductive reactance.

$$\phi = \tan^{-1}\frac{-X_C}{R} = \tan^{-1}\frac{-\dfrac{1}{2\pi fC}}{R} = \tan^{-1}\frac{-\dfrac{1}{2\pi(60.0\,\text{Hz})(0.80\times10^{-6}\,\text{F})}}{3800\,\Omega} = \boxed{-41°}$$

The current is leading the source voltage.

(*c*) The power dissipated is given by $P = I_{\text{rms}}^2 R = (0.02379\,\text{A})^2 (6.0\times10^3\,\Omega) = \boxed{2.2\,\text{W}}$

(*d*) The rms voltage reading is the rms current times the resistance or reactance of the element.

$$V_{\underset{R}{\text{rms}}} = I_{\text{rms}} R = (2.379\times10^{-2}\,\text{A})(3800\,\Omega) = 90.4\,\text{V} \approx \boxed{90\,\text{V}} \quad (2\text{ sig. fig.})$$

$$V_{\underset{C}{\text{rms}}} = I_{\text{rms}} X_C = \frac{I_{\text{rms}}}{2\pi fC} = \frac{(2.379\times10^{-2}\,\text{A})}{2\pi(60.0\,\text{Hz})(0.80\times10^{-6}\,\text{F})} = 78.88\,\text{V} \approx \boxed{79\,\text{V}}$$

Note that, because the maximum voltages occur at different times, the two readings do not add to the applied voltage of 120 V.

53. We use the rms voltage across the resistor to determine the rms current through the circuit. Then, using the rms current and the rms voltage across the capacitor in Eq. 30-25 we determine the frequency.

$$I_{\text{rms}} = \frac{V_{R,\text{rms}}}{R} \qquad V_{C,\text{rms}} = \frac{I_{\text{rms}}}{2\pi fC}$$

$$f = \frac{I_{\text{rms}}}{2\pi C V_{C,\text{rms}}} = \frac{V_{R,\text{rms}}}{2\pi CR V_{C,\text{rms}}} = \frac{(3.0\text{ V})}{2\pi(1.0\times10^{-6}\text{ C})(750\ \Omega)(2.7\text{ V})} = \boxed{240\text{ Hz}}$$

Since the voltages in the resistor and capacitor are not in phase, the rms voltage across the power source will not be the sum of their rms voltages.

54. The total impedance is given by Eq. 30-28a.

$$Z = \sqrt{R^2 + \left(X_L - X_C\right)^2} = \sqrt{R^2 + \left(2\pi fL - \frac{1}{2\pi fC}\right)^2}$$

$$= \sqrt{\left(8.70\times10^3\,\Omega\right)^2 + \left[2\pi\left(1.00\times10^4\,\text{Hz}\right)\left(3.20\times10^{-2}\,\text{H}\right) - \frac{1}{2\pi\left(1.00\times10^4\,\text{Hz}\right)\left(6.25\times10^{-9}\,\text{F}\right)}\right]^2}$$

$$= 8716.5\,\Omega \approx \boxed{8.72\,\text{k}\Omega}$$

The phase angle is given by Eq. 30-29a.

$$\phi = \tan^{-1}\frac{X_L - X_C}{R} = \tan^{-1}\frac{2\pi fL - \dfrac{1}{2\pi fC}}{R}$$

$$= \tan^{-1}\frac{2\pi\left(1.00\times10^4\,\text{Hz}\right)\left(3.20\times10^{-2}\,\text{H}\right) - \dfrac{1}{2\pi\left(1.00\times10^4\,\text{Hz}\right)\left(6.25\times10^{-9}\,\text{F}\right)}}{R}$$

$$= \tan^{-1}\frac{-535.9\,\Omega}{8.70\times10^3\,\Omega} = \boxed{-3.52^\circ}$$

The voltage is lagging the current, or the current is leading the voltage.
The rms current is given by Eq. 30-27.

$$I_{\text{rms}} = \frac{V_{\text{rms}}}{\text{Z}} = \frac{725\,\text{V}}{8716.5\,\Omega} = \boxed{8.32\times10^{-2}\,\text{A}}$$

55. (*a*) The rms current is the rms voltage divided by the impedance. The impedance is given by Eq. 30-28a with no capacitive reactance.

$$Z = \sqrt{R^2 + X_L^2} = \sqrt{R^2 + \left(2\pi fL\right)^2}\ .$$

$$I_{\text{rms}} = \frac{V_{\text{rms}}}{Z} = \frac{V_{\text{rms}}}{\sqrt{R^2 + 4\pi^2 f^2 L^2}} = \frac{120\,\text{V}}{\sqrt{\left(965\,\Omega\right)^2 + 4\pi^2\left(60.0\,\text{Hz}\right)^2\left(0.225\,\text{H}\right)^2}}$$

$$= \frac{120\,\text{V}}{968.7\,\Omega} = \boxed{0.124\,\text{A}}$$

(*b*) The phase angle is given by Eq. 30-29a with no capacitive reactance.

$$\phi = \tan^{-1}\frac{X_L}{R} = \tan^{-1}\frac{2\pi fL}{R} = \tan^{-1}\frac{2\pi\left(60.0\,\text{Hz}\right)\left(0.225\,\text{H}\right)}{965\,\Omega} = \boxed{5.02^\circ}$$

The current is lagging the source voltage.

(*c*) The power dissipated is given by $P = I_{\text{rms}}^2 R = \left(0.124\,\text{A}\right)^2\left(965\,\Omega\right) = \boxed{14.8\,\text{W}}$

(*d*) The rms voltage reading is the rms current times the resistance or reactance of the element.

$$V_{\underset{R}{\text{rms}}} = I_{\text{rms}}R = \left(0.124\,\text{A}\right)\left(965\,\Omega\right) = 119.7\,\text{V} \approx \boxed{120\,\text{V}}$$

$$V_{\underset{L}{\text{rms}}} = I_{\text{rms}}X_L = I_{\text{rms}}2\pi fL = \left(0.124\,\text{A}\right)2\pi\left(60.0\,\text{Hz}\right)\left(0.25\,\text{H}\right) = \boxed{10.5\,\text{V}}$$

Note that, because the maximum voltages occur at different times, the two readings do not add to the applied voltage of 120 V.

56. (*a*) The current is found from the voltage and impedance. The impedance is given by Eq. 30-28a.

$$Z = \sqrt{R^2 + \left(X_L - X_C\right)^2} = \sqrt{R^2 + \left(2\pi fL - \frac{1}{2\pi fC}\right)^2}$$

$$= \sqrt{\left(2.0\,\Omega\right)^2 + \left[2\pi\left(60\,\text{Hz}\right)\left(0.035\,\text{H}\right) - \frac{1}{2\pi\left(60\,\text{Hz}\right)\left(26\times10^{-6}\,\text{F}\right)}\right]^2} = 88.85\,\Omega$$

$$I_{\text{rms}} = \frac{V_{\text{rms}}}{Z} = \frac{45\,\text{V}}{88.85\,\Omega} = 0.5065\,\text{A} \approx \boxed{0.51\,\text{A}}$$

(*b*) Use Eq. 30-29a to find the phase angle.

$$\phi = \tan^{-1}\frac{X_L - X_C}{R} = \tan^{-1}\frac{2\pi fL - \dfrac{1}{2\pi fC}}{R}$$

$$= \tan^{-1}\frac{2\pi\left(60\,\text{Hz}\right)\left(0.035\,\text{H}\right) - \dfrac{1}{2\pi\left(60\,\text{Hz}\right)\left(26\times10^{-6}\,\text{F}\right)}}{2.0\,\Omega} = \tan^{-1}\frac{-88.83\,\Omega}{2.0\,\Omega} = \boxed{-88°}$$

(*c*) The power dissipated is given by $P = I_{\text{rms}}^2 R = \left(0.5065\,\text{A}\right)^2\left(2.0\,\Omega\right) = \boxed{0.51\,\text{W}}$

57. For the current and voltage to be in phase, the reactances of the capacitor and inductor must be equal. Setting the two reactances equal enables us to solve for the capacitance.

$$X_L = 2\pi fL = X_C = \frac{1}{2\pi fC} \rightarrow C = \frac{1}{4\pi^2 f^2 L} = \frac{1}{4\pi^2\left(360\,\text{Hz}\right)^2\left(0.025\,\text{H}\right)} = \boxed{7.8\,\mu\text{F}}$$

58. The light bulb acts like a resistor in series with the inductor. Using the desired rms voltage across the resistor and the power dissipated by the light bulb we calculate the rms current in the circuit and the resistance. Then using this current and the rms voltage of the circuit we calculate the impedance of the circuit (Eq. 30-27) and the required inductance (Eq. 30-28b).

$$I_{\text{rms}} = \frac{P}{V_{R,\text{rms}}} = \frac{75\,\text{W}}{120\,\text{V}} = 0.625\,\text{A} \qquad R = \frac{V_{R,\text{rms}}}{I_{\text{rms}}} = \frac{120\,\text{V}}{0.625\,\text{A}} = 192\,\Omega$$

$$Z = \frac{V_{\text{rms}}}{I_{\text{rms}}} = \sqrt{R^2 + \left(2\pi fL\right)^2}$$

$$L = \frac{1}{2\pi f}\sqrt{\left(\frac{V_{\text{rms}}}{I_{\text{rms}}}\right)^2 - R^2} = \frac{1}{2\pi\left(60\ \text{Hz}\right)}\sqrt{\left(\frac{240\ \text{V}}{0.625\ \text{A}}\right)^2 - \left(192\ \Omega\right)^2} = \boxed{0.88\ \text{H}}$$

59. We multiply the instantaneous current by the instantaneous voltage to calculate the instantaneous power. Then using the trigonometric identity for the summation of sine arguments (inside back cover of text) we can simplify the result. We integrate the power over a full period and divide the result by the period to calculate the average power.

$$P = IV = \left(I_0 \sin\omega t\right)V_0 \sin\left(\omega t + \phi\right) = I_0 V_0 \sin\omega t\left(\sin\omega t\cos\phi + \sin\phi\cos\omega t\right)$$

$$= I_0 V_0\left(\sin^2\omega t\cos\phi + \sin\omega t\cos\omega t\sin\phi\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\bar{P} = \frac{1}{T}\int_0^T P dT = \frac{\omega}{2\pi}\int_0^{\frac{2\pi}{\omega}} I_0 V_0 \left(\sin^2 \omega t \cos\phi + \sin\omega t \cos\omega t \sin\phi\right) dt$$

$$= \frac{\omega}{2\pi} I_0 V_0 \cos\phi \int_0^{\frac{2\pi}{\omega}} \sin^2 \omega t \; dt + \frac{\omega}{2\pi} I_0 V_0 \sin\phi \int_0^{\frac{2\pi}{\omega}} \sin\omega t \cos\omega t \; dt$$

$$= \frac{\omega}{2\pi} I_0 V_0 \cos\phi \left(\frac{1}{2}\frac{2\pi}{\omega}\right) + \frac{\omega}{2\pi} I_0 V_0 \sin\phi \left(\frac{1}{\omega}\sin^2 \omega t\Big|_0^{\frac{2\pi}{\omega}}\right) = \boxed{\tfrac{1}{2} I_0 V_0 \cos\phi}$$

60. Given the resistance, inductance, capacitance, and frequency, we calculate the impedance of the circuit using Eq. 30-28b.

$$X_L = 2\pi fL = 2\pi\left(660 \text{ Hz}\right)\left(0.025 \text{ H}\right) = 103.67 \ \Omega$$

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi\left(660 \text{ Hz}\right)\left(2.0\times10^{-6} \text{ F}\right)} = 120.57 \ \Omega$$

$$Z = \sqrt{R^2 + \left(X_L - X_C\right)^2} = \sqrt{\left(150 \ \Omega\right)^2 + \left(103.67 \ \Omega - 120.57 \ \Omega\right)^2} = 150.95 \ \Omega$$

(*a*) From the impedance and the peak voltage we calculate the peak current, using Eq. 30-27.

$$I_0 = \frac{V_0}{Z} = \frac{340 \text{ V}}{150.95 \ \Omega} = 2.252 \text{ A} \approx \boxed{2.3 \text{ A}}$$

(*b*) We calculate the phase angle of the current from the source voltage using Eq. 30-29a.

$$\phi = \tan^{-1}\frac{X_L - X_C}{R} = \tan^{-1}\frac{103.67 \ \Omega - 120.57 \ \Omega}{150 \ \Omega} = \boxed{-6.4°}$$

(*c*) We multiply the peak current times the resistance to obtain the peak voltage across the resistor. The voltage across the resistor is in phase with the current, so the phase angle is the same as in part (*b*).

$$V_{0,R} = I_0 R = \left(2.252 \text{ A}\right)\left(150 \ \Omega\right) = \boxed{340 \text{ V}} \ ; \ \boxed{\phi = -6.4°}$$

(*d*) We multiply the peak current times the inductive reactance to calculate the peak voltage across the inductor. The voltage in the inductor is 90º ahead of the current. Subtracting the phase difference between the current and source from the 90º between the current and inductor peak voltage gives the phase angle between the source voltage and the inductive peak voltage.

$$V_{0,L} = I_0 X_L = \left(2.252 \text{ A}\right)\left(103.67 \ \Omega\right) = \boxed{230 \text{ V}}$$

$$\phi_L = 90.0° - \phi = 90.0° - \left(-6.4\right)° = \boxed{96.4°}$$

(*e*) We multiply the peak current times the capacitive reactance to calculate the peak voltage across the capacitor. Subtracting the phase difference between the current and source from the -90º between the current and capacitor peak voltage gives the phase angle between the source voltage and the capacitor peak voltage.

$$V_{0,C} = I_0 X_C = \left(2.252 \text{ A}\right)\left(120.57 \ \Omega\right) = \boxed{270 \text{ V}}$$

$$\phi_C = -90.0° - \phi = -90.0° - \left(-6.4°\right) = \boxed{-83.6°}$$

61. Using Eq. 30-23b we calculate the impedance of the inductor. Then we set the phase shift in Eq. 30-29a equal to 25º and solve for the resistance. We calculate the output voltage by multiplying the current through the circuit, from Eq. 30-27, by the inductive reactance (Eq. 30-23b).

$$X_L = 2\pi fL = 2\pi\left(175 \text{ Hz}\right)\left(0.055 \text{ H}\right) = 60.48 \ \Omega$$

$$\tan\phi = \frac{X_L}{R} \rightarrow R = \frac{X_L}{\tan\phi} = \frac{60.48 \ \Omega}{\tan 25°} = 129.7 \Omega \approx \boxed{130 \ \Omega}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{V_{\text{output}}}{V_0} = \frac{V_R}{V_0} = \frac{IR}{IZ} = \frac{R}{Z} = \frac{129.70\,\Omega}{\sqrt{(129.70\,\Omega)^2 + (60.48\,\Omega)^2}} = \boxed{0.91}$$

62. The resonant frequency is found from Eq. 30-32. The resistance does not influence the resonant frequency.

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{1}{LC}} = \frac{1}{2\pi}\sqrt{\frac{1}{(26.0\times10^{-6}\,\text{H})(3800\times10^{-12}\,\text{F})}} = \boxed{5.1\times10^5\,\text{Hz}}$$

63. We calculate the resonant frequency using Eq. 30-32 with the inductance and capacitance given in the example. We use Eq. 30-30 to calculate the power dissipation, with the impedance equal to the resistance.

$$f_0 = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(0.0300\text{ H})(12.0\times10^{-6}\text{ F})}} = \boxed{265\text{ Hz}}$$

$$\bar{P} = I_{\text{rms}}V_{\text{rms}}\cos\phi = \left(\frac{V_{\text{rms}}}{R}\right)V_{\text{rms}}\left(\frac{R}{R}\right) = \frac{V^2_{\text{rms}}}{R} = \frac{(90.0\,\text{V})^2}{25.0\,\Omega} = \boxed{324\,\text{W}}$$

64. (*a*) We find the capacitance from the resonant frequency, Eq. 30-32.

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{1}{LC}} \quad\rightarrow\quad C = \frac{1}{4\pi^2 L f_0^2} = \frac{1}{4\pi^2(4.15\times10^{-3}\,\text{H})(33.0\times10^3\,\text{Hz})^2} = \boxed{5.60\times10^{-9}\,\text{F}}$$

(*b*) At resonance the impedance is the resistance, so the current is given by Ohm's law.

$$I_{\text{peak}} = \frac{V_{\text{peak}}}{R} = \frac{136\,\text{V}}{3800\,\Omega} = \boxed{35.8\,\text{mA}}$$

65. (*a*) The peak voltage across the capacitor is the peak current multiplied by the capacitive reactance. We calculate the current in the circuit by dividing the source voltage by the impedance, where at resonance the impedance is equal to the resistance.

$$V_{C0} = X_C I_0 = \frac{1}{2\pi f_0 C}\frac{V_0}{R} = \frac{V_0}{2\pi(RC)}\frac{1}{f_0} = \boxed{\frac{V_0}{2\pi\tau}T_0}$$

(*b*) We set the amplification equal to 125 and solve for the resistance.

$$\beta = \frac{T_0}{2\pi\tau} = \frac{1}{2\pi f_0 RC} \rightarrow R = \frac{1}{2\pi f_0\beta C} = \frac{1}{2\pi(5000\,\text{Hz})(125)(2.0\times10^{-9}\,\text{F})} = \boxed{130\,\Omega}$$

66. (*a*) We calculate the resonance frequency from the inductance and capacitance using Eq.30-32.

$$f_0 = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(0.055\text{ H})(1.0\times10^{-9}\text{ F})}} = 21460\text{ Hz} \approx \boxed{21\text{ kHz}}$$

(*b*) We use the result of Problem 65 to calculate the voltage across the capacitor.

$$V_{C0} = \frac{V_0}{2\pi(RC)}\frac{1}{f_0} = \frac{2.0\text{ V}}{2\pi(35\,\Omega)(1.0\times10^{-9}\text{ F})(21460\text{ Hz})} = \boxed{420\text{ V}}$$

(*c*) We divide the voltage across the capacitor by the voltage source.

$$\frac{V_{C0}}{V_0} = \frac{420\text{ V}}{2.0\text{ V}} = \boxed{210}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

67. (*a*) We write the average power using Eq. 30-30, with the current in terms of the impedance (Eq. 30-27) and the power factor in terms of the resistance and impedance (Eq. 30-29b). Finally we write the impedance using Eq. 30-28b.

$$\bar{P} = I_{\text{rms}} V_{\text{rms}} \cos\phi = \frac{V_{\text{rms}}}{Z} V_{\text{rms}} \frac{R}{Z} = \frac{V_{\text{rms}}^2 R}{Z^2} = \boxed{\frac{V_0^2 R}{2\left[R^2 + \left(\omega L - 1/\omega C\right)^2\right]}}$$

(*b*) The power dissipation will be a maximum when the inductive reactance is equal to the capacitive reactance, which is the resonant frequency.

$$f = \boxed{\frac{1}{2\pi\sqrt{LC}}}$$

(*c*) We set the power dissipation equal to ½ of the maximum power dissipation and solve for the angular frequencies.

$$\bar{P} = \frac{1}{2}\bar{P}_{\max} = \frac{V_0^2 R}{2\left[R^2 + \left(\omega L - 1/\omega C\right)^2\right]} = \frac{1}{2}\left(\frac{V_0^2 R}{2R^2}\right) \rightarrow \left(\omega L - 1/\omega C\right) = \pm R$$

$$\rightarrow\ 0 = \omega^2 LC \pm RC\omega - 1 \ \rightarrow\ \omega = \frac{\pm RC \pm \sqrt{R^2C^2 + 4LC}}{2LC}$$

We require the angular frequencies to be positive and for a sharp peak, $R^2C^2 \ll 4LC$. The angular width will then be the difference between the two positive frequencies.

$$\omega = \frac{2\sqrt{LC} \pm RC}{2LC} = \frac{1}{\sqrt{LC}} \pm \frac{R}{2L} \ \rightarrow\ \Delta\omega = \left(\frac{1}{\sqrt{LC}} + \frac{R}{2L}\right) - \left(\frac{1}{\sqrt{LC}} - \frac{R}{2L}\right) = \boxed{\frac{R}{L}}$$

68. (*a*) We write the charge on the capacitor using Eq. 24-1, where the voltage drop across the capacitor is the inductive capacitance multiplied by the circuit current (Eq. 30-25a) and the circuit current is found using the source voltage and circuit impedance (Eqs. 30-27 and 30-28b).

$$Q_0 = CV_{C0} = CI_0 X_C = C\left(\frac{V_0}{Z}\right)X_C = \frac{CV_0}{\omega C\sqrt{R^2 + \left(\omega L - 1/\omega C\right)^2}} = \boxed{\frac{V_0}{\sqrt{\omega^2 R^2 + \left(\omega^2 L - 1/C\right)^2}}}$$

(*b*) We set the derivative of the charge with respect to the frequency equal to zero to calculate the frequency at which the charge is a maximum.

$$\frac{dQ_0}{d\omega} = \frac{d}{d\omega}\frac{V_0}{\sqrt{\omega'^2 R^2 + \left(\omega'^2 L - 1/C\right)^2}} = \frac{-V_0\left(2\omega' R^2 + 4\omega'^3 L^2 - 4\omega' L/C\right)}{\left[\omega'^2 R^2 + \left(\omega'^2 L - 1/C\right)^2\right]^{\frac{3}{2}}} = 0$$

$$\rightarrow \omega' = \boxed{\sqrt{\frac{1}{LC} - \frac{R^2}{2L^2}}}$$

(*c*) The amplitude in a forced damped harmonic oscillation is given by Eq. 14-23. This is equivalent to the *LRC* circuit with $F_0 \leftrightarrow V_0$, $k \leftrightarrow 1/C$, $m \leftrightarrow L$, and $b \leftrightarrow R$.

69. Since the circuit is in resonance, we use Eq. 30-32 for the resonant frequency to determine the necessary inductance. We set this inductance equal to the solenoid inductance calculated in Example 30-3, with the area equal to the area of a circle of radius *r*, the number of turns equal to the length of the wire divided by the circumference of a turn, and the length of the solenoid equal to the diameter of the wire multiplied by the number of turns. We solve the resulting equation for the number of turns.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$f_0 = \frac{1}{2\pi\sqrt{LC}} \quad \rightarrow \quad L = \frac{1}{4\pi^2 f_o^2 C} = \frac{\mu_0 N^2 A}{\ell} = \frac{\mu_0 \left(\frac{\ell_{wire}}{2\pi r}\right)^2 \pi r^2}{Nd} \quad \rightarrow$$

$$N = \frac{\pi f_o^2 C \mu_0 \ell^2_{\ wire}}{d} = \frac{\pi \left(18.0\times10^3\,\text{Hz}\right)^2 \left(2.20\times10^{-7}\,\text{F}\right)\left(4\pi\times10^{-7}\,\text{T•m/A}\right)\left(12.0\,\text{m}\right)^2}{1.1\times10^{-3}\,\text{m}} = \boxed{37\text{ loops}}$$

70. The power on each side of the transformer must be equal. We replace the currents in the power equation with the number of turns in the two coils using Eq. 29-6. Then we solve for the turn ratio.

$$P_p = I_p^2 Z_p = P_s = I_s^2 Z_s \rightarrow \frac{Z_p}{Z_s} = \left(\frac{I_s}{I_p}\right)^2 = \left(\frac{N_p}{N_s}\right)^2$$

$$\rightarrow \frac{N_p}{N_s} = \sqrt{\frac{Z_p}{Z_s}} = \sqrt{\frac{45\times10^3\ \Omega}{8.0\ \Omega}} = \boxed{75}$$

71. (*a*) We calculate the inductance from the resonance frequency.

$$f_0 = \frac{1}{2\pi\sqrt{LC}} \quad \rightarrow$$

$$L = \frac{1}{4\pi^2 f_o^2 C} = \frac{1}{4\pi^2 \left(17\times10^3\,\text{Hz}\right)^2 \left(2.2\times10^{-9}\,\text{F}\right)} = 0.03982\,\text{H} \approx \boxed{0.040\,\text{H}}$$

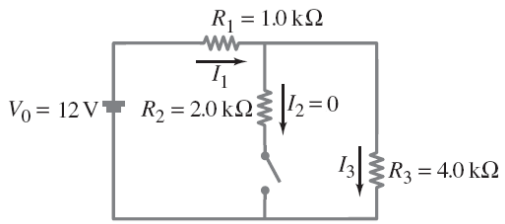
(*b*) We set the initial energy in the electric field, using Eq. 24-5, equal to the maximum energy in the magnetic field, Eq. 30-6, and solve for the maximum current.

$$\tfrac{1}{2}CV_0^2 = \tfrac{1}{2}LI_{\max}^2 \quad \rightarrow \quad I_{\max} = \sqrt{\frac{CV_0^2}{L}} = \sqrt{\frac{\left(2.2\times10^{-9}\,\text{F}\right)\left(120\,\text{V}\right)^2}{\left(0.03984\,\text{H}\right)}} = \boxed{0.028\,\text{A}}$$

(*c*) The maximum energy in the inductor is equal to the initial energy in the capacitor.

$$U_{L,\max} = \tfrac{1}{2}CV_0^2 = \tfrac{1}{2}\left(2.2\times10^{-9}\,\text{F}\right)\left(120\,\text{V}\right)^2 = \boxed{16\,\mu\text{J}}$$

72. We use Eq. 30-6 to calculate the initial energy stored in the inductor.



$$U_0 = \tfrac{1}{2}LI_0^2 = \tfrac{1}{2}\left(0.0600\,\text{H}\right)\left(0.0500\,\text{A}\right)^2 = \boxed{7.50\times10^{-5}\,\text{J}}$$

We set the energy in the inductor equal to five times the initial energy and solve for the current. We set the current equal to the initial current plus the rate of increase multiplied by time and solve for the time.

$$U = \tfrac{1}{2}LI^2 \quad \rightarrow \quad I = \sqrt{\frac{2U}{L}} = \sqrt{\frac{2\left(5.0\times7.50\times10^{-5}\,\text{J}\right)}{0.0600\,\text{H}}} = 111.8\,\text{mA}$$

$$I = I_0 + \beta t \quad \rightarrow \quad t = \frac{I - I_0}{\beta} = \frac{111.8\,\text{mA} - 50.0\,\text{mA}}{78.0\,\text{mA/s}} = \boxed{0.79\,\text{s}}$$

73. When the currents have acquired their steady-state values, the capacitor will be fully charged, and so no current will flow through the capacitor. At this time, the voltage drop across the inductor will be zero, as the current flowing through the inductor is constant. Therefore, the current through R_1 is zero, and the resistors R_2 and R_3 can be treated as in series.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_1 = I_3 = \frac{V_0}{R_1 + R_3} = \frac{12\,\text{V}}{5.0\,\text{k}\Omega} = \boxed{2.4\,\text{mA}} \;\; ; \;\; I_2 = \boxed{0}$$

74. (*a*) The self inductance is written in terms of the magnetic flux in the toroid using Eq. 30-4. We set the flux equal to the magnetic field of a toroid, from Example 28-10. The field is dependent upon the radius of the solenoid, but if the diameter of the solenoid loops is small compared with the radius of the solenoid, it can be treated as approximately constant.

$$L = \frac{N\Phi_B}{I} = \frac{N\left(\pi d^2/4\right)\left(\mu_0 NI/2\pi r_0\right)}{I} = \boxed{\frac{\mu_0 N^2 d^2}{8r_0}}$$

This is consistent with the inductance of a solenoid for which the length is $\ell = 2\pi r_0$.

(*b*) We calculate the value of the inductance from the given data, with r_0 equal to half of the diameter.

$$L = \frac{\mu_0 N^2 d^2}{8r_0} = \frac{\left(4\pi\times10^{-7}\ \text{T•m/A}\right)(550)^2\left(0.020\ \text{m}\right)^2}{8\left(0.33\ \text{m}\right)} = \boxed{58\ \mu\text{H}}$$

75. We use Eq. 30-4 to calculate the self inductance between the two wires. We calculate the flux by integrating the magnetic field from the two wires, using Eq. 28-1, over the region between the two wires. Dividing the inductance by the length of the wire gives the inductance per unit length.

$$L = \frac{\Phi_B}{I} = \frac{1}{I}\int_r^{\ell-r}\left[\frac{\mu_0 I}{2\pi r'} + \frac{\mu_0 I}{2\pi\left(\ell - r'\right)}\right]h dr' = \frac{\mu_0 h}{2\pi}\int_r^{\ell-r}\left[\frac{1}{r'} + \frac{1}{\left(\ell - r'\right)}\right]dr'$$

$$\frac{L}{h} = \frac{\mu_0}{2\pi}\left[\ln\left(r'\right) - \ln\left(\ell - r'\right)\right]_r^{\ell-r} = \frac{\mu_0}{2\pi}\left[\ln\left(\frac{\ell - r}{r}\right) - \ln\left(\frac{r}{\ell - r}\right)\right] = \boxed{\frac{\mu_0}{\pi}\ln\left(\frac{\ell - r}{r}\right)}$$

76. The magnetic energy is the energy density (Eq. 30-7) multiplied by the volume of the spherical shell enveloping the earth.

$$U = u_B V = \frac{B^2}{2\mu_0}\left(4\pi r^2 h\right) = \frac{\left(0.50\times10^{-4}\text{T}\right)^2}{2\left(4\pi\times10^{-7}\ \text{T•m/A}\right)}\left[4\pi\left(6.38\times10^6\text{m}\right)^2\left(5.0\times10^3\text{m}\right)\right] = \boxed{2.5\times10^{15}\text{J}}$$

77. (*a*) For underdamped oscillation, the charge on the capacitor is given by Eq. 30-19, with $\phi = 0$. Differentiating the current with respect to time gives the current in the circuit.

$$Q(t) = Q_0 e^{-\frac{R}{2L}t}\cos\omega' t \;\; ; \;\; I(t) = \frac{dQ}{dt} = -Q_0 e^{-\frac{R}{2L}t}\left(\frac{R}{2L}\cos\omega' t + \omega'\sin\omega' t\right)$$

The total energy is the sum of the energies stored in the capacitor (Eq. 24-5) and the energy stored in the inductor (Eq. 30-6). Since the oscillation is underdamped ($\omega' \gg R/2L$), the cosine term in the current is much smaller than the sine term and can be ignored. The frequency of oscillation is approximately equal to the undamped frequency of Eq. 30-14.

$$U = U_C + U_L = \frac{Q^2}{2C} + \frac{LI^2}{2} = \frac{\left(Q_0 e^{-\frac{R}{2L}t}\cos\omega' t\right)^2}{2C} + \frac{L\left(Q_0 e^{-\frac{R}{2L}t}\right)^2\left(\omega'\sin\omega' t\right)^2}{2}$$

$$= \frac{Q_0^2 e^{-\frac{R}{L}t}}{2C}\left(\cos^2\omega' t + \omega'^2 LC\sin^2\omega' t\right) \approx \boxed{\frac{Q_0^2 e^{-\frac{R}{L}t}}{2C}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We differentiate the energy with respect to time to show the average power dissipation. We then set the power loss per cycle equal to the resistance multiplied by the square of the current. For a lightly damped oscillation, the exponential term does not change much in one cycle, while the sine squared term averages to ½ .

$$\frac{dU}{dt}=\frac{d}{dt}\left(\frac{Q_0^2e^{-\frac{R}{L}t}}{2C}\right)=-\frac{RQ_0^2e^{-\frac{R}{L}t}}{2LC}$$

$$P=-I^2R=-Q_0^2e^{-\frac{R}{L}t}\left(\omega'^2\sin^2\omega' t\right)\approx -Q_0^2e^{-\frac{R}{L}t}\left(\frac{1}{LC}\right)\left(\frac{1}{2}\right)=\boxed{-\frac{RQ_0^2e^{-\frac{R}{L}t}}{2LC}}$$

The change in power in the circuit is equal to the power dissipated by the resistor.

78. Putting an inductor in series with the device will protect it from sudden surges in current. The growth of current in an *LR* circuit is given is Eq. 30-9.

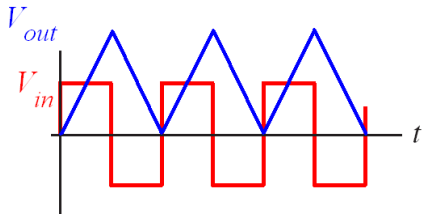
$$I=\frac{V}{R}\left(1-e^{-tR/L}\right)=I_{\max}\left(1-e^{-tR/L}\right)$$

The maximum current is 33 mA, and the current is to have a value of 7.5 mA after a time of 75 microseconds. Use this data to solve for the inductance.

$$I=I_{\max}\left(1-e^{-tR/L}\right)\ \rightarrow\ e^{-tR/L}=1-\frac{I}{I_{\max}}\ \rightarrow$$

$$L=-\frac{tR}{\ln\left(1-\frac{I}{I_{\max}}\right)}=-\frac{\left(75\times10^{-6}\,\text{sec}\right)\left(150\,\Omega\right)}{\ln\left(1-\frac{7.5\,\text{mA}}{33\,\text{mA}}\right)}=4.4\times10^{-2}\,\text{H}$$

Put an inductor of value $4.4\times10^{-2}\,\text{H}$ in series with the device.



79. We use Kirchhoff's loop rule to equate the input voltage to the voltage drops across the inductor and resistor. We then multiply both sides of the equation by the integrating factor $e^{\frac{Rt}{L}}$ and integrate the right-hand side of the equation using a *u* substitution with $u=IRe^{\frac{Rt}{L}}$ and $du=dIRe^{\frac{Rt}{L}}+Ie^{\frac{Rt}{L}}dt/L$

$$V_{in}=L\frac{dI}{dt}+IR\ \rightarrow$$

$$\int V_{in}e^{\frac{Rt}{L}}dt=\int\left(L\frac{dI}{dt}+IR\right)e^{\frac{Rt}{L}}dt=\frac{L}{R}\int du=IR\frac{L}{R}e^{\frac{Rt}{L}}=V_{out}\frac{L}{R}e^{\frac{Rt}{L}}$$

For $L/R<<t$, $e^{\frac{Rt}{L}}\approx1$. Setting the exponential term equal to unity on both sides of the equation gives the desired results.

$$\int V_{in}dt=V_{out}\frac{L}{R}$$

80. (*a*) Since the capacitor and resistor are in series, the impedance of the circuit is given by Eq. 30-28a. Divide the source voltage by the impedance to determine the current in the circuit. Finally, multiply the current by the resistance to determine the voltage drop across the resistor.

$$V_R=IR=\frac{V_{in}}{Z}R=\frac{V_{in}R}{\sqrt{R^2+1/\left(2\pi fC\right)^2}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \frac{(130\text{ mV})(550\ \Omega)}{\sqrt{(550\ \Omega)^2 + 1/\left[2\pi(60\text{ Hz})(1.2\times10^{-6}\text{ F})\right]^2}} = \boxed{31\text{ mV}}$$

(*b*) Repeat the calculation with a frequency of 6.0 kHz.

$$V_R = \frac{(130\text{ mV})(550\ \Omega)}{\sqrt{(550\ \Omega)^2 + 1/\left[2\pi(6000\text{ Hz})(1.2\times10^{-6}\text{ F})\right]^2}} = \boxed{130\text{ mV}}$$

Thus the capacitor allows the higher frequency to pass, but attenuates the lower frequency.

81. (*a*) We integrate the power directly from the current and voltage over one cycle.

$$\bar{P} = \frac{1}{T}\int_0^T IV dt = \frac{\omega}{2\pi}\int_0^{\frac{2\pi}{\omega}} I_0 \sin(\omega t) V_0 \sin(\omega t + 90°)\, dt = \frac{\omega}{2\pi}\int_0^{\frac{2\pi}{\omega}} I_0 \sin(\omega t) V_0 \cos(\omega t)\, dt$$

$$= \frac{\omega}{2\pi} I_0 V_0 \frac{\sin^2(\omega t)}{2\omega}\bigg|_0^{\frac{2\pi}{\omega}} = \frac{I_0 V_0}{4\pi}\left[\sin^2\left(\cancel{\omega}\frac{2\pi}{\cancel{\omega}}\right) - \sin^2(0)\right] = \boxed{0}$$

(*b*) We apply Eq. 30-30, with $\phi = 90°$.

$$\bar{P} = I_{\text{rms}} V_{\text{rms}} \cos 90° = \boxed{0}$$

As expected the average power is the same for both methods of calculation.

82. Since the current lags the voltage one of the circuit elements must be an inductor. Since the angle is less than 90º, the other element must be a resistor. We use 30-29a to write the resistance in terms of the impedance. Then using Eq. 30-27 to determine the impedance from the voltage and current and Eq. 30-28b, we solve for the unknown inductance and resistance.

$$\tan\phi = \frac{2\pi fL}{R} \rightarrow R = 2\pi fL\cot\phi$$

$$Z = \frac{V_{\text{rms}}}{I_{\text{rms}}} = \sqrt{R^2 + (2\pi fL)^2} = \sqrt{(2\pi fL\cot\phi)^2 + (2\pi fL)^2} = 2\pi fL\sqrt{1+\cot^2\phi}$$

$$L = \frac{V_{\text{rms}}}{2\pi f\, I_{\text{rms}}\sqrt{1+\cot^2\phi}} = \frac{120\text{ V}}{2\pi(60\text{ Hz})(5.6\text{ A})\sqrt{1+\cot^2 65°}} = 51.5\text{ mH} \approx \boxed{52\text{ mH}}$$

$$R = 2\pi f\, L\cot\phi = 2\pi(60\text{ Hz})(51.5\text{ mH})\cot 65° = \boxed{9.1\Omega}$$

83. We use Eq. 30-28b to calculate the impedance at 60 Hz. Then we double that result and solve for the required frequency.

$$Z_0 = \sqrt{R^2 + (2\pi f_0 L)^2} = \sqrt{(3500\Omega)^2 + \left[2\pi(60\text{ Hz})(0.44\text{ H})\right]^2} = 3504\Omega$$

$$2Z_0 = \sqrt{R^2 + (2\pi fL)^2} \rightarrow f = \frac{\sqrt{4Z_0^2 - R^2}}{2\pi L} = \frac{\sqrt{4(3504\Omega)^2 - (3500\Omega)^2}}{2\pi(0.44\text{ H})} = \boxed{2.2\text{ kHz}}$$

84. (*a*) We calculate capacitive reactance using Eq. 30-25b. Then using the resistance and capacitive reactance we calculate the impedance. Finally, we use Eq. 30-27 to calculate the rms current.

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(60.0\text{ Hz})(1.80\times10^{-6}\text{ F})} = 1474\Omega$$

$$Z = \sqrt{R^2 + X_C^2} = \sqrt{(5700\Omega)^2 + (1474\Omega)^2} = 5887\Omega$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_{\text{rms}} = \frac{V_{\text{rms}}}{Z} = \frac{120\,\text{V}}{5887\,\Omega} = 20.38\,\text{mA} \approx \boxed{20.4\,\text{mA}}$$

(*b*) We calculate the phase angle using Eq. 30-29a.

$$\phi = \tan^{-1}\frac{-X_C}{R} = \tan^{-1}\frac{-1474\,\Omega}{5700\,\Omega} = \boxed{-14.5°}$$

(*c*) The average power is calculated using Eq. 30-30.

$$\bar{P} = I_{\text{rms}}V_{\text{rms}}\cos\phi = (0.0204\,\text{A})(120\,\text{V})\cos(-14.5°) = \boxed{2.37\,\text{W}}$$

(*d*) The voltmeter will read the rms voltage across each element. We calculate the rms voltage by multiplying the rms current through the element by the resistance or capacitive reactance.

$$V_R = I_{\text{rms}}R = (20.38\,\text{mA})(5.70\,\text{k}\Omega) = \boxed{116\,\text{V}}$$

$$V_C = I_{\text{rms}}X_C = (20.38\,\text{mA})(1474\,\Omega) = \boxed{30.0\,\text{V}}$$

Note that since the voltages are out of phase they do not sum to the applied voltage. However, since they are 90º out of phase their squares sum to the square of the input voltage.

85. We find the resistance using Ohm's law with the dc voltage and current. When then calculate the impedance from the ac voltage and current, and using Eq. 30-28b.

$$R = \frac{V}{I} = \frac{45\,\text{V}}{2.5\,\text{A}} = \boxed{18\,\Omega} \;;\; Z = \frac{V_{\text{rms}}}{I_{\text{rms}}} = \frac{120\,\text{V}}{3.8\,\text{A}} = 31.58\,\Omega$$

$$\sqrt{R^2 + (2\pi fL)^2} \rightarrow L = \frac{\sqrt{Z^2 - R^2}}{2\pi f} = \frac{\sqrt{(31.58\,\Omega)^2 - (18\,\Omega)^2}}{2\pi(60\,\text{Hz})} = \boxed{69\,\text{mH}}$$

86. (*a*) From the text of the problem, the *Q* factor is the ratio of the voltage across the capacitor or inductor to the voltage across the resistor, at resonance. The resonant frequency is given by Eq. 30-32.

$$Q = \frac{V_L}{V_R} = \frac{I_{\text{res}}X_L}{I_{\text{res}}R} = \frac{2\pi f_0 L}{R} = \frac{2\pi\dfrac{1}{2\pi}\sqrt{\dfrac{1}{LC}}L}{R} = \boxed{\frac{1}{R}\sqrt{\frac{L}{C}}}$$

(*b*) Find the inductance from the resonant frequency, and the resistance from the *Q* factor.

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{1}{LC}} \;\rightarrow$$

$$L = \frac{1}{4\pi^2 C f_0^2} = \frac{1}{4\pi^2(1.0\times10^{-8}\,\text{F})(1.0\times10^{6}\,\text{Hz})^2} = 2.533\times10^{-6}\,\text{H} \approx \boxed{2.5\times10^{-6}\,\text{H}}$$

$$Q = \frac{1}{R}\sqrt{\frac{L}{C}} \;\rightarrow\; R = \frac{1}{Q}\sqrt{\frac{L}{C}} = \frac{1}{350}\sqrt{\frac{2.533\times10^{-6}\,\text{H}}{1.0\times10^{-8}\,\text{F}}} = \boxed{4.5\times10^{-2}\,\Omega}$$

87. We calculate the period of oscillation as 2π divided by the angular frequency. Then set the total energy of the system at the beginning of each cycle equal to the charge on the capacitor as given by Eq. 24-5, with the charge given by Eq. 30-19, with $\cos(\omega' t + \phi) = \cos[\omega'(t+T) + \phi] = 1$. We take the difference in energies at the beginning and end of a cycle, divided by the initial energy. For small damping, the argument of the resulting exponential term is small and we replace it with the first two terms of the Taylor series expansion.

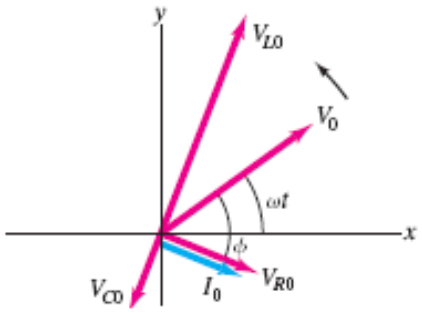
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$T = \frac{2\pi}{\omega'} \approx \frac{2\pi}{\omega} \qquad U_{\max} = \frac{Q_0^2 e^{-\frac{R}{L}t}\cos^2(\omega' t + \phi)}{2C} = \frac{Q_0^2 e^{-\frac{R}{L}t}}{2C}$$

$$\frac{\Delta U}{U} = \frac{Q_0^2 e^{-\frac{R}{L}t} - Q_0^2 e^{-\frac{R}{L}\left(t+\frac{2\pi}{\omega}\right)}}{Q_0^2 e^{-\frac{R}{L}t}} = 1 - e^{-\frac{2\pi R}{\omega L}} \approx 1 - \left(1 - \frac{2\pi R}{\omega L}\right) = \frac{2\pi R}{\omega L} = \boxed{\frac{2\pi}{Q}}$$

88. We set the power factor equal to the resistance divided by the impedance (Eq. 30-28a) with the impedance written in terms of the angular frequency (Eq. 30-28b). We rearrange the resulting equation to form a quadratic equation in terms of the angular frequency. We divide the positive angular frequencies by 2π to determine the desired frequencies.

$$\cos\phi = \frac{R}{Z} = \frac{R}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}} \quad \rightarrow \quad \omega^2 LC \pm \omega C\sqrt{R^2\left(\frac{1}{\cos^2\phi} - 1\right)} - 1 = 0$$



$$\omega^2 (0.033\,\text{H})\left(55\times10^{-9}\,\text{F}\right) \pm \omega\left(55\times10^{-9}\,\text{F}\right)\sqrt{(1500\,\Omega)^2\left(\frac{1}{0.17^2} - 1\right)} - 1 = 0$$

$$\left(1.815\times10^{-9}\,\text{F•H}\right)\omega^2 \pm \left(4.782\times10^{-4}\,\Omega\text{•F}\right)\omega - 1 = 0$$

$$\omega = \frac{\pm 4.78225\times10^{-4}\,\Omega\text{•F} \pm 4.85756\times10^{-4}\,\Omega\text{•F}}{3.63\times10^{-9}\,\text{F•H}} = \pm 2.65\times10^5\,\text{rad/s},\ \pm 2.07\times10^3\,\text{rad/s}$$

$$f = \frac{\omega}{2\pi} = \frac{2.65\times10^5\,\text{rad/s}}{2\pi} = \boxed{42\,\text{kHz}} \quad \text{and} \quad \frac{2.07\times10^3\,\text{rad/s}}{2\pi} = \boxed{330\,\text{Hz}}$$

89. (*a*) We set $V = V_0 \sin\omega t$ and assume the inductive reactance is greater than the capacitive reactance. The current will lag the voltage by an angle ϕ. The voltage across the resistor is in phase with the current and the voltage across the inductor is 90º ahead of the current. The voltage across the capacitor is smaller than the voltage in the inductor, and antiparallel to it.

(*b*) From the diagram, the current is the projection of the maximum current onto the *y* axis, with the current lagging the voltage by the angle ϕ. This is the same angle obtained in Eq. 30-29a. The magnitude of the maximum current is the voltage divided by the impedance, Eq. 30-28b.

$$I(t) = I_0 \sin(\omega t - \phi) = \boxed{\frac{V_0}{\sqrt{R^2 + (\omega L - 1/\omega C)^2}}\sin(\omega t - \phi)} \ ; \ \phi = \tan^{-1}\frac{\omega L - 1/\omega C}{R}$$

90. (*a*) We use Eq. 30-28b to calculate the impedance and Eq. 30-29a to calculate the phase angle.

$$X_L = \omega L = (754\,\text{rad/s})(0.0220\,\text{H}) = 16.59\,\Omega$$

$$X_C = 1/\omega C = 1/(754\,\text{rad/s})\left(0.42\times10^{-6}\,\text{F}\right) = 3158\,\Omega$$

$$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{\left(23.2\times10^3\,\Omega\right)^2 + \left[16.59\,\Omega - 3158\,\Omega\right]^2} = \boxed{23.4\,\text{k}\Omega}$$

$$\phi = \tan^{-1}\frac{X_L - X_C}{R} = \tan^{-1}\frac{16.59\,\Omega - 3158\,\Omega}{23.2\times10^3\,\Omega} = \boxed{-7.71°}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We use Eq. 30-30 to obtain the average power. We obtain the rms voltage by dividing the maximum voltage by $\sqrt{2}$. The rms current is the rms voltage divided by the impedance.

$$\bar{P} = I_{\text{rms}} V_{\text{rms}} \cos\phi = \frac{V_{\text{rms}}^2}{Z}\cos\phi = \frac{V_0^2}{2Z}\cos\phi = \frac{(0.95\,\text{V})^2}{2\left(23.4\times10^3\,\Omega\right)}\cos(-7.71°) = \boxed{19\,\mu\text{W}}$$

(*c*) The rms current is the peak voltage, divided by $\sqrt{2}$, and then divided by the impedance.

$$I_{\text{rms}} = \frac{V_0/\sqrt{2}}{Z} = \frac{0.95\,\text{V}/\sqrt{2}}{23.4\times10^3\,\Omega} = 2.871\times10^{-5}\,\text{A} \approx \boxed{29\,\mu\text{A}}$$

The rms voltage across each element is the rms current times the resistance or reactance of the element.

$$V_R = I_{\text{rms}} R = \left(2.871\times10^{-5}\,\text{A}\right)\left(23.2\times10^3\,\Omega\right) = \boxed{0.67\,\text{V}}$$

$$V_C = I_{\text{rms}} X_C = \left(2.871\times10^{-5}\,\text{A}\right)(3158\,\Omega) = \boxed{0.091\,\text{V}}$$

$$V_L = I_{\text{rms}} X_L = \left(2.871\times10^{-5}\,\text{A}\right)(16.59\,\Omega) = \boxed{4.8\times10^{-4}\,\text{V}}$$

91. (*a*) The impedance of the circuit is given by Eq. 30-28b with $X_L > X_C$ and $R = 0$. We divide the magnitude of the ac voltage by the impedance to get the magnitude of the ac current in the circuit. Since $X_L > X_C$, the voltage will lead the current by $\phi = \pi/2$. No dc current will flow through the capacitor.

$$Z = \sqrt{R^2 + (\omega L - 1/\omega C)^2} = \omega L - 1/\omega C \qquad I_0 = \frac{V_{20}}{Z} = \frac{V_{20}}{\omega L - 1/\omega C}$$

$$I(t) = \boxed{\frac{V_{20}}{\omega L - 1/\omega C}\sin(\omega t - \pi/2)}$$

(*b*) The voltage across the capacitor at any instant is equal to the charge on the capacitor divided by the capacitance. This voltage is the sum of the ac voltage and dc voltage. There is no dc voltage drop across the inductor so the dc voltage drop across the capacitor is equal to the input dc voltage.

$$V_{\text{out,ac}} = V_{\text{out}} - V_1 = \frac{Q}{C} - V_1$$

We treat the emf as a superposition of the ac and dc components. At any instant of time the sum of the voltage across the inductor and capacitor will equal the input voltage. We use Eq. 30-5 to calculate the voltage drop across the inductor. Subtracting the voltage drop across the inductor from the input voltage gives the output voltage. Finally, we subtract off the dc voltage to obtain the ac output voltage.

$$V_L = L\frac{dI}{dt} = L\frac{d}{dt}\left[\frac{V_{20}}{\omega L - 1/\omega C}\sin(\omega t - \pi/2)\right] = \frac{V_{20}L\omega}{\omega L - 1/\omega C}\cos(\omega t - \pi/2)$$

$$= \frac{V_{20}L\omega}{\omega L - 1/\omega C}\sin(\omega t)$$

$$V_{\text{out}} = V_{\text{in}} - V_L = V_1 + V_{20}\sin\omega t - \left(\frac{V_{20}L\omega}{\omega L - 1/\omega C}\sin(\omega t)\right)$$

$$= V_1 + V_{20}\left(1 - \frac{L\omega}{\omega L - 1/\omega C}\right)\sin(\omega t) = V_1 - V_{20}\left(\frac{1/\omega C}{\omega L - 1/\omega C}\right)\sin(\omega t)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$V_{\text{out,ac}} = V_{\text{out}} - V_1 = -V_{20}\left(\frac{1/\omega C}{\omega L - 1/\omega C}\right)\sin(\omega t) = \boxed{\left(\frac{V_{20}}{\omega^2 LC - 1}\right)\sin(\omega t - \pi)}$$

(*c*) The attenuation of the ac voltage is greatest when the denominator is large.

$$\omega^2 LC \gg 1 \rightarrow \omega L \gg \frac{1}{\omega C} \rightarrow X_L \gg X_C$$

We divide the output ac voltage by the input ac voltage to obtain the attenuation.

$$\frac{V_{2,\text{out}}}{V_{2,\text{in}}} = \frac{\dfrac{V_{20}}{\omega^2 LC - 1}}{V_{20}} = \frac{1}{\omega^2 LC - 1} \approx \boxed{\frac{1}{\omega^2 LC}}$$

(*d*) The dc output is equal to the dc input, since there is no dc voltage drop across the inductor.

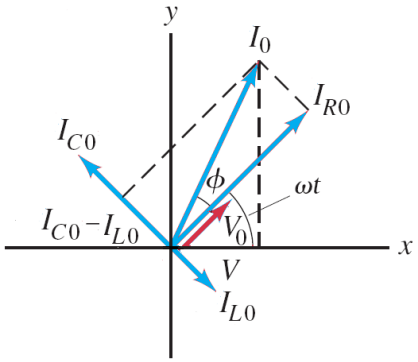
$$\boxed{V_{1,\text{out}} = V_1}$$

92. Since no dc current flows through the capacitor, there will be no dc current through the resistor. Therefore the dc voltage passes through the circuit with little attenuation. The ac current in the circuit is found by dividing the input ac voltage by the impedance (Eq. 30-28b) We obtain the output ac voltage by multiplying the ac current by the capacitive reactance. Dividing the result by the input ac voltage gives the attenuation.

$$V_{2,\text{out}} = IX_C = \frac{V_{20}X_C}{\sqrt{R^2 + X_C^2}} \quad \rightarrow \quad \frac{V_{2,\text{out}}}{V_{20}} = \frac{1}{\sqrt{R^2\omega^2C^2 + 1}} \approx \boxed{\frac{1}{R\omega C}}$$

93. (*a*) Since the three elements are connected in parallel, at any given instant in time they will all three have the same voltage drop across them. That is the voltages across each element will be in phase with the source. The current in the resistor is in phase with the voltage source with magnitude given by Ohm's law.

$$I_R(t) = \boxed{\frac{V_0}{R}\sin\omega t}$$



(*b*) The current through the inductor will lag behind the voltage by π/2, with magnitude equal to the voltage source divided by the inductive reactance.

$$I_L(t) = \boxed{\frac{V_0}{X_L}\sin\left(\omega t - \frac{\pi}{2}\right)}$$

(*c*) The current through the capacitor leads the voltage by π/2, with magnitude equal to the voltage source divided by the capacitive reactance.

$$I_C(t) = \boxed{\frac{V_0}{X_C}\sin\left(\omega t + \frac{\pi}{2}\right)}$$

(*d*) The total current is the sum of the currents through each element. We use a phasor diagram to add the currents, as was used in Section 30-8 to add the voltages with different phases. The net current is found by subtracting the current through the inductor from the current through the capacitor. Then using the Pythagorean theorem to add the current through the resistor. We use the tangent function to find the phase angle between the current and voltage source.

$$I_0 = \sqrt{I_{R0}^2 + (I_{C0} - I_{L0})^2} = \sqrt{\left(\frac{V_0}{R}\right)^2 + \left(\frac{V_0}{X_C} - \frac{V_0}{X_L}\right)^2} = \frac{V_0}{R}\sqrt{1 + \left(R\omega C - \frac{1}{R\omega L}\right)^2}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I(t) = \boxed{\frac{V_0}{R}\sqrt{1+\left(R\omega C - \frac{R}{\omega L}\right)^2}\sin\left(\omega t + \phi\right)}$$

$$\tan\phi = \frac{\frac{V_0}{X_C} - \frac{V_0}{X_L}}{\frac{V_0}{R}} \rightarrow \phi = \tan^{-1}\left(\frac{R}{X_C} - \frac{R}{X_L}\right) = \boxed{\tan^{-1}\left(R\omega C - \frac{R}{\omega L}\right)}$$

(*e*) We divide the magnitude of the voltage source by the magnitude of the current to find the impedance.

$$Z = \frac{V_0}{I_0} = \frac{V_0}{\frac{V_0}{R}\sqrt{1+\left(R\omega C - \frac{R}{\omega L}\right)^2}} = \boxed{\frac{R}{\sqrt{1+\left(R\omega C - \frac{R}{\omega L}\right)^2}}}$$

(*f*) The power factor is the ratio of the power dissipated in the circuit divided by the product of the rms voltage and current.

$$\frac{I_{R,\text{rms}}^2 R}{V_{\text{rms}} I_{\text{rms}}} = \frac{I_R^2 R}{V_0 I_0} = \frac{\left(\frac{V_0}{R}\right)^2 R}{V_0 \frac{V_0}{R}\sqrt{1+\left(R\omega C - \frac{R}{\omega L}\right)^2}} = \boxed{\frac{1}{\sqrt{1+\left(R\omega C - \frac{R}{\omega L}\right)^2}}}$$

94. We find the equivalent values for each type of element in series. From the equivalent values we calculate the impedance using Eq. 30-28b.

$$R_{\text{eq}} = R_1 + R_2 \qquad \frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} \qquad L_{\text{eq}} = L_1 + L_2$$

$$Z = \sqrt{R_{\text{eq}}^2 + \left(\omega L_{\text{eq}} - \frac{1}{\omega C_{\text{eq}}}\right)^2} = \boxed{\sqrt{\left(R_1 + R_2\right)^2 + \left(\omega L_1 + \omega L_2 - \frac{1}{\omega C_1} - \frac{1}{\omega C_2}\right)^2}}$$

95. If there is no current in the secondary, there will be no induced emf from the mutual inductance. Therefore, we set the ratio of the voltage to current equal to the inductive reactance and solve for the inductance.

$$\frac{V_{\text{rms}}}{I_{\text{rms}}} = X_L = 2\pi f L \rightarrow L = \frac{V_{\text{rms}}}{2\pi f\, I_{\text{rms}}} = \frac{220\text{ V}}{2\pi\left(60\text{ Hz}\right)\left(4.3\text{ A}\right)} = \boxed{0.14\text{ H}}$$

96. (*a*) We use Eq. 24-2 to calculate the capacitance, assuming a parallel plate capacitor.

$$C = \frac{K\varepsilon_0 A}{d} = \frac{\left(5.0\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(1.0\times10^{-4}\,\text{m}^2\right)}{2.0\times10^{-3}\,\text{m}} = 2.213\times10^{-12}\,\text{F} \approx \boxed{2.2\,\text{pF}}$$

(*b*) We use Eq. 30-25b to calculate the capacitive reactance.

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi\left(12000\,\text{Hz}\right)\left(2.2\times10^{-12}\,\text{F}\right)} = 5.995\times10^6\,\Omega \approx \boxed{6.0\,\text{M}\Omega}$$

(*c*) Assuming that the resistance in the plasma and in the person is negligible compared with the capacitive reactance, calculate the current by dividing the voltage by the capacitive reactance.

$$I_{\text{o}} \approx \frac{V_{\text{o}}}{X_C} = \frac{2500\text{ V}}{5.995\times10^6\,\Omega} = 4.17\times10^{-4}\,\text{A} \approx \boxed{0.42\,\text{mA}}$$

This is not a dangerous current level.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*d*) We replace the frequency with 1.0 MHz and recalculate the current.

$$I_0 \approx \frac{V_0}{X_C} = 2\pi fCV_0 = 2\pi\left(1.0\times10^6\,\text{Hz}\right)\left(2.2\times10^{-12}\,\text{F}\right)\left(2500\,\text{V}\right) = \boxed{35\,\text{mA}}$$

This current level is dangerous.

97. We calculate the resistance from the power dissipated and the current. Then setting the ratio of the voltage to current equal to the impedance, we solve for the inductance.

$$\bar{P} = I_{\text{rms}}^2 R \rightarrow R = \frac{\bar{P}}{I_{\text{rms}}^2} = \frac{350\,\text{W}}{\left(4.0\,\text{A}\right)^2} = 21.88\,\Omega \approx \boxed{22\,\Omega}$$

$$Z = \frac{V_{\text{rms}}}{I_{\text{rms}}} = \sqrt{R^2 + \left(2\pi fL\right)^2} \quad \rightarrow$$

$$L = \frac{\sqrt{\left(V_{\text{rms}}/I_{\text{rms}}\right)^2 - R^2}}{2\pi f} = \frac{\sqrt{\left(120\,\text{V}/4.0\,\text{A}\right)^2 - \left(21.88\,\Omega\right)^2}}{2\pi\left(60\,\text{Hz}\right)} = \boxed{54\,\text{mH}}$$

98. We insert the proposed current into the differential equation and solve for the unknown peak current and phase.

$$\begin{aligned} V_0 \sin\omega t &= L\frac{d}{dt}\left[I_0 \sin\left(\omega t - \phi\right)\right] + RI_0 \sin\left(\omega t - \phi\right) \\ &= L\omega I_0 \cos\left(\omega t - \phi\right) + RI_0 \sin\left(\omega t - \phi\right) \\ &= L\omega I_0 \left(\cos\omega t\cos\phi + \sin\omega t\sin\phi\right) + RI_0 \left(\sin\omega t\cos\phi - \cos\omega t\sin\phi\right) \\ &= \left(L\omega I_0 \cos\phi - RI_0 \sin\phi\right)\cos\omega t + \left(L\omega I_0 \sin\phi + RI_0 \cos\phi\right)\sin\omega t \end{aligned}$$

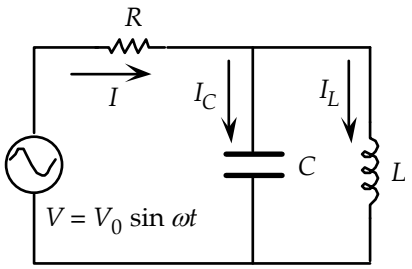
For the given equation to be a solution for all time, the coefficients of the sine and cosine terms must independently be equal.

For the $\cos\omega t$ term:

$$0 = L\omega I_0 \cos\phi - RI_0 \sin\phi \rightarrow \tan\phi = \frac{\omega L}{R} \rightarrow \boxed{\phi = \tan^{-1}\frac{\omega L}{R}}$$

For the $\sin\omega t$ term:

$$V_0 = L\omega I_0 \sin\phi + RI_0 \cos\phi$$



$$I_0 = \frac{V_0}{L\omega\sin\phi + R\cos\phi} = \frac{V_0}{L\omega\dfrac{\omega L}{\sqrt{R^2+\omega^2L^2}} + R\dfrac{R}{\sqrt{R^2+\omega^2L^2}}} = \boxed{\frac{V_0}{\sqrt{R^2+\omega^2L^2}}}$$

99. The peak voltage across either element is the current through the element multiplied by the reactance. We set the voltage across the inductor equal to six times the voltage across the capacitor and solve for the frequency in terms of the resonant frequency, Eq. 30-14.

$$V_L = I_0 2\pi fC = 6V_C = \frac{6I_0}{2\pi fC} \quad \rightarrow \quad \rightarrow \quad f = \frac{1}{2\pi}\sqrt{\frac{6}{LC}} = \boxed{\sqrt{6}\,f_0}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

100. We use Kirchhoff's junction rule to write an equation relating the currents in each branch, and the loop rule to write two equations relating the voltage drops around each loop. We write the voltage drops across the capacitor and inductor in terms of the charge and derivative of the current.

$$I_R = I_L + I_C$$

$$V_0 \sin \omega t - I_R R - \frac{Q_C}{C} = 0 \;\; ; \;\; V_0 \sin \omega t - I_R R - L\frac{dI_L}{dt} = 0$$

We combine these equations to eliminate the charge in the capacitor and the current in the inductor to write a single differential equation in terms of the current through the resistor.

$$\frac{dI_L}{dt} = \frac{V_0}{L}\sin \omega t - \frac{I_R R}{L}$$

$$\frac{dI_C}{dt} = \frac{d^2 Q_C}{dt^2} = \frac{d^2}{dt^2}\left(CV_0 \sin \omega t - I_R RC\right) = -CV_0\omega^2 \sin \omega t - RC\frac{dI_R{}^2}{dt^2}$$

$$\frac{dI_R}{dt} = \frac{dI_L}{dt} + \frac{dI_C}{dt} = -\frac{V_0}{L}\sin \omega t + \frac{I_R R}{L} - CV_0\omega^2 \sin \omega t - RC\frac{dI_R{}^2}{dt^2}$$

We set the current in the resistor, $I_R = I_0 \sin\left(\omega t + \phi\right) = I_0\left(\sin \omega t \cos\phi + \cos \omega t \sin\phi\right)$, equal to the current provided by the voltage source and take the necessary derivatives.

$$I_0 \frac{d}{dt}\left(\sin \omega t \cos\phi + \cos \omega t \sin\phi\right) = \frac{V_0}{L}\sin \omega t - \left(\sin \omega t \cos\phi + \cos \omega t \sin\phi\right)\frac{I_0 R}{L} - CV_0\omega^2 \sin \omega t$$
$$- RCI_0 \frac{d^2}{dt^2}\left(\sin \omega t \cos\phi + \cos \omega t \sin\phi\right)$$

$$I_0\omega \cos \omega t \cos\phi - I_0\omega \sin \omega t \sin\phi = \frac{V_0}{L}\sin \omega t - \frac{I_0 R}{L}\sin \omega t \cos\phi + \frac{I_0 R}{L}\cos \omega t \sin\phi - CV_0\omega^2 \sin \omega t$$
$$+ RCI_0\omega^2 \sin \omega t \cos\phi + RCI_0\omega^2 \cos \omega t \sin\phi$$

Setting the coefficients of the time dependent sine and cosine terms separately equal to zero enables us to solve for the magnitude and phase of the current through the voltage source. We also use Eq. 30-23b and Eq. 30-25b to write the inductance and capacitance in terms of their respective reactances.

From the $\cos(\omega t)$ term:

$$I_0\omega \cos\phi = \frac{I_0\omega R}{X_L}\sin\phi - \frac{I_0 R\omega}{X_C}\sin\phi \rightarrow \tan\phi = \frac{X_L X_C}{R\left(X_L - X_C\right)} \rightarrow \phi = \tan^{-1}\left[\frac{X_L X_C}{R\left(X_L - X_C\right)}\right]$$

From the $\sin(\omega t)$ term:

$$-I_0\omega \sin\phi = \frac{V_0\omega}{X_L} - \frac{I_0\omega R}{X_L}\cos\phi - \frac{V_0\omega}{X_C} + \frac{RI_0\omega}{X_C}\cos\phi$$

$$I_0 = \frac{V_0\left(X_C - X_L\right)}{X_C X_L \sin\phi + R\left(X_C - X_L\right)\cos\phi}$$

$$= \frac{V_0\left(X_C - X_L\right)}{X_C X_L \dfrac{X_C X_L}{\sqrt{\left(X_C X_L\right)^2 + R^2\left(X_C - X_L\right)^2}} + R\left(X_C - X_L\right)\dfrac{R\left(X_C - X_L\right)}{\sqrt{\left(X_C X_L\right)^2 + R^2\left(X_C - X_L\right)^2}}}$$

$$= \frac{V_0\left(X_C - X_L\right)}{\sqrt{\left(X_C X_L\right)^2 + R^2\left(X_C - X_L\right)^2}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

This gives us the current through the power source and resistor. We insert these values back into the junction and loop equations to determine the current in each element as a function of time. We calculate the impedance of the circuit by dividing the peak voltage by the peak current through the voltage source.

$$Z = \frac{V_0}{I_0} = \boxed{\frac{\sqrt{\left(X_C X_L\right)^2 + R^2\left(X_C - X_L\right)^2}}{\left(X_C - X_L\right)}} \;;\; \phi = \boxed{\tan^{-1}\left[\frac{X_L X_C}{R\left(X_L - X_C\right)}\right]} \;;\; I_R = \boxed{\frac{V_0}{Z}\sin\left(\omega t + \phi\right)}$$

$$I_C = \frac{dQ_C}{dt} = \frac{d}{dt}\left(CV_0 \sin\omega t - I_R RC\right) = CV_0\omega\cos\omega t - RC\frac{dI_R}{dt}$$

$$= \boxed{\frac{V_0}{X_C}\left[\cos\omega t - \frac{R}{Z}\cos\left(\omega t + \phi\right)\right]}$$

$$I_L = I_R - I_C = \frac{V_0}{Z}\sin\left(\omega t + \phi\right) - \frac{V_0}{X_C}\left[\cos\omega t - \frac{R}{Z}\cos\left(\omega t + \phi\right)\right]$$

$$= \boxed{\frac{V_0}{Z}\left[\sin\left(\omega t + \phi\right) + \frac{R}{X_C}\cos\left(\omega t + \phi\right)\right] - \frac{V_0}{X_C}\cos\omega t}$$

101. (*a*) The resonant frequency is given by Eq. 30-32. At resonance, the impedance is equal to the resistance, so the rms voltage of the circuit is equal to the rms voltage across the resistor.

$$f = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{\left(0.0050\,\text{H}\right)\left(0.10\times10^{-6}\,\text{F}\right)}} = 7118\,\text{Hz} \approx \boxed{7.1\,\text{kHz}}$$

$$\left(V_R\right)_{\text{rms}} = \boxed{V_{\text{rms}}}$$

(*b*) We set the inductance equal to 90% of the initial inductance and use Eq. 30-28b to calculate the new impedance. Dividing the rms voltage by the impedance gives the rms current. We multiply the rms current by the resistance to determine the voltage drop across the resistor.

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi\left(7118\,\text{Hz}\right)\left(0.10\times10^{-6}\,\text{F}\right)} = 223.6\,\Omega$$

$$X_L = 2\pi fL = 2\pi\left(7118\,\text{Hz}\right)\left(0.90\right)\left(0.0050\,\text{H}\right) = 201.3\,\Omega$$

$$Z = \sqrt{R^2 + \left(X_L - X_C\right)^2} = \sqrt{\left(45\,\Omega\right)^2 + \left(201.3\,\Omega - 223.6\,\Omega\right)^2} = 50.24\,\Omega$$

$$\left(V_R\right)_{\text{rms}} = \left(\frac{R}{Z}\right)V_{\text{rms}} = \left(\frac{45\,\Omega}{50.24\,\Omega}\right)V_{\text{rms}} = \boxed{0.90V_{\text{rms}}}$$

102. With the given applied voltage, calculate the rms current through each branch as the rms voltage divided by the impedance in that branch.

$$I_{C,\text{rms}} = \frac{V_{\text{rms}}}{\sqrt{R_1^2 + X_C^2}} \qquad I_{L,\text{rms}} = \frac{V_{\text{rms}}}{\sqrt{R_2^2 + X_L^2}}$$

Calculate the potential difference between points a and b in two ways. First pass through the capacitor and then through R_2. Then pass through R_1 and the inductor.

$$V_{\text{ab}} = I_C X_C - I_L R_2 = \frac{V_{\text{rms}} X_C}{\sqrt{R_1^2 + X_C^2}} - \frac{V_{\text{rms}} R_2}{\sqrt{R_2^2 + X_L^2}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$V_{ab} = -I_C R_1 + X_L I_L = -\frac{V_{rms} R_1}{\sqrt{R_1^2 + X_C^2}} + \frac{V_{rms} X_L}{\sqrt{R_2^2 + X_L^2}}$$

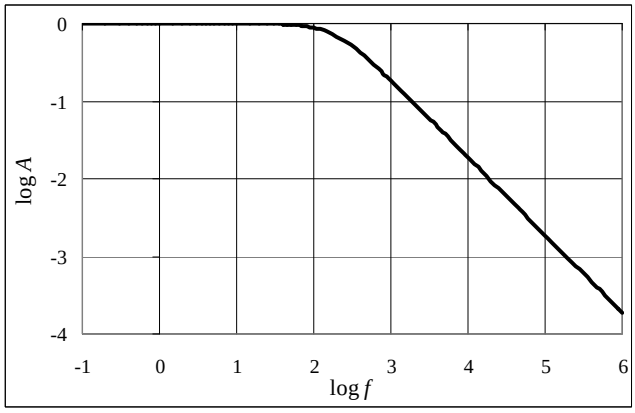
Set these voltage differences equal to zero, and rearrange the equations.

$$\frac{V_{rms} X_C}{\sqrt{R_1^2 + X_C^2}} - \frac{V_{rms} R_2}{\sqrt{R_2^2 + X_L^2}} = 0 \rightarrow X_C \sqrt{R_2^2 + X_L^2} = R_2 \sqrt{R_1^2 + X_C^2}$$

$$-\frac{V_{rms} R_1}{\sqrt{R_1^2 + X_C^2}} + \frac{V_{rms} X_L}{\sqrt{R_2^2 + X_L^2}} = 0 \rightarrow R_1 \sqrt{R_2^2 + X_L^2} = X_L \sqrt{R_1^2 + X_C^2}$$

Divide the resulting equations and solve for the product of the resistances. Write the reactances in terms of the capacitance and inductance to show that the result is frequency independent.

$$\frac{X_C \sqrt{R_2^2 + X_L^2}}{R_1 \sqrt{R_2^2 + X_L^2}} = \frac{R_2 \sqrt{R_1^2 + X_C^2}}{X_L \sqrt{R_1^2 + X_C^2}} \rightarrow R_1 R_2 = X_L X_C = \frac{\omega L}{\omega C} \rightarrow \boxed{R_1 R_2 = \frac{L}{C}}$$



103. (*a*) The output voltage is the voltage across the capacitor, which is the current through the circuit multiplied by the capacitive reactance. We calculate the current by dividing the input voltage by the impedance. Finally, we divide the output voltage by the input voltage to calculate the gain.

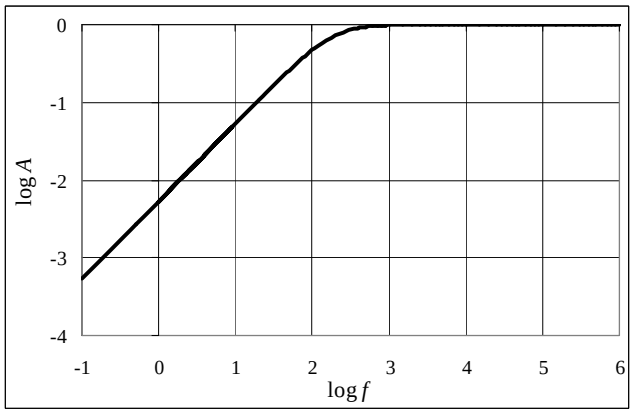
$$V_{out} = IX_C = \frac{V_{in} X_C}{\sqrt{R^2 + X_C^2}} = \frac{V_{in}}{\sqrt{(R/X_C)^2 + 1}} = \frac{V_{in}}{\sqrt{(2\pi fCR)^2 + 1}}$$

$$A = \frac{V_{out}}{V_{in}} = \boxed{\frac{1}{\sqrt{4\pi^2 f^2 C^2 R^2 + 1}}}$$

(*b*) As the frequency goes to zero, the gain becomes one. In this instance the capacitor becomes fully charged, so no current flows across the resistor. Therefore the output voltage is equal to the input voltage. As the frequency becomes very large, the capacitive reactance becomes very small, allowing a large current. In this case, most of the voltage drop is across the resistor, and the gain goes to zero.

(*c*) See the graph of the log of the gain as a function of the log of the frequency. Note that for frequencies less than about 100 Hz the gain is ~ 1. For higher frequencies the gain drops off proportionately to the frequency. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH30.XLS," on tab "Problem 30.103c."

104. (*a*) The output voltage is the voltage across the resistor, which is the current through the circuit multiplied by the resistance. We calculate the current by dividing the input voltage by the impedance. Finally, we divide the output voltage by the input voltage to calculate the gain.

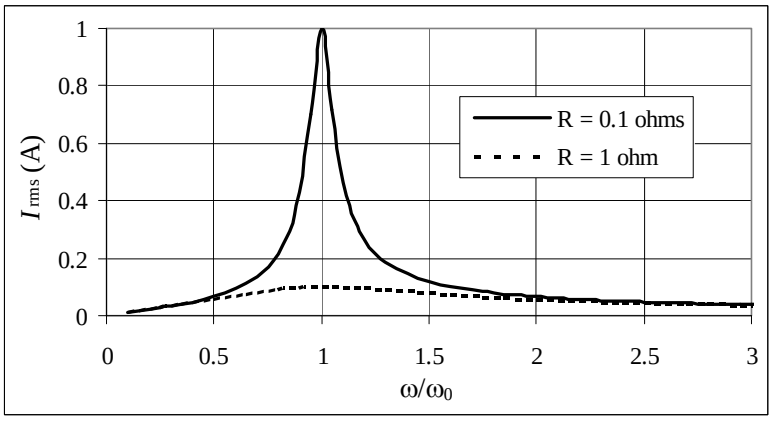


$$V_{out} = IR = \frac{V_{in} R}{\sqrt{R^2 + X_C^2}} = \frac{V_{in} R}{\sqrt{R^2 + \left(\frac{1}{2\pi fC}\right)^2}} = \frac{2\pi fCRV_{in}}{\sqrt{(2\pi fCR)^2 + 1}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$A = \frac{V_{\text{out}}}{V_{\text{in}}} = \boxed{\frac{2\pi fCR}{\sqrt{4\pi^2 f^2 C^2 R^2 + 1}}}$$

(*b*) As the frequency goes to zero, the gain drops to zero. In this instance the capacitor becomes fully charged, so no current flows across the resistor. Therefore the output voltage drops to zero. As the frequency becomes very large, the capacitive reactance becomes very small, allowing a large current. In this case, most of the voltage drop is across the resistor, and the gain is equal to unity.



(*c*) See the graph of the log of the gain as a function of the log of the frequency. Note that for frequencies greater than about 1000 Hz the gain is ~ 1. For lower frequencies the gain drops off proportionately to the inverse of the frequency. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH30.XLS," on tab "Problem 30.104c."

105. We calculate the resonant frequency using Eq. 30-32.

$$\omega_0 = \frac{1}{\sqrt{LC}} = \frac{1}{\sqrt{\left(50\times10^{-6}\,\text{H}\right)\left(50\times10^{-6}\,\text{F}\right)}} = 20{,}000\,\text{rad/s}$$

Using a spreadsheet, we calculate the impedance as a function of frequency using Eq. 30-28b. We divide the rms voltage by the impedance to plot the rms current as a function of frequency. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH30.XLS," on tab "Problem 30.105."

CHAPTER 31: Maxwell's Equations and Electromagnetic Waves

Responses to Questions

1. The magnetic field will be clockwise in both cases. In the first case, the electric field is away from you and is increasing. The direction of the displacement current (proportional to $\frac{d\Phi_E}{dt}$) is therefore away from you and the corresponding magnetic field is clockwise. In the second case, the electric field is directed towards you and is decreasing; the displacement current is still away from you, and the magnetic field is still clockwise.

2. The displacement current is to the right.

3. The displacement current is spread out over a larger area than the conduction current. Thus, the displacement current produces a less intense field at any given point.

4. One possible reason the term $\varepsilon_0 \frac{d\Phi_E}{dt}$ can be called a "current" is because it has units of amperes.

5. The magnetic field vector will oscillate up and down, perpendicular to the direction of propagation and to the electric field vector.

6. No. Sound is a longitudinal mechanical wave. It requires the presence of a medium; electromagnetic waves do not require a medium.

7. EM waves are self-propagating and can travel through a perfect vacuum. Sound waves are mechanical waves which require a medium, and therefore cannot travel through a perfect vacuum.

8. No. Electromagnetic waves travel at a very large but finite speed. When you flip on a light switch, it takes a very small amount of time for the electrical signal to travel along the wires.

9. The wavelengths of radio and television signals are longer than those of visible light.

10. The wavelength of the current is 5000 km; the house is only 200 km away. The phase of the current at the position of the house is $2\pi/25$ radians different from the phase at the source due to the position of the house.

11. The signals travel through the wires at close to the speed of light, so the length of the wires in a normal room will have an insignificant effect.

12. 10^3 km: radio wave; 1 km: radio wave; 1 m: microwave; 1 cm: microwave; 1 mm: microwave or infrared; 1 μm: infrared.

13. Yes, although the wavelengths for radio waves will be much longer than for sound waves, since the radio waves travel at the speed of light.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

14. Both cordless phones and cellular phones are radio receivers and transmitters. When you speak, the phone converts the sound waves into electrical signals which are amplified, modulated, and transmitted. The receiver picks up the EM waves and converts them back into sound. Cordless phones and cell phones use different frequency ranges and different intensities.

15. Yes. If one signal is sent by amplitude modulation and the other signal is sent by frequency modulation, both could be carried over the same carrier frequency. There are other ways two signals can be sent on the same carrier frequency which are more complex.

16. The receiver's antenna should also be vertical for the best reception.

17. Diffraction is significant when the order of magnitude of the wavelength of the waves is the same as the size of the obstacles. AM waves have longer wavelengths than FM waves and will be more likely to diffract around hills and other landscape barriers.

18. It is amplitude modulated, or AM. The person flashing the light on and off is changing the amplitude of the light ("on" is maximum amplitude and "off" is zero). The frequency of the carrier wave is just the frequency of the visible light, approximately 10^{14} to 10^{15} Hz.

Solutions to Problems

1. The electric field between the plates is given by $E = \dfrac{V}{d}$, where *d* is the distance between the plates.

$$E = \frac{V}{d} \quad \rightarrow \quad \frac{dE}{dt} = \frac{1}{d}\frac{dV}{dt} = \left(\frac{1}{0.0011\,\text{m}}\right)\left(120\,\text{V/s}\right) = \boxed{1.1\times10^{5}\,\frac{\text{V/m}}{\text{s}}}$$

2. The displacement current is shown in section 31-1 to be $I_{\text{D}} = \varepsilon_0 A\dfrac{dE}{dt}$.

$$I_{\text{D}} = \varepsilon_0 A\frac{dE}{dt} = \left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(0.058\,\text{m}\right)^2\left(2.0\times10^{6}\,\frac{\text{V}}{\text{m•s}}\right) = \boxed{6.0\times10^{-8}\,\text{A}}$$

3. The current in the wires must also be the displacement current in the capacitor. Use the displacement current to find the rate at which the electric field is changing.

$$I_D = \varepsilon_0 A\frac{dE}{dt} \quad \rightarrow \quad \frac{dE}{dt} = \frac{I_{\text{D}}}{\varepsilon_0 A} = \frac{\left(2.8\,\text{A}\right)}{\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(0.0160\,\text{m}\right)^2} = \boxed{1.2\times10^{15}\,\frac{\text{V}}{\text{m•s}}}$$

4. The current in the wires is the rate at which charge is accumulating on the plates and also is the displacement current in the capacitor. Because the location in question is outside the capacitor, use the expression for the magnetic field of a long wire.

$$B = \frac{\mu_0 I}{2\pi R} = \left(\frac{\mu_0}{4\pi}\right)\frac{2I}{R} = \frac{\left(10^{-7}\,\text{T•m/A}\right)2\left(38.0\times10^{-3}\,\text{A}\right)}{\left(0.100\,\text{m}\right)} = \boxed{7.60\times10^{-8}\,\text{T}}$$

After the capacitor is fully charged, all currents will be zero, so the magnetic field will be zero.

5. The electric field between the plates is given by $E = \dfrac{V}{d}$, where *d* is the distance between the plates.

The displacement current is shown in section 31-1 to be $I_{\text{D}} = \varepsilon_0 A \dfrac{dE}{dt}$.

$$I_{\text{D}} = \varepsilon_0 A \frac{dE}{dt} = \varepsilon_0 A \frac{1}{d}\frac{dV}{dt} = \frac{\varepsilon_0 A}{d}\frac{dV}{dt} = \boxed{C\frac{dV}{dt}}$$

6. (*a*) The footnote on page 816 indicates that Kirchhoff's junction rule is valid at a capacitor plate, and so the conduction current is the same value as the displacement current. Thus the maximum conduction current is $\boxed{35\mu\text{A}}$.

(*b*) The charge on the pages is given by $Q = CV = C\mathscr{E}_0 \cos\omega t$. The current is the derivative of this.

$$I = \frac{dQ}{dt} = -\omega C\mathscr{E}_0 \sin\omega t \;\; ; \;\; I_{\max} = \omega C\mathscr{E}_0 \;\; \rightarrow$$

$$\mathscr{E}_0 = \frac{I_{\max}}{\omega \text{C}} = \frac{I_{\max} d}{2\pi f \varepsilon_0 A} = \frac{\left(35\times10^{-6}\,\text{A}\right)\left(1.6\times10^{-3}\,\text{m}\right)}{2\pi\left(76.0\,\text{Hz}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\pi\left(0.025\text{m}\right)^2}$$

$$= 6749\,\text{V} \approx \boxed{6700\,\text{V}}$$

(*c*) From Eq. 31-3, $I_{\text{D}} = \varepsilon_0 \dfrac{d\Phi_E}{dt}$.

$$I_{\text{D}} = \varepsilon_0 \frac{d\Phi_E}{dt} \;\; \rightarrow \;\; \left(\frac{d\Phi_E}{dt}\right)_{\max} = \frac{\left(I_{\text{D}}\right)_{\max}}{\varepsilon_0} = \frac{35\times10^{-6}\,\text{A}}{8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2} = \boxed{4.0\times10^6\,\text{V}\bullet\text{m/s}}$$

7. (*a*) We follow the development and geometry given in Example 31-1, using R for the radial distance. The electric field between the plates is given by $E = \dfrac{V}{d}$, where *d* is the distance between the plates.

$$\oint \vec{\mathbf{B}}\bullet d\vec{\boldsymbol{\ell}} = \mu_0\varepsilon_0 \frac{d\Phi_E}{dt} \;\; \rightarrow \;\; B\left(2\pi R_{\text{path}}\right) = \mu_0\varepsilon_0 \frac{d\left(\pi R_{\text{flux}}^2 E\right)}{dt}$$

The subscripts are used on the radial variable because there might not be electric field flux through the entire area bounded by the amperian path. The electric field between the plates is given by $E = \dfrac{V}{d} = \dfrac{V_0 \sin\left(2\pi ft\right)}{d}$, where *d* is the distance between the plates.

$$B\left(2\pi R_{\text{path}}\right) = \mu_0\varepsilon_0 \frac{d\left(\pi R_{\text{flux}}^2 E\right)}{dt} \;\; \rightarrow$$

$$B = \frac{\mu_0\varepsilon_0\pi R_{\text{flux}}^2}{2\pi R_{\text{path}}}\frac{d\left(E\right)}{dt} = \frac{\mu_0\varepsilon_0\pi R_{\text{flux}}^2}{2\pi R_{\text{path}}}\frac{2\pi fV_0}{d}\cos\left(2\pi ft\right) = \frac{\mu_0\varepsilon_0 R_{\text{flux}}^2}{R_{\text{path}}}\frac{\pi fV_0}{d}\cos\left(2\pi ft\right)$$

We see that the functional form of the magnetic field is $\boxed{B = B_0\left(R\right)\cos\left(2\pi ft\right)}$.

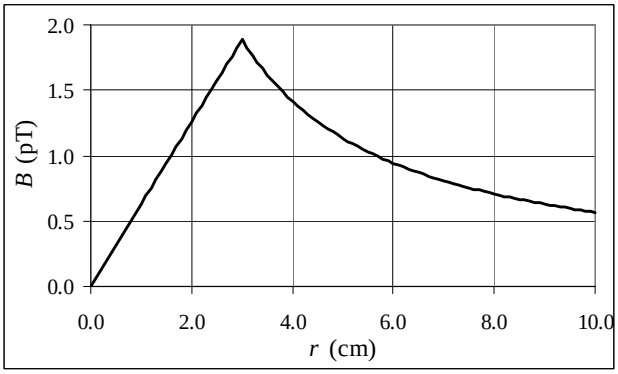
(*b*) If $R \le R_0$, then there is electric flux throughout the area bounded by the amperian loop, and so $R_{\text{path}} = R_{\text{flux}} = R$.

$$B_0\left(R \le R_0\right) = \frac{\mu_0\varepsilon_0 R_{\text{flux}}^2}{R_{\text{path}}}\frac{\pi f V_0}{d} = \mu_0\varepsilon_0\frac{\pi f V_0}{d}R = \frac{\pi\left(60\,\text{Hz}\right)\left(150\,\text{V}\right)}{\left(3.00\times10^8\,\text{m/s}\right)^2\left(5.0\times10^{-3}\,\text{m}\right)}R$$



$$= \left(6.283\times10^{-11}\,\text{T/m}\right)R \approx \boxed{\left(6.3\times10^{-11}\,\text{T/m}\right)R}$$

If $R > R_0$, then there is electric flux only out a radial distance of R_0. Thus $R_{\text{path}} = R$ and $R_{\text{flux}} = R_0$.

$$B_0\left(R > R_0\right) = \frac{\mu_0\varepsilon_0 R_{\text{flux}}^2}{R_{\text{path}}}\frac{\pi f V_0}{d} = \mu_0\varepsilon_0\frac{\pi f V_0 R_0^2}{d}\frac{1}{R} = \frac{\pi\left(60\,\text{Hz}\right)\left(150\,\text{V}\right)\left(0.030\,\text{m}\right)^2}{\left(3.00\times10^8\,\text{m/s}\right)^2\left(5.0\times10^{-3}\,\text{m}\right)}\frac{1}{R}$$

$$= \left(5.655\times10^{-14}\,\text{T•m}\right)\frac{1}{R} \approx \boxed{\left(5.7\times10^{-14}\,\text{T•m}\right)\frac{1}{R}}$$

(*c*) See the adjacent graph. Note that the magnetic field is continuous at the transition from "inside" to "outside" the capacitor radius. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH31.XLS," on tab "Problem 31.7c."

8. Use Eq. 31-11 with $v = c$.

$$\frac{E_0}{B_0} = c \quad\rightarrow\quad B_0 = \frac{E_0}{c} = \frac{0.57\times10^{-4}\,\text{V/m}}{3.00\times10^8\,\text{m/s}} = \boxed{1.9\times10^{-13}\,\text{T}}$$

9. Use Eq. 31-11 with $v = c$.

$$\frac{E_0}{B_0} = c \quad\rightarrow\quad E_0 = B_0 c = \left(12.5\times10^{-9}\,\text{T}\right)\left(3.00\times10^8\,\text{m/s}\right) = \boxed{3.75\,\text{V/m}}$$

10. The frequency of the two fields must be the same: $\boxed{80.0\,\text{kHz}}$. The rms strength of the electric field can be found from Eq. 31-11 with $v = c$.

$$E_{\text{rms}} = cB_{\text{rms}} = \left(3.00\times10^8\,\text{m/s}\right)\left(7.75\times10^{-9}\,\text{T}\right) = \boxed{2.33\,\text{V/m}}$$

The electric field is perpendicular to both the direction of travel and the magnetic field, so the electric field oscillates along the $\boxed{\text{horizontal north-south line.}}$

11. (*a*) If we write the argument of the cosine function as $kz + \omega t = k(z + ct)$, we see that the wave is traveling in the $\boxed{-z\text{ direction}}$, or $\boxed{-\hat{\mathbf{k}}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) $\vec{\mathbf{E}}$ and $\vec{\mathbf{B}}$ are perpendicular to each other and to the direction of propagation. At the origin, the electric field is pointing in the positive *x* direction. Since $\vec{\mathbf{E}}\times\vec{\mathbf{B}}$ must point in the negative *z* direction, $\vec{\mathbf{B}}$ must point in the the $\boxed{-y \text{ direction}}$, or $\boxed{-\hat{\mathbf{j}}}$. The magnitude of the magnetic field is found from Eq. 31-11 as $B_0 = \boxed{E_0/c}$.

12. The wave equation to be considered is $v^2\dfrac{\partial^2 E}{\partial x^2} = \dfrac{\partial^2 E}{\partial t^2}$.

(*a*) Given $E(x,t) = Ae^{-\alpha(x-vt)^2}$.

$$\frac{\partial E}{\partial x} = Ae^{-\alpha(x-vt)^2}\left[-2\alpha(x-vt)\right]$$

$$\frac{\partial^2 E}{\partial x^2} = Ae^{-\alpha(x-vt)^2}(-2\alpha) + Ae^{-\alpha(x-vt)^2}\left[-2\alpha(x-vt)\right]^2 = -2\alpha Ae^{-\alpha(x-vt)^2}\left[1-2\alpha(x-vt)^2\right]$$

$$\frac{\partial E}{\partial t} = Ae^{-\alpha(x-vt)^2}\left[-2\alpha(x-vt)(-v)\right] = Ae^{-\alpha(x-vt)^2}\left[2\alpha v(x-vt)\right]$$

$$\frac{\partial^2 E}{\partial t^2} = Ae^{-\alpha(x-vt)^2}(-2\alpha v^2) + Ae^{-\alpha(x-vt)^2}\left[2\alpha v(x-vt)\right]^2 = -2\alpha v^2 Ae^{-\alpha(x-vt)^2}\left[1-2\alpha(x-vt)^2\right]$$

We see that $v^2\dfrac{\partial^2 E}{\partial x^2} = \dfrac{\partial^2 E}{\partial t^2}$, and so the wave equation is satisfied.

(*b*) Given $E(x,t) = Ae^{-(\alpha x^2 - vt)}$.

$$\frac{\partial E}{\partial x} = Ae^{-(\alpha x^2-vt)}(-2\alpha x)$$

$$\frac{\partial^2 E}{\partial x^2} = Ae^{-(\alpha x^2-vt)}(-2\alpha) + Ae^{-(\alpha x^2-vt)}(-2\alpha x)^2 = -2\alpha Ae^{-(\alpha x^2-vt)}\left[1-2\alpha x^2\right]$$

$$\frac{\partial E}{\partial t} = Ave^{-(\alpha x^2-vt)} \;;\; \frac{\partial^2 E}{\partial t^2} = Av^2 e^{-(\alpha x^2-vt)}$$

This does NOT satisfy $v^2\dfrac{\partial^2 E}{\partial x^2} = \dfrac{\partial^2 E}{\partial t^2}$, since $-2\alpha v^2 Ae^{-(\alpha x^2-vt)}\left[1-2\alpha x^2\right] \neq Av^2 e^{-(\alpha x^2-vt)}$ in general.

13. Use Eq. 31-14 to find the frequency of the microwave.

$$c = \lambda f \;\rightarrow\; f = \frac{c}{\lambda} = \frac{(3.00\times10^8\ \text{m/s})}{(1.50\times10^{-2}\ \text{m})} = \boxed{2.00\times10^{10}\ \text{Hz}}$$

14. Use Eq. 31-14 to find the wavelength and frequency.

(*a*) $c = \lambda f \;\rightarrow\; \lambda = \dfrac{c}{f} = \dfrac{(3.000\times10^8\ \text{m/s})}{(25.75\times10^9\ \text{Hz})} = \boxed{1.165\times10^{-2}\ \text{m}}$

(*b*) $c = \lambda f \;\rightarrow\; f = \dfrac{c}{\lambda} = \dfrac{(3.00\times10^8\ \text{m/s})}{(0.12\times10^{-9}\ \text{m})} = \boxed{2.5\times10^{18}\ \text{Hz}}$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

15. Use the relationship that $d = vt$ to find the time.

$$d = vt \quad \rightarrow \quad t = \frac{d}{v} = \frac{\left(1.50 \times 10^{11}\,\text{m}\right)}{\left(3.00 \times 10^{8}\,\text{m/s}\right)} = 5.00 \times 10^{2}\,\text{s} = \boxed{8.33\,\text{min}}$$

16. Use Eq. 31-14 to find the wavelength.

$$c = \lambda f \quad \rightarrow \quad \lambda = \frac{c}{f} = \frac{\left(3.00 \times 10^{8}\,\text{m/s}\right)}{\left(8.56 \times 10^{14}\,\text{Hz}\right)} = \boxed{3.50 \times 10^{-7}\,\text{m}} = 311\,\text{nm}$$

This wavelength is just outside the violet end of the visible region, so it is ultraviolet.

17. (*a*) Use Eq. 31-14 to find the wavelength.

$$c = \lambda f \quad \rightarrow \quad \lambda = \frac{c}{f} = \frac{\left(3.00 \times 10^{8}\,\text{m/s}\right)}{\left(1.00 \times 10^{3}\,\text{Hz}\right)} = \boxed{3.00 \times 10^{5}\,\text{m}}$$

(*b*) Again use Eq. 31-14, with the speed of sound in place of the speed of light.

$$v = \lambda f \quad \rightarrow \quad \lambda = \frac{v}{f} = \frac{\left(341\,\text{m/s}\right)}{\left(1.00 \times 10^{3}\,\text{Hz}\right)} = \boxed{0.341\,\text{m}}$$

(*c*) No, you cannot hear a 1000-Hz EM wave. It takes a pressure wave to excite the auditory system. However, if you applied the 1000-Hz EM wave to a speaker, you could hear the 1000-Hz pressure wave.

18. The length of the pulse is $\Delta d = c\Delta t$. Use this to find the number of wavelengths in a pulse.

$$N = \frac{\left(c\Delta t\right)}{\lambda} = \frac{\left(3.00 \times 10^{8}\,\text{m/s}\right)\left(38 \times 10^{-12}\,\text{s}\right)}{\left(1062 \times 10^{-9}\,\text{m}\right)} = 10734 \approx \boxed{11{,}000\ \text{wavelengths}}$$

If the pulse is to be only one wavelength long, then its time duration is the period of the wave, which is the reciprocal of the wavelength.

$$T = \frac{1}{f} = \frac{\lambda}{c} = \frac{\left(1062 \times 10^{-9}\,\text{m}\right)}{\left(3.00 \times 10^{8}\,\text{m/s}\right)} = \boxed{3.54 \times 10^{-15}\,\text{s}}$$

19. (*a*) The radio waves travel at the speed of light, and so $\Delta d = v\Delta t$. The distance is found from the radii of the orbits. For Mars when nearest the Earth, the radii should be subtracted.

$$\Delta t = \frac{\Delta d}{c} = \frac{\left(227.9 \times 10^{9}\,\text{m} - 149.6 \times 10^{9}\,\text{m}\right)}{\left(3.000 \times 10^{8}\,\text{m/s}\right)} = \boxed{261\,\text{s}}$$

(*b*) For Mars when farthest from Earth, the radii should be subtracted.

$$\Delta t = \frac{\Delta d}{c} = \frac{\left(227.9 \times 10^{9}\,\text{m} + 149.6 \times 10^{9}\,\text{m}\right)}{\left(3.000 \times 10^{8}\,\text{m/s}\right)} = \boxed{1260\,\text{s}}$$

20. (*a*) The general form of a plane wave is given in Eq. 31-7. For this wave, $E_x = E_0 \sin\left(kz - \omega t\right)$.

$$\lambda = \frac{2\pi}{k} = \frac{2\pi}{0.077\,\text{m}^{-1}} = 81.60\,\text{m} \approx \boxed{82\,\text{m}}$$

$$f = \frac{\omega}{2\pi} = \frac{2.3 \times 10^{7}\ \text{rad/s}}{2\pi} = 3.661 \times 10^{6}\,\text{Hz} \approx \boxed{3.7\,\text{MHz}}$$

Note that $\lambda f = \left(81.60\,\text{m}\right)\left(3.661 \times 10^{6}\,\text{Hz}\right) = 2.987 \times 10^{8}\,\text{m/s} \approx c$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The magnitude of the magnetic field is given by $B_0 = E_0/c$. The wave is traveling in the $\hat{\mathbf{k}}$ direction, and so the magnetic field must be in the $\hat{\mathbf{j}}$ direction, since the direction of travel is given by the direction of $\vec{\mathbf{E}} \times \vec{\mathbf{B}}$.

$$B_0 = \frac{E_0}{c} = \frac{225\,\text{V/m}}{3.00\times10^8\,\text{m/s}} = 7.50\times10^{-7}\,\text{T} \quad \rightarrow$$

$$\vec{\mathbf{B}} = \boxed{\hat{\mathbf{j}}\left(7.50\times10^{-7}\,\text{T}\right)\sin\left[\left(0.077\text{m}^{-1}\right)z - \left(2.3\times10^7\,\text{rad/s}\right)t\right]}$$

21. The eight-sided mirror would have to rotate 1/8 of a revolution for the succeeding mirror to be in position to reflect the light in the proper direction. During this time the light must travel to the opposite mirror and back.

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{\frac{1}{8}(2\pi\,\text{rad})}{(2\Delta x/c)} = \frac{(\pi\,\text{rad})c}{8\Delta x} = \frac{(\pi\,\text{rad})(3.00\times10^8\,\text{m/s})}{8(35\times10^3\,\text{m})} = \boxed{3400\ \text{rad/s}}\ (3.2\times10^4\ \text{rev/min})$$

22. The average energy transferred across unit area per unit time is the average magnitude of the Poynting vector, and is given by Eq. 31-19a.

$$\overline{S} = \tfrac{1}{2}\varepsilon_0 cE_0^2 = \tfrac{1}{2}\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(3.00\times10^8\,\text{m/s}\right)\left(0.0265\,\text{V/m}\right) = \boxed{9.32\times10^{-7}\,\text{W/m}^2}$$

23. The energy per unit area per unit time is given by the magnitude of the Poynting vector. Let ΔU represent the energy that crosses area A in a time ΔT.

$$S = \frac{cB_{\text{rms}}^2}{\mu_0} = \frac{\Delta U}{A\Delta t} \quad \rightarrow$$

$$\Delta t = \frac{\mu_0 \Delta U}{AcB_{\text{rms}}^2} = \frac{\left(4\pi\times10^{-7}\,\text{T}\cdot\text{m/A}\right)(335\,\text{J})}{\left(1.00\times10^{-4}\,\text{m}^2\right)\left(3.00\times10^8\,\text{m/s}\right)\left(22.5\times10^{-9}\,\text{T}\right)^2} = 0.194\,\text{W/m}^2$$

$$= \boxed{2.77\times10^7\,\text{s}} \approx 321\ \text{days}$$

24. The energy per unit area per unit time is given by the magnitude of the Poynting vector. Let ΔU represent the energy that crosses area A in a time Δt.

$$S = c\varepsilon_0 E_{\text{rms}}^2 = \frac{\Delta U}{A\Delta t} \quad \rightarrow$$

$$\frac{\Delta U}{\Delta t} = c\varepsilon_0 E_{\text{rms}}^2 A$$

$$= \left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(0.0328\,\text{V/m}\right)^2\left(1.00\times10^{-4}\,\text{m}^2\right)(3600\,\text{s/h})$$

$$= \boxed{1.03\times10^{-6}\,\text{J/h}}$$

25. The intensity is the power per unit area, and also is the time averaged value of the Poynting vector. The area is the surface area of a sphere, since the wave is spreading spherically.

$$\overline{S} = \frac{P}{A} = \frac{(1500\,\text{W})}{\left[4\pi(5.0\,\text{m})^2\right]} = 4.775\,\text{W/m}^2 \approx \boxed{4.8\,\text{W/m}^2}$$

$$\overline{S} = c\varepsilon_0 E_{\text{rms}}^2 \quad \rightarrow \quad E_{\text{rms}} = \sqrt{\frac{\overline{S}}{c\varepsilon_0}} = \sqrt{\frac{4.775\,\text{W/m}^2}{\left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}} = \boxed{42\,\text{V/m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

26. (*a*) We find *E* using Eq. 31-11 with $v = c$.

$$E = cB = \left(3.00\times10^{8}\,\text{m/s}\right)\left(2.5\times10^{-7}\,\text{T}\right) = \boxed{75\,\text{V/m}}$$

(*b*) The average power per unit area is given by the Poynting vector, from Eq. 31-19a.

$$\overline{I} = \frac{E_0 B_0}{(2\mu_0)} = \frac{(75\,\text{V/m})\left(2.5\times10^{-7}\,\text{T}\right)}{\left[2\left(4\pi\times10^{-7}\,\text{N}\bullet\text{s}^2/\text{C}^2\right)\right]} = \boxed{7.5\,\text{W/m}^2}$$

27. From Eq. 31-16b, the instantaneous energy density is $u = \varepsilon_0 E^2$. From Eq. 31-17, we see that this instantaneous energy density is also given by S/c. The time-averaged value is therefore $\overline{S}/c$. Multiply that times the volume to get the energy.

$$U = uV = \frac{\overline{S}}{c}V = \frac{1350\,\text{W/m}^2}{3.00\times10^{8}\,\text{m/s}}\left(1.00\,\text{m}^3\right) = \boxed{4.50\times10^{-6}\,\text{J}}$$

28. The power output per unit area is the intensity, and also is the magnitude of the Poynting vector. Use Eq. 31-19a with rms values.

$$S = \frac{P}{A} = c\varepsilon_0 E_{\text{rms}}^2 \quad \rightarrow$$

$$E_{\text{rms}} = \sqrt{\frac{P}{Ac\varepsilon_0}} = \sqrt{\frac{0.0158\,\text{W}}{\pi\left(1.00\times10^{-3}\,\text{m}\right)^2\left(3.00\times10^{8}\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}}$$

$$= 1376.3\,\text{V/m} \approx \boxed{1380\,\text{V/m}}$$

$$B_{\text{rms}} = \frac{E_{\text{rms}}}{c} = \frac{1376.3\,\text{V/m}}{3.00\times10^{8}\,\text{m/s}} = \boxed{4.59\times10^{-6}\,\text{T}}$$

29. The radiation from the Sun has the same intensity in all directions, so the rate at which it reaches the Earth is the rate at which it passes through a sphere centered at the Sun with a radius equal to the Earth's orbit radius. The $1350\,\text{W/m}^2$ is the intensity, or the magnitude of the Poynting vector.

$$S = \frac{P}{A} \quad \rightarrow \quad P = SA = 4\pi R^2 S = 4\pi\left(1.496\times10^{11}\,\text{m}\right)^2\left(1350\,\text{W/m}^2\right) = \boxed{3.80\times10^{26}\,\text{W}}$$

30. (*a*) The energy emitted in each pulse is the power output of the laser times the time duration of the pulse.

$$P = \frac{\Delta W}{\Delta t} \quad \rightarrow \quad \Delta W = P\Delta t = \left(1.8\times10^{11}\,\text{W}\right)\left(1.0\times10^{-9}\,\text{s}\right) = \boxed{180\,\text{J}}$$

(*b*) We find the rms electric field from the intensity, which is the power per unit area. That is also the magnitude of the Poynting vector. Use Eq. 31-19a with rms values.

$$S = \frac{P}{A} = c\varepsilon_0 E_{\text{rms}}^2 \quad \rightarrow$$

$$E_{\text{rms}} = \sqrt{\frac{P}{Ac\varepsilon_0}} = \sqrt{\frac{\left(1.8\times10^{11}\,\text{W}\right)}{\pi\left(2.2\times10^{-3}\,\text{m}\right)^2\left(3.00\times10^{8}\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}}$$

$$= \boxed{2.1\times10^{9}\,\text{V/m}}$$

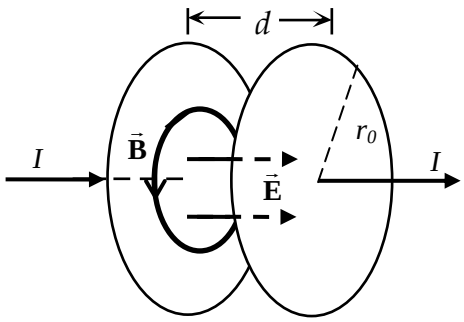
31. In each case, the required area is the power requirement of the device divided by 10% of the intensity of the sunlight.

(*a*) $A = \dfrac{P}{I} = \dfrac{50\times10^{-3}\,\text{W}}{100\,\text{W/m}^2} = 5\times10^{-4}\,\text{m}^2 = \boxed{5\,\text{cm}^2}$

A typical calculator is about 17 cm x 8 cm, which is about $140\,\text{cm}^2$. So yes, the solar panel can be mounted directly on the calculator.



(*b*) $A = \dfrac{P}{I} = \dfrac{1500\,\text{W}}{100\,\text{W/m}^2} = 15\,\text{m}^2 \approx \boxed{20\,\text{m}^2}$ (to one sig. fig.)

A house of floor area $1000\,\text{ft}^2$ would have on the order of $100\,\text{m}^2$ of roof area. So yes, a solar panel on the roof should be able to power the hair dryer.

(*c*) $A = \dfrac{P}{I} = \dfrac{20\,\text{hp}(746\,\text{W/hp})}{100\,\text{W/m}^2} = 149\,\text{m}^2 \approx \boxed{100\,\text{m}^2}$ (to one sig. fig.)

This would require a square panel of side length about 12 m. So no, this panel could not be mounted on a car and used for real-time power.

32. (*a*) Example 31-1 refers back to Example 21-13 and Figure 21-31. In that figure, and the figure included here, the electric field between the plates is to the right. The magnetic field is shown as counterclockwise circles. Take any point between the capacitor plates, and find the direction of $\vec{\mathbf{E}}\times\vec{\mathbf{B}}$. For instance, at the top of the circle shown in Figure 31-4, $\vec{\mathbf{E}}$ is toward the viewer, and $\vec{\mathbf{B}}$ is to the left. The cross product $\vec{\mathbf{E}}\times\vec{\mathbf{B}}$ points down, directly to the line connecting the center of the plates. Or take the rightmost point on the circle. $\vec{\mathbf{E}}$ is again toward the viewer, and $\vec{\mathbf{B}}$ is upwards. The cross product $\vec{\mathbf{E}}\times\vec{\mathbf{B}}$ points to the left, again directly to the line connecting the center of the plates. In cylindrical coordinates, $\vec{\mathbf{E}} = E\hat{\mathbf{k}}$ and $\vec{\mathbf{B}} = B\hat{\boldsymbol{\varphi}}$. The cross product $\hat{\mathbf{k}}\times\hat{\boldsymbol{\varphi}} = -\hat{\mathbf{r}}$.

(*b*) We evaluate the Poynting vector, and then integrate it over the curved cylindrical surface between the capacitor plates. The magnetic field (from Example 31-1) is $B = \frac{1}{2}\mu_0\varepsilon_0 r_0\dfrac{dE}{dt}$, evaluated at $r = r_0$. $\vec{\mathbf{E}}$ and $\vec{\mathbf{B}}$ are perpendicular to each other, so $\vec{\mathbf{S}} = \dfrac{1}{\mu_0}\vec{\mathbf{E}}\times\vec{\mathbf{B}} = \frac{1}{2}\varepsilon_0 r_0 E\dfrac{dE}{dt}$, inward. In calculating $\iint\vec{\mathbf{S}}\bullet d\vec{\mathbf{A}}$ for energy flow into the capacitor volume, note that both $\vec{\mathbf{S}}$ and $d\vec{\mathbf{A}}$ point inward, and that *S* is constant over the curved surface of the cylindrical volume.

$$\iint\vec{\mathbf{S}}\bullet d\vec{\mathbf{A}} = \iint S\,dA = S\iint dA = SA = S2\pi r_0 d = \tfrac{1}{2}\varepsilon_0 r_0 E\frac{dE}{dt}2\pi r_0 d = \varepsilon_0 d\pi r_0^2 E\frac{dE}{dt}$$

The amount of energy stored in the capacitor is the energy density times the volume of the capacitor. The energy density is given by Eq. 24-6, $u = \frac{1}{2}\varepsilon_0 E^2$, and the energy stored is the energy density times the volume of the capacitor. Take the derivative of the energy stored with respect to time.

$$U = u(\text{Volume}) = \tfrac{1}{2}\varepsilon_0 E^2\pi r_0^2 d \quad\rightarrow\quad \frac{dU}{dt} = \varepsilon_0 E\pi r_0^2 d\frac{dE}{dt}$$

We see that $\iint\vec{\mathbf{S}}\bullet d\vec{\mathbf{A}} = \dfrac{dU}{dt}$.

33. (*a*) The intensity from a point source is inversely proportional to the distance from the source.

$$\frac{I_{\text{Sun}}}{I_{\text{Star}}} = \frac{r^2_{\substack{\text{Star-}\\\text{Earth}}}}{r^2_{\substack{\text{Sun-}\\\text{Earth}}}} \quad \rightarrow \quad r_{\substack{\text{Star-}\\\text{Earth}}} = r_{\substack{\text{Sun-}\\\text{Earth}}}\sqrt{\frac{I_{\text{Sun}}}{I_{\text{Star}}}} = \left(1.496\times10^{11}\,\text{m}\right)\sqrt{\frac{1350\,\text{W/m}^2}{1\times10^{-23}\,\text{W/m}^2}}\left(\frac{1\,\text{ly}}{9.46\times10^{15}\,\text{m}}\right)$$

$$= 1.84\times10^{8}\,\text{ly} \approx \boxed{2\times10^{8}\,\text{ly}}$$

(*b*) Compare this distance to the galactic size.

$$\frac{r_{\substack{\text{Star-}\\\text{Earth}}}}{\text{galactic size}} = \frac{1.84\times10^{8}\,\text{ly}}{1\times10^{5}\,\text{ly}} = 1840 \approx \boxed{2000}$$

The distance to the star is about 2000 times the size of our galaxy.

34. We assume the light energy is all absorbed, and so use Eq. 31-21a.

$$P = \frac{\overline{S}}{c} = \frac{\dfrac{75\,\text{W}}{4\pi\left(8.0\times10^{-2}\,\text{m}\right)^2}}{\left(3.00\times10^{8}\,\text{m/s}\right)} = 3.108\times10^{-6}\,\text{N/m}^2 \approx \boxed{3.1\times10^{-6}\,\text{N/m}^2.}$$

The force is pressure times area. We approximate the area of a fingertip to be 1.0 cm^2.

$$F = PA = \left(3.108\times10^{-6}\,\text{N/m}^2\right)\left(1.0\times10^{-4}\,\text{m}^2\right) = \boxed{3.1\times10^{-10}\,\text{N}}$$

35. The acceleration of the cylindrical particle will be the force on it (due to radiation pressure) divided by its mass. The light is delivering electromagnetic energy to an area *A* at a rate of $\frac{dU}{dt} = 1.0\,\text{W}$. That power is related to the average magnitude of the Poynting vector by $\overline{S} = \frac{dU/dt}{A}$. From Eq. 31-21a, that causes a pressure on the particle of $P = \frac{\overline{S}}{c}$, and the force due to that pressure is $F_{\text{laser}} = PA$. Combine these relationships with Newton's second law to calculate the acceleration. The mass of the particle is its volume times the density of water.

$$F_{\text{laser}} = PA = \frac{\overline{S}}{c}A = \frac{1}{c}\frac{dU}{dt} = ma = \rho_{\text{H}_2\text{O}}\pi r^2 ra \quad \rightarrow$$

$$a = \frac{dU/dt}{c\rho_{\text{H}_2\text{O}}\pi r^3} = \frac{\left(1.0\,\text{W}\right)}{\left(3.00\times10^{8}\,\text{m/s}\right)\left(1000\,\text{kg/m}^2\right)\pi\left(5\times10^{-7}\,\text{m}\right)^3} = \boxed{8\times10^{6}\,\text{m/s}^2}$$

36. (*a*) The light is delivering electromagnetic energy to an area *A* of the suit at a rate of $\frac{dU}{dt} = 3.0\,\text{W}$. That power is related to the average magnitude of the Poynting vector by $\overline{S} = \frac{dU/dt}{A}$. From Eq. 31-21b, that causes a pressure on the suit of $P = \frac{2\overline{S}}{c}$, and the force due to that pressure is $F_{\text{laser}} = PA$. Combine these relationships to calculate the force.

$$F_{\text{laser}} = PA = \frac{2\overline{S}}{c}A = \frac{2}{c}\frac{dU}{dt} = \frac{2\left(3.0\,\text{W}\right)}{3.00\times10^{8}\,\text{m/s}} = \boxed{2.0\times10^{-8}\,\text{N}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Use Newton's law of universal gravitation, Eq. 6-1, to estimate the gravitational force. We take the 20 m distance as having 2 significant figures.

$$F_{\text{grav}} = G\frac{m_{\text{shuttle}}m_{\text{astronaut}}}{r^2} = \left(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\frac{\left(1.03\times10^5\,\text{kg}\right)\left(120\,\text{kg}\right)}{\left(20\,\text{m}\right)^2}$$

$$= 2.061\times10^{-6}\,\text{N} \approx \boxed{2.1\times10^{-6}\,\text{N}}$$

(*c*) The gravity force is larger, by a factor of approximately 100.

37. The intensity from a point source is inversely proportional to the distance from the source.

$$\frac{I_{\text{Earth}}}{I_{\text{Jupiter}}} = \frac{r^2_{\text{Sun-Jupiter}}}{r^2_{\text{Sun-Earth}}} = \frac{\left(7.78\times10^{11}\,\text{m}\right)^2}{\left(1.496\times10^{11}\,\text{m}\right)^2} = 27.0$$

So it would take an area of $\boxed{27\,\text{m}^2}$ at Jupiter to collect the same radiation as a 1.0-m^2 solar panel at the Earth.

38. Use Eq. 31-14. Note that the higher frequencies have the shorter wavelengths.

(*a*) For FM radio we have the following.

$$\lambda = \frac{c}{f} = \frac{\left(3.00\times10^8\,\text{m/s}\right)}{\left(1.08\times10^8\,\text{Hz}\right)} = \boxed{2.78\,\text{m}} \text{ to } \lambda = \frac{c}{f} = \frac{\left(3.00\times10^8\,\text{m/s}\right)}{\left(8.8\times10^7\,\text{Hz}\right)} = \boxed{3.41\,\text{m}}$$

(*b*) For AM radio we have the following.

$$\lambda = \frac{c}{f} = \frac{\left(3.00\times10^8\,\text{m/s}\right)}{\left(1.7\times10^6\,\text{Hz}\right)} = \boxed{180\,\text{m}} \text{ to } \lambda = \frac{c}{f} = \frac{\left(3.00\times10^8\,\text{m/s}\right)}{\left(5.35\times10^5\,\text{Hz}\right)} = \boxed{561\,\text{m}}$$

39. Use Eq. 31-14.

$$\lambda = \frac{c}{f} = \frac{\left(3.00\times10^8\,\text{m/s}\right)}{\left(1.9\times10^9\,\text{Hz}\right)} = \boxed{0.16\,\text{m}}$$

40. The resonant frequency of an *LC* circuit is given by $f = \frac{2\pi}{\omega} = \frac{2\pi}{\sqrt{LC}}$. We assume the inductance is constant, and form the ratio of the two frequencies.

$$\frac{f_1}{f_2} = \frac{\frac{2\pi}{\sqrt{LC_1}}}{\frac{2\pi}{\sqrt{LC_2}}} = \sqrt{\frac{C_2}{C_1}} \quad\rightarrow\quad C_2 = \left(\frac{f_1}{f_2}\right)^2 C_1 = \left(\frac{550\,\text{kHz}}{1610\,\text{kHz}}\right)^2 \left(2200\,\text{pF}\right) = \boxed{260\,\text{pF}}$$

41. The resonant frequency of an *LC* circuit is given by $f = \frac{\omega}{2\pi} = \frac{1}{2\pi\sqrt{LC}}$. Solve for the inductance.

$$f = \frac{1}{2\pi\sqrt{LC}} \quad\rightarrow\quad L = \frac{1}{4\pi^2 f^2 C}$$

$$L_1 = \frac{1}{4\pi^2 f_1^2 C} = \frac{1}{4\pi^2\left(88\times10^6\,\text{Hz}\right)^2\left(620\times10^{-12}\,\text{F}\right)} = 5.3\times10^{-9}\,\text{H}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$L_2 = \frac{1}{4\pi^2 f_2^2 C} = \frac{1}{4\pi^2 \left(108\times10^6\,\text{Hz}\right)^2 \left(620\times10^{-12}\,\text{F}\right)} = 3.5\times10^{-9}\,\text{H}$$

The range of inductances is $\boxed{3.5\times10^{-9}\,\text{H} \le L \le 5.3\times10^{-9}\,\text{H}}$

42. The rms electric field strength of the beam can be found from the Poynting vector.

$$S = \frac{P}{A} = c\varepsilon_0 E_{\text{rms}}^2 \quad \rightarrow$$

$$E_{\text{rms}} = \sqrt{\frac{P}{Ac\varepsilon_0}} = \sqrt{\frac{1.2\times10^4\,\text{W}}{\pi\left(750\,\text{m}\right)^2\left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}} = \boxed{1.6\,\text{V/m}}$$

43. The electric field is found from the desired voltage and the length of the antenna. Then use that electric field to calculate the magnitude of the Poynting vector.

$$E_{\text{rms}} = \frac{V_{\text{rms}}}{d} = \frac{1.00\times10^{-3}\,\text{V}}{1.60\,\text{m}} = \boxed{6.25\times10^{-4}\,\text{V/m}}$$

$$S = c\varepsilon_0 E_{\text{rms}}^2 = c\varepsilon_0 \frac{V_{\text{rms}}^2}{d^2} = \left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\frac{\left(1.00\times10^{-3}\,\text{V}\right)^2}{\left(1.60\,\text{m}\right)^2}$$

$$= \boxed{1.04\times10^{-9}\,\text{W/m}^2}$$

44. We ignore the time for the sound to travel to the microphone. Find the difference between the time for sound to travel to the balcony and for a radio wave to travel 3000 km.

$$\Delta t = t_{\text{radio}} - t_{\text{sound}} = \left(\frac{d_{\text{radio}}}{c}\right) - \left(\frac{d_{\text{sound}}}{v_{\text{sound}}}\right) = \left(\frac{3\times10^6\,\text{m}}{3.00\times10^8\,\text{m/s}}\right) - \left(\frac{50\,\text{m}}{343\,\text{m/s}}\right) = -0.14\,\text{s},$$

so the $\boxed{\text{person at the radio hears the voice 0.14 s sooner.}}$

45. The length is found from the speed of light and the duration of the burst.

$$d = ct = \left(3.00\times10^8\,\text{m/s}\right)\left(10^{-8}\,\text{s}\right) = \boxed{3\,\text{m}}$$

46. The time travel delay is the distance divided by the speed of radio waves (which is the speed of light).

$$t = \frac{d}{c} = \frac{3\times10^6\,\text{m}}{3.00\times10^8\,\text{m/s}} = \boxed{0.01\,\text{s}}$$

47. The time consists of the time for the radio signal to travel to Earth and the time for the sound to travel from the loudspeaker. We use 343 m/s for the speed of sound.

$$t = t_{\text{radio}} + t_{\text{sound}} = \left(\frac{d_{\text{radio}}}{c}\right) + \left(\frac{d_{\text{sound}}}{v_{\text{sound}}}\right) = \left(\frac{3.84\times10^8\,\text{m}}{3.00\times10^8\,\text{m/s}}\right) + \left(\frac{25\,\text{m}}{343\,\text{m/s}}\right) = \boxed{1.35\,\text{s}}$$

Note that about 5% of the time is for the sound wave.

48. (*a*) The rms value of the associated electric field is found from Eq. 24-6.

$$u = \tfrac{1}{2}\varepsilon_0 E^2 = \varepsilon_0 E_{\text{rms}}^2 \quad \rightarrow \quad E_{\text{rms}} = \sqrt{\frac{u}{\varepsilon_0}} = \sqrt{\frac{4\times10^{-14}\,\text{J/m}^3}{8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2}} = 0.0672\,\text{V/m} \approx \boxed{0.07\,\text{V/m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) A comparable value can be found using the magnitude of the Poynting vector.

$$\overline{S} = \varepsilon_0 c E_{\text{rms}}^2 = \frac{P}{4\pi r^2} \quad \rightarrow$$

$$r = \frac{1}{E_{\text{rms}}}\sqrt{\frac{P}{4\pi\varepsilon_0 c}} = \frac{1}{0.0672\,\text{V/m}}\sqrt{\frac{7500\,\text{W}}{4\pi\left(8.85\times10^{-12}\,\text{C}^2/\text{n}\bullet\text{m}^2\right)\left(3.00\times10^8\,\text{m/s}\right)}}$$

$$= 7055\,\text{m} \approx \boxed{7\,\text{km}}$$

49. The light has the same intensity in all directions, so use a spherical geometry centered on the source to find the value of the Poynting vector. Then use Eq. 31-19a to find the magnitude of the electric field, and Eq. 31-11 with $v = c$ to find the magnitude of the magnetic field.

$$S = \frac{P_0}{A} = \frac{P_0}{4\pi r^2} = \tfrac{1}{2} c\varepsilon_0 E_0^2 \quad \rightarrow$$

$$E_0 = \sqrt{\frac{P_0}{2\pi r^2 c\varepsilon_0}} = \sqrt{\frac{(75\,\text{W})}{2\pi(2.00\,\text{m})^2\left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{n}\bullet\text{m}^2\right)}} = 33.53\,\text{V/m}$$

$$\approx \boxed{34\,\text{V/m}}$$

$$B_0 = \frac{E_0}{c} = \frac{(33.53\,\text{V/m})}{\left(3.00\times10^8\,\text{m/s}\right)} = \boxed{1.1\times10^{-7}\,\text{T}}$$

50. The radiation from the Sun has the same intensity in all directions, so the rate at which energy passes through a sphere centered at the Sun is $P = S4\pi R^2$. This rate must be the same at any distance from the Sun. Use this fact to calculate the magnitude of the Poynting vector at Mars, and then use the Poynting vector to calculate the rms magnitude of the electric field at Mars.

$$S_{\text{Mars}}\left(4\pi R_{\text{Mars}}^2\right) = S_{\text{Earth}}\left(4\pi R_{\text{Earth}}^2\right) \quad \rightarrow \quad S_{\text{Mars}} = S_{\text{Earth}}\left(\frac{R_{\text{Earth}}^2}{R_{\text{Mars}}^2}\right) = c\varepsilon_0 E_{\substack{\text{rms}\\\text{Mars}}}^2 \quad \rightarrow$$

$$E_{\substack{\text{rms}\\\text{Mars}}} = \sqrt{\frac{S_{\text{Earth}}}{c\varepsilon_0}}\left(\frac{R_{\text{Earth}}}{R_{\text{Mars}}}\right) = \sqrt{\frac{1350\,\text{W/m}^2}{\left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{n}\bullet\text{m}^2\right)}}\left(\frac{1}{1.52}\right) = \boxed{469\,\text{V/m}}$$

51. The direction of the wave velocity is the direction of the cross product $\vec{\mathbf{E}}\times\vec{\mathbf{B}}$. "South" crossed into "west" gives the direction downward. The electric field is found from the Poynting vector, Eq. 31-19a, and then the magnetic field is found from Eq. 31-11 with $v = c$.

$$S = \tfrac{1}{2} c\varepsilon_0 E_0^{\,2} \quad \rightarrow$$

$$E_0 = \sqrt{\frac{2S}{c\varepsilon_0}} = \sqrt{\frac{2\left(560\,\text{W/m}^2\right)}{\left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{n}\bullet\text{m}^2\right)}} = 649\,\text{V/m} \approx \boxed{650\,\text{V/m}}$$

$$B_0 = \frac{E_0}{c} = \frac{(649\,\text{V/m})}{\left(3.00\times10^8\,\text{m/s}\right)} = \boxed{2.2\times10^{-6}\,\text{T}}$$

52. From the hint, we use Eq. 29-4, which says $\mathscr{E} = \mathscr{E}_0 \sin\omega t = NBA\omega\sin\omega t$. The intensity is given, and this can be used to find the magnitude of the magnetic field.

$$\overline{S} = \frac{E_{\text{rms}}B_{\text{rms}}}{\mu_0} = \frac{cB_{\text{rms}}^2}{\mu_0} \quad \rightarrow \quad B_{\text{rms}} = \sqrt{\frac{\mu_0\overline{S}}{c}} \;;\; \mathscr{E} = \mathscr{E}_0\sin\omega t = NBA\omega\sin\omega t \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\mathscr{E}_{\text{rms}} = NA\omega B_{\text{rms}} = NA\omega\sqrt{\frac{\mu_0 \bar{S}}{c}}$$

$$= (320)\pi(0.011\text{m})^2\, 2\pi\left(810\times10^3\,\text{Hz}\right)\sqrt{\frac{\left(4\pi\times10^{-7}\,\text{N}\cdot\text{s}^2/\text{C}^2\right)\left(1.0\times10^{-4}\,\text{W/m}^2\right)}{3.00\times10^8\,\text{m/s}}}$$

$$= \boxed{4.0\times10^{-4}\,\text{V}}$$

53. (*a*) Since intensity is energy per unit time per unit area, the energy is found by multiplying the intensity times the area of the antenna times the elapsed time.

$$U = IAt = \left(1.0\times10^{-13}\,\text{W/m}^2\right)\pi\left(\frac{0.33\text{m}}{2}\right)^2(6.0\,\text{h})(3600\,\text{s/h}) = \boxed{1.8\times10^{-10}\,\text{J}}$$

(*b*) The electric field amplitude can be found from the intensity, which is the magnitude of the Poynting vector. The magnitude of the magnetic field is then found from Eq. 31-11 with $v = c$.

$$\bar{I} = \tfrac{1}{2}\varepsilon_0 cE_0^2 \quad\rightarrow$$

$$E_0 = \sqrt{\frac{2\bar{I}}{\varepsilon_0 c}} = \sqrt{\frac{2\left(1.0\times10^{-13}\,\text{W/m}^2\right)}{\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(3.00\times10^8\,\text{m/s}\right)}} = 8.679\times10^{-6}\,\text{V/m}$$

$$\approx \boxed{8.7\times10^{-6}\,\text{V/m}}$$

$$B_0 = \frac{E_0}{c} = \frac{8.679\times10^{-6}\,\text{V/m}}{3.00\times10^8\,\text{m/s}} = \boxed{2.9\times10^{-14}\,\text{T}}$$

54. Use the relationship between average intensity (the magnitude of the Poynting vector) and electric field strength, as given by Eq. 31-19a. Also use the fact that intensity is power per unit area. We assume that the power is spherically symmetric about source.

$$\bar{S} = \tfrac{1}{2}\varepsilon_0 cE_0^{\,2} = \frac{P}{A} = \frac{P}{4\pi r^2} \quad\rightarrow$$

$$r = \sqrt{\frac{P}{2\pi\varepsilon_0 cE_0^{\,2}}} = \sqrt{\frac{25{,}000\,\text{W}}{2\pi\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(3.00\times10^8\,\text{m/s}\right)(0.020\,\text{V/m})^2}} = 61{,}200\,\text{m}$$

$$\approx \boxed{61\,\text{km}}$$

Thus, to receive the transmission one should be within 61 km of the station.

55. The light has the same intensity in all directions. Use a spherical geometry centered at the source with the definition of the Poynting vector.

$$S = \frac{P_0}{A} = \frac{P_0}{4\pi r^2} = \tfrac{1}{2}c\varepsilon_0 E_0^{\,2} = \tfrac{1}{2}c\left(\frac{1}{c^2\mu_0}\right)E_0 \quad\rightarrow\quad \tfrac{1}{2}c\left(\frac{1}{c^2\mu_0}\right)E_0 = \frac{P_0}{4\pi r^2} \quad\rightarrow\quad \boxed{E_0 = \sqrt{\frac{\mu_0 cP_0}{2\pi r^2}}}$$

56. (*a*) The radio waves have the same intensity in all directions. The power crossing a given area is the intensity times the area. The intensity is the total power through the area of a sphere centered at the source.

$$P = IA = \frac{P_0}{A_{\text{total}}}A = \frac{35{,}000\,\text{W}}{4\pi\left(1.0\times10^3\,\text{m}\right)^2}\left(1.0\,\text{m}^2\right) = 2.785\times10^{-3}\,\text{W} \approx \boxed{2.8\,\text{mW}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We find the rms value of the electric field from the intensity, which is the magnitude of the Poynting vector.

$$S = c\varepsilon_0 E_{\text{rms}}^2 = \frac{P_0}{4\pi r^2} \quad \rightarrow$$

$$E_{\text{rms}} = \sqrt{\frac{P_0}{4\pi r^2 c\varepsilon_0}} = \sqrt{\frac{35{,}000\,\text{W}}{4\pi\left(1.0\times10^3\,\text{m}\right)^2\left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}}$$

$$= 1.024\,\text{V/m} \approx \boxed{1.0\,\text{V/m}}$$

(*c*) The voltage over the length of the antenna is the electric field times the length of the antenna.

$$V_{\text{rms}} = E_{\text{rms}} d = \left(1.024\,\text{V/m}\right)\left(1.0\,\text{m}\right) = \boxed{1.0\,\text{V}}$$

(*d*) We calculate the electric field at the new distance, and then calculate the voltage.

$$E_{\text{rms}} = \sqrt{\frac{P_0}{4\pi r^2 c\varepsilon_0}} = \sqrt{\frac{35{,}000\,\text{W}}{4\pi\left(5.0\times10^4\,\text{m}\right)^2\left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)}}$$

$$= 2.048\times10^{-2}\,\text{V/m} \;\; ; \;\; V_{\text{rms}} = E_{\text{rms}} d = \left(2.048\times10^{-2}\,\text{V/m}\right)\left(1.0\,\text{m}\right) = \boxed{2.0\times10^{-2}\,\text{V}}$$

57. The power output of the antenna would be the intensity at a given distance from the antenna, times the area of a sphere surrounding the antenna. The intensity is the magnitude of the Poynting vector.

$$S = \tfrac{1}{2} c\varepsilon_0 E_0^2$$

$$P = 4\pi r^2 S = 2\pi r^2 c\varepsilon_0 E_0^2 = 2\pi\left(0.50\,\text{m}\right)^2\left(3.00\times10^8\,\text{m/s}\right)\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(3\times10^6\,\text{V/m}\right)^2$$

$$\approx \boxed{4\times10^{10}\,\text{W}}$$

This is many orders of magnitude higher than the power output of commercial radio stations, which are no higher than the 10's of kilowatts.

58. We calculate the speed of light in water according to the relationship given.

$$v_{\text{water}} = \frac{1}{\sqrt{K\varepsilon_0\mu_0}} = \frac{1}{\sqrt{K}}\frac{1}{\sqrt{\varepsilon_0\mu_0}} = \frac{1}{\sqrt{K}}c = \frac{1}{\sqrt{1.77}}\left(3.00\times10^8\,\text{m/s}\right) = \boxed{2.25\times10^8\,\text{m/s}}$$

$$\frac{v_{\text{water}}}{c} = \frac{\frac{1}{\sqrt{K}}c}{c} = \frac{1}{\sqrt{K}} = 0.752 = \boxed{75.2\%}$$

59. A standing wave has a node every half-wavelength, including the endpoints. For this wave, the nodes would occur at the spacing calculated here.

$$\tfrac{1}{2}\lambda = \tfrac{1}{2}\frac{c}{f} = \tfrac{1}{2}\frac{3.00\times10^8\,\text{m/s}}{2.45\times10^9\,\text{Hz}} = \boxed{0.0612\,\text{m}}$$

Thus there would be nodes at the following distances from a wall:

0, 6.12 cm, 12.2 cm, 18.4 cm, 24.5 cm, 30.6 cm, and 36.7 cm (approximately the other wall).

So there are 5 nodes, not counting the ones at (or near) the walls.

60. (*a*) Assume that the wire is of length ℓ and cross-sectional area *A*. There must be a voltage across the ends of the wire to make the current flow $(V = IR)$, and there must be an electric field associated with that voltage $(E = V/\ell)$. Use these relationships with the definition of displacement current, Eq. 31-3.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_D = \varepsilon_0 \frac{d\Phi_E}{dt} = \varepsilon_0 \frac{d(EA)}{dt} = \varepsilon_0 A \frac{dE}{dt} = \varepsilon_0 A \frac{d(V/\ell)}{dt} = \varepsilon_0 \frac{A}{\ell}\frac{dV}{dt} = \varepsilon_0 \rho \frac{A}{\rho \ell}\frac{d(IR)}{dt}$$

$$= \varepsilon_0 \rho \frac{1}{R} R \frac{dI}{dt} = \boxed{\varepsilon_0 \rho \frac{dI}{dt}}$$

(*b*) Calculate the displacement current found in part (*a*).

$$I_D = \varepsilon_0 \rho \frac{dI}{dt} = \left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(1.68\times10^{-8}\,\Omega\cdot\text{m}\right)\left(\frac{1.0\,\text{A}}{1.0\times10^{-3}\,\text{s}}\right)$$

$$= 1.4868\times10^{-16}\,\text{A} \approx \boxed{1.5\times10^{-16}\,\text{A}}$$

(*c*) From example 28-6, Ampere's law gives the magnetic field created by a cylinder of current as $B = \dfrac{\mu_0 I}{2\pi r}$ at a distance of *r* from the axis of the cylindrical wire. This is true whether the current is displacement current or steady current.

$$B_D = \frac{\mu_0 I_D}{2\pi r} = \frac{\left(4\pi\times10^{-7}\,\text{N}\cdot\text{s}^2/\text{C}^2\right)\left(1.486\times10^{-16}\,\text{A}\right)}{2\pi\left(1.0\times10^{-3}\,\text{m}\right)} = 2.97\times10^{-20}\,\text{T} \approx \boxed{3.0\times10^{-20}\,\text{T}}$$

$$\frac{B_D}{B_{\text{steady}}} = \frac{\dfrac{\mu_0 I_D}{2\pi r}}{\dfrac{\mu_0 I_{\text{steady}}}{2\pi r}} = \frac{I_D}{I_{\text{steady}}} = \frac{1.486\times10^{-16}\,\text{A}}{1.0\,\text{A}} = 1.486\times10^{-16} \approx \boxed{1.5\times10^{-16}}$$

61. (*a*) We note that $-\alpha x^2 - \beta^2 t^2 + 2\alpha\beta xt = -(\alpha x - \beta t)^2$ and so $E_y = E_0 e^{-(\alpha x-\beta t)^2} = E_0 e^{-\alpha^2\left(x-\frac{\beta}{\alpha}t\right)^2}$. Since the wave is of the form $f(x-vt)$, with $v = \beta/\alpha$, the wave is moving in the $\boxed{+x \text{ direction}}$.

(*b*) The speed of the wave is $v = \beta/\alpha = c$, and so $\boxed{\beta = \alpha c}$.

(*c*) The electric field is in the *y* direction, and the wave is moving in the *x* direction. Since $\vec{\mathbf{E}}\times\vec{\mathbf{B}}$ must be in the direction of motion, the magnetic field must be in the *z* direction. The magnitudes are related by $|\vec{\mathbf{B}}| = |\vec{\mathbf{E}}|/c$.

$$\boxed{B_z = \frac{E_0}{c} e^{-(\alpha x-\beta t)^2}}$$

62. (*a*) Use the $\sin A \pm \sin B = 2\sin\left(\dfrac{A\pm B}{2}\right)\cos\left(\dfrac{A\mp B}{2}\right)$ from page A-4 in Appendix A.

$$E_y = E_0\left[\sin(kx-\omega t) + \sin(kx+\omega t)\right]$$

$$= 2E_0 \sin\left(\frac{(kx-\omega t)+(kx+\omega t)}{2}\right)\cos\left(\frac{(kx-\omega t)-(kx+\omega t)}{2}\right) = 2E_0\sin(kx)\cos(-\omega t)$$

$$= \boxed{2E_0\sin(kx)\cos(\omega t)}$$

$$B_z = B_0\left[\sin(kx-\omega t) - \sin(kx+\omega t)\right]$$

$$= 2B_0 \sin\left(\frac{(kx-\omega t)-(kx+\omega t)}{2}\right)\cos\left(\frac{(kx-\omega t)+(kx+\omega t)}{2}\right) = 2B_0\sin(-\omega t)\cos(kx)$$

$$= \boxed{-2B_0\cos(kx)\sin(\omega t)}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The Poynting vector is given by $\vec{\mathbf{S}} = \frac{1}{\mu_0}\vec{\mathbf{E}} \times \vec{\mathbf{B}}$.

$$\vec{\mathbf{S}} = \frac{1}{\mu_0}\vec{\mathbf{E}} \times \vec{\mathbf{B}} = \frac{1}{\mu_0}\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 0 & 2E_0 \sin(kx)\cos(\omega t) & 0 \\ 0 & 0 & -2B_0 \cos(kx)\sin(\omega t) \end{vmatrix}$$

$$= \frac{1}{\mu_0}\hat{\mathbf{i}}\left[-4E_0 B_0 \sin(kx)\cos(kx)\sin(\omega t)\cos(\omega t)\right] = \boxed{-\frac{1}{\mu_0}\hat{\mathbf{i}}\, E_0 B_0 \sin(2kx)\sin(2\omega t)}$$

This is 0 for all times at positions where $\sin(2kx) = 0$.

$$\sin(2kx) = 0 \;\rightarrow\; 2kx = n\pi \;\rightarrow\; \boxed{x = \frac{n\pi}{2k},\ n = 0, \pm 1, \pm 2, \ldots}$$

63. (*a*) To show that $\vec{\mathbf{E}}$ and $\vec{\mathbf{B}}$ are perpendicular, calculate their dot product.

$$\vec{\mathbf{E}} \cdot \vec{\mathbf{B}} = \left[E_0 \sin(kx - \omega t)\hat{\mathbf{j}} + E_0 \cos(kx - \omega t)\hat{\mathbf{k}}\right] \cdot \left[B_0 \cos(kx - \omega t)\hat{\mathbf{j}} - B_0 \sin(kx - \omega t)\hat{\mathbf{k}}\right]$$

$$= E_0 \sin(kx - \omega t) B_0 \cos(kx - \omega t) - E_0 \cos(kx - \omega t) B_0 \sin(kx - \omega t) = 0$$

Since $\vec{\mathbf{E}} \cdot \vec{\mathbf{B}} \equiv 0$, $\vec{\mathbf{E}}$ and $\vec{\mathbf{B}}$ are perpendicular to each other at all times.

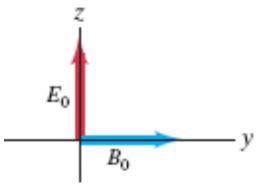
(*b*) The wave moves in the direction of the Poynting vector, which is given by $\vec{\mathbf{S}} = \frac{1}{\mu_0}\vec{\mathbf{E}} \times \vec{\mathbf{B}}$.

$$\vec{\mathbf{S}} = \frac{1}{\mu_0}\vec{\mathbf{E}} \times \vec{\mathbf{B}} = \frac{1}{\mu_0}\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 0 & E_0 \sin(kx - \omega t) & E_0 \cos(kx - \omega t) \\ 0 & B_0 \cos(kx - \omega t) & -B_0 \sin(kx - \omega t) \end{vmatrix}$$

$$= \frac{1}{\mu_0}\hat{\mathbf{i}}\left[-E_0 B_0 \sin^2(kx - \omega t) - E_0 B_0 \cos^2(kx - \omega t)\right] + \hat{\mathbf{j}}(0) + \hat{\mathbf{k}}(0) = -\frac{1}{\mu_0}E_0 B_0 \hat{\mathbf{i}}$$

We see that the Poynting vector points in the negative <u>*x*</u> direction, and so the wave moves in the negative *x* direction, which is perpendicular to both $\vec{\mathbf{E}}$ and $\vec{\mathbf{B}}$.

(*c*) We find the magnitude of the electric field vector and the magnetic field vector.



$$\left|\vec{\mathbf{E}}\right| = E = \left(\left[E_0 \sin(kx - \omega t)\right]^2 + \left[E_0 \cos(kx - \omega t)\right]^2\right)^{1/2}$$

$$= \left[E_0^2 \sin^2(kx - \omega t) + E_0^2 \cos^2(kx - \omega t)\right]^{1/2} = E_0$$

$$\left|\vec{\mathbf{B}}\right| = B = \left(\left[B_0 \cos(kx - \omega t)\right]^2 + \left[B_0 \sin(kx - \omega t)\right]^2\right)^{1/2}$$

$$= \left[B_0^2 \cos^2(kx - \omega t) + B_0^2 \sin^2(kx - \omega t)\right]^{1/2} = B_0$$

(*d*) At $x = 0$ and $t = 0$, $\vec{\mathbf{E}} = E_0\hat{\mathbf{k}}$ and $\vec{\mathbf{B}} = B_0\hat{\mathbf{j}}$. See the figure. The *x* axis is coming out of the page toward the reader. As time increases, the component of the electric field in the *z* direction electric field begins to get smaller and the component in the negative *y* direction begins to get larger. At the same time, the component of the magnetic field in the *y* direction begins to get smaller, and the component in the *z* direction begins to get larger. The net effect is that <u>both vectors rotate counterclockwise</u>.

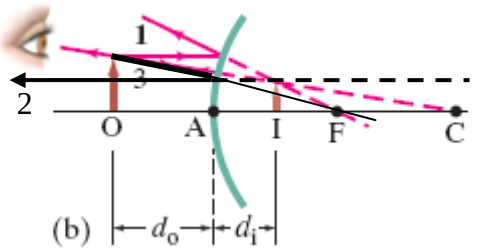
CHAPTER 32: Light: Reflection and Refraction

Responses to Questions



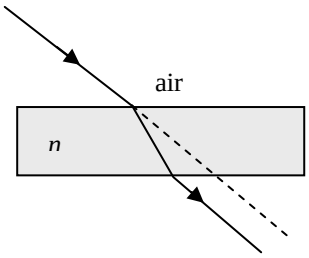
1. (*a*) The Moon would look just like it does now, since the surface is rough. Reflected sunlight is scattered by the surface of the Moon in many directions, making the surface appear white.
(*b*) With a polished, mirror-like surface, the Moon would reflect an image of the Sun, the stars, and the Earth. The appearance of the Moon would be different as seen from different locations on the Earth.

2. Yes, it would have been possible, although certainly difficult. Several attempts have been made to reenact the event in order to test its feasibility. Two of the successful attempts include a 1975 experiment directed by Greek scientist Dr. Ioannis Sakkas and a 2005 experiment performed by a group of engineering students at MIT. (See www.mit.edu for links to both these and other similar experiments.) In both these cases, several individual mirrors operating together simulated a large spherical mirror and were used to ignite a wooden boat. If in fact the story is true, Archimedes would have needed good weather and an enemy fleet that cooperated by staying relatively still while the focused sunlight heated the wood.

3. The focal length of a plane mirror is infinite. The magnification of a plane mirror is 1.

4. The image is real and inverted, because the magnification is negative. The mirror is concave, because convex mirrors can only form virtual images. The image is on the same side of the mirror as the object; real images are formed by converging light rays and light rays cannot actually pass through a mirror.

5. Ray 2 is directed as if it were going through the focal point and is reflected from the convex mirror parallel to the principal axis.



6. Yes. For a plane mirror, $d_o = -d_i$, since the object and image are equidistant from the mirror and the image is virtual, or behind the mirror. The focal length of a plane mirror is infinite, so the result of the mirror equation, Eq. 32-2, is $\frac{1}{d_o} + \frac{1}{d_i} = 0$, or $d_o = -d_i$, as expected.

7. Yes. When a concave mirror produces a real image of a real object, both d_o and d_i are positive. The magnification equation, $m = -\frac{d_i}{d_o}$, results in a negative magnification, which indicates that the image is inverted.

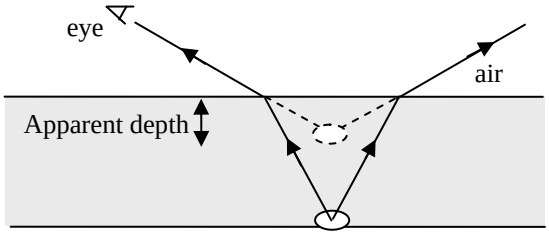
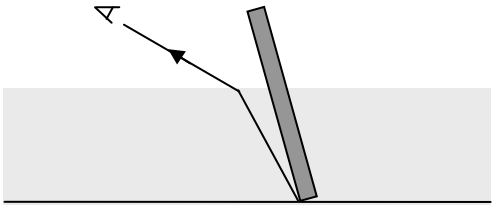
8. A light ray entering the solid rectangular object will exit the other side following a path that is parallel to its original path but displaced slightly from it. The angle of refraction in the glass can be determined geometrically from this displacement and the thickness of the object. The index of refraction can then be determined using Snell's Law with this angle of refraction and the original angle of incidence. The speed of light in the material follows from the definition of the index of refraction: $n = c/v$.

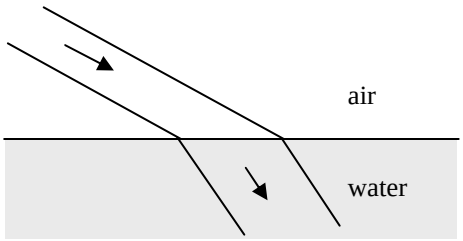


9. This effect is similar to diffuse reflection off of a rough surface. A ripply sea has multiple surfaces which are at an angle to reflect the image of the Moon into your eyes. This makes the image of the Moon appear elongated.

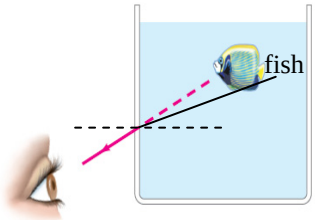


10. A negative object distance corresponds to a virtual object. This could occur if converging rays from another mirror or lens were intercepted by the mirror before actually forming an image. This image would be the object for the mirror.

11. The angle of refraction and the angle of incidence are both zero in this case.



12. Underestimate. The light rays leaving the bottom of the pool bend away from the normal as they enter the air, so their source appears to be more shallow than it actually is. The greater the viewing angle, the more the bending of the light and therefore the less the apparent depth.



13. Your brain interprets the refracted rays as if the part of the stick that is under water is closer to the surface than it actually is, so the stick appears bent.

14. Because the broad beam hits the surface of the water at an angle, it illuminates an area of the surface that is wider than the beam width. Light from the beam bends towards the normal. The refracted beam is wider than the incident beam because one edge of the beam strikes the surface first, while the other edge travels farther in the air. (See the adjacent diagram.)

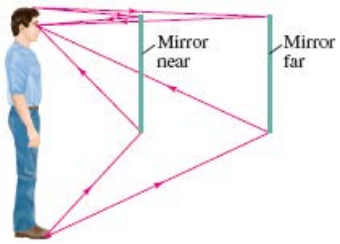
15. The light rays from the fish are bent away from the normal as they leave the tank. The fish will appear closer to the side of the tank than it really is.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16. The water drop acts like a lens, and refracts light as the light passes through it. Also, some of the light incident on the air/water boundary is reflected at the surface, so the drop can be seen in reflected light.

17. When the light ray passes from the blue material to the green material, the ray bends toward the normal. This indicates that the index of refraction of the blue material is less than that of the green material. When the light ray passes from the green material to the yellow material, the ray bends away from the normal, but not far enough to make the ray parallel to the initial ray, indicating that the index of refraction of the yellow material is less than that of the green material but larger than the index of refraction of the blue material. The ranking of the indices of refraction is, least to greatest, blue, yellow, and green.

18. No. Total internal reflection can only occur when light travels from a medium of higher index of refraction to a medium of lower index of refraction.

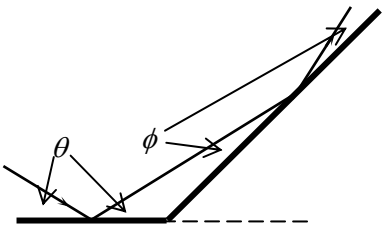


19. No. The refraction of light as it enters the pool will make the object look smaller. See Figure 32-32 and Conceptual Example 32-11.

20. The mirror is concave, and the person is standing inside the focal point so that a virtual, upright image is formed. (A convex mirror would also form a virtual, upright image but the image would be smaller than the object.) In addition, an image is also present at the far right edge of the mirror, which is only possible if the mirror is concave.

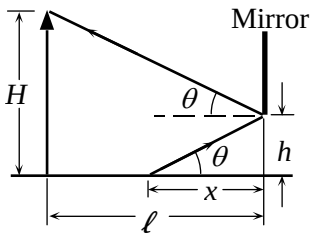
21. (*a*) Since the light is coming from a vacuum into the atmosphere, which has a larger index of refraction, the light rays should bend toward the normal (toward the vertical direction).
(*b*) The stars are closer to the horizon than they appear to be from the surface of the Earth.

Solutions to Problems



1. Because the angle of incidence must equal the angle of reflection, we see from the ray diagrams that the ray that reflects to your eye must be as far below the horizontal line to the reflection point on the mirror as the top is above the line, regardless of your position.

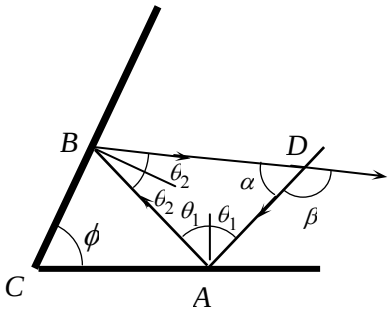
2. For a flat mirror the image is as far behind the mirror as the object is in front, so the distance from object to image is twice the distance from the object to the mirror, or $\boxed{5.6\,\text{m}}$.



3. The law of reflection can be applied twice. At the first reflection, the angle is θ, and at the second reflection, the angle is ϕ.
Consider the triangle formed by the mirrors and the first reflected ray.

$$\theta + \alpha + \phi = 180^\circ \;\rightarrow\; 38^\circ + 135^\circ + \phi = 180^\circ \;\rightarrow\; \boxed{\phi = 7^\circ}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



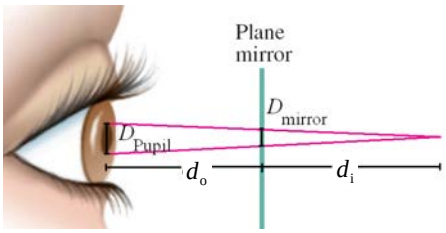
4. The angle of incidence is the angle of reflection. See the diagram for the appropriate lengths.

$$\tan\theta = \frac{(H-h)}{\ell} = \frac{h}{x} \rightarrow$$

$$\frac{(1.64\,\text{m} - 0.38\,\text{m})}{(2.30\,\text{m})} = \frac{(0.38\,\text{m})}{x} \rightarrow x = \boxed{0.69\,\text{m}}$$

5. The incoming ray is represented by line segment DA. For the first reflection at *A* the angles of incidence and reflection are θ_1. For the second reflection at *B* the angles of incidence and reflection are θ_2. We relate θ_1 and θ_2 to the angle at which the mirrors meet, ϕ, by using the sum of the angles of the triangle *ABC*.

$$\phi + (90° - \theta_1) + (90° - \theta_2) = 180° \rightarrow \phi = \theta_1 + \theta_2$$



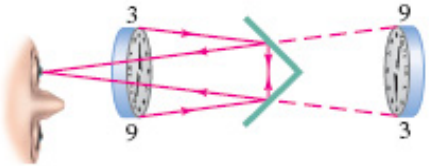
Do the same for triangle *ABD*.

$$\alpha + 2\theta_1 + 2\theta_2 = 180° \rightarrow \alpha = 180° - 2(\theta_1 + \theta_2) = 180° - 2\phi$$

At point *D* we see that the deflection is as follows.

$$\beta = 180° - \alpha = 180° - (180° - 2\phi) = \boxed{2\phi}$$

6. The rays entering your eye are diverging from the virtual image position behind the mirror. Thus the diameter of the area on the mirror and the diameter of your pupil must subtend the same angle from the image.



$$\frac{D_{\text{mirror}}}{d_i} = \frac{D_{\text{pupil}}}{(d_o + d_i)} \rightarrow D_{\text{mirror}} = D_{\text{pupil}} \frac{d_i}{(d_o + d_i)} = \tfrac{1}{2} D_{\text{pupil}}$$

$$A_{\text{mirror}} = \tfrac{1}{4}\pi D_{\text{mirror}}^2 = \tfrac{1}{4}\pi \tfrac{1}{4} D_{\text{pupil}}^2 = \frac{\pi}{16}\left(4.5\times10^{-3}\,\text{m}\right)^2$$

$$= \boxed{4.0\times10^{-6}\,\text{m}^2}$$

7. See the "top view" ray diagram.

8. (*a*) The velocity of the incoming light wave is in the direction of the initial light wave. We can write this velocity in component form, where the three axes of our coordinate system are chosen to be perpendicular to the plane of each of the three mirrors. As the light reflects off any of the three mirrors, the component of the velocity perpendicular to that mirror reverses direction. The other two velocity components will remain unchanged. After the light has reflected off of each of the three mirrors, each of the three velocity components will be reversed and the light will be traveling directly back from where it came.

(*b*) If the mirrors are assumed to be large enough, the light can only reflect off two of the mirrors if the velocity component perpendicular to the third mirror is zero. Therefore, in this case the light is still reflected back directly to where it came.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9. The rays from the Sun will be parallel, so the image will be at the focal point, which is half the radius of curvature.

$$r = 2f = 2(18.8\text{cm}) = \boxed{37.6\text{cm}}$$

10. To produce an image at infinity, the object must be at the focal point, which is half the radius of curvature.

$$d_\text{o} = f = \tfrac{1}{2}r = \tfrac{1}{2}(24.0\text{cm}) = \boxed{12.0\text{cm}}$$

11. The image flips at the focal point, which is half the radius of curvature. Thus the radius is $\boxed{1.0\text{ m}}$.

12. (*a*) The focal length is half the radius of curvature, so $f = \tfrac{1}{2}r = \tfrac{1}{2}(24\text{cm}) = \boxed{12\text{cm}}$.

(*b*) Use Eq. 32-2.

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad d_\text{i} = \frac{d_\text{o} f}{d_\text{o} - f} = \frac{(35\text{cm})(24\text{cm})}{35\text{cm} - 24\text{cm}} = \boxed{76\text{cm}}$$

(*c*) The image is $\boxed{\text{inverted}}$, since the magnification is negative.

13. The ball is a convex mirror with a focal length $f = \tfrac{1}{2}r = \tfrac{1}{2}(-4.6\text{cm}) = -2.3\text{cm}$. Use Eq. 32-3 to locate the image.

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad d_\text{i} = \frac{d_\text{o} f}{d_\text{o} - f} = \frac{(25.0\text{cm})(-2.3\text{cm})}{25.0\text{cm} - (-2.3\text{cm})} = -2.106\text{cm} \approx -2.1\text{cm}$$

The image is $\boxed{\text{2.1 cm behind the surface of the ball, virtual, and upright}}$. Note that the magnification is $m = -\dfrac{d_\text{i}}{d_\text{o}} = \dfrac{-(-2.106\text{cm})}{(25.0\text{cm})} = +0.084$.

14. The image distance can be found from the object distance of 1.7 m and the magnification of +3. With the image distance and object distance, the focal length and radius of curvature can be found.

$$m = \frac{-d_\text{i}}{d_\text{o}} \quad \rightarrow \quad d_\text{i} = -md_\text{o}$$

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = \frac{d_\text{o} d_\text{i}}{d_\text{o} + d_\text{i}} = \frac{d_\text{o}(-md_\text{o})}{d_\text{o} - md_\text{o}} = \frac{md_\text{o}}{m-1} = \frac{3(1.7\text{m})}{3-1} = 2.55\text{m}$$

$$r = 2f = 2(2.55\text{m}) = \boxed{5.1\text{m}}$$

15. The object distance of 2.00 cm and the magnification of +4.0 are used to find the image distance. The focal length and radius of curvature can then be found.

$$m = \frac{-d_\text{i}}{d_\text{o}} \quad \rightarrow \quad d_\text{i} = -md_\text{o}$$

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = \frac{d_\text{o} d_\text{i}}{d_\text{o} + d_\text{i}} = \frac{d_\text{o}(-md_\text{o})}{d_\text{o} - md_\text{o}} = \frac{md_\text{o}}{m-1} = \frac{4(2.00\text{cm})}{4-1} = 2.677\text{cm}$$

$$r = 2f = 2(2.667\text{cm}) = \boxed{5.3\text{cm}}$$

Because the focal length is positive, the mirror is $\boxed{\text{concave}}$.

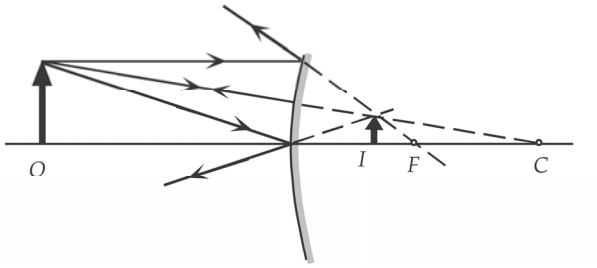
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16. The mirror must be convex. Only convex mirrors produce images that are upright and smaller than the object. The object distance of 18.0 m and the magnification of +0.33 are used to find the image distance. The focal length and radius of curvature can then be found.

$$m = \frac{-d_\text{i}}{d_\text{o}} \quad \rightarrow \quad d_\text{i} = -md_\text{o}$$

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = \frac{d_\text{o}d_\text{i}}{d_\text{o}+d_\text{i}} = \frac{d_\text{o}\left(-md_\text{o}\right)}{d_\text{o}-md_\text{o}} = \frac{md_\text{o}}{m-1} = \frac{0.33(18.0\,\text{m})}{0.33-1} = -8.866\,\text{m}$$

$$r = 2f = 2(-8.866\,\text{m}) = \boxed{-17.7\,\text{m}}$$



17. The object distance of 3.0 m and the magnification of +0.5 are used to find the image distance. The focal length and radius of curvature can then be found.

$$m = \frac{-d_\text{i}}{d_\text{o}} \quad \rightarrow \quad d_\text{i} = -md_\text{o}$$

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = \frac{d_\text{o}d_\text{i}}{d_\text{o}+d_\text{i}} = \frac{d_\text{o}\left(-md_\text{o}\right)}{d_\text{o}-md_\text{o}} = \frac{md_\text{o}}{m-1} = \frac{0.5(3.0\,\text{m})}{0.5-1} = -3.0\,\text{m}$$

$$r = 2f = 2(-3.0\,\text{m}) = \boxed{-6.0\,\text{m}}$$

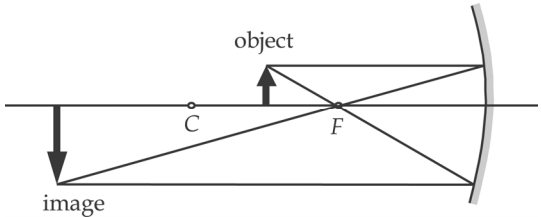
18. (*a*) From the ray diagram it is seen that the image is virtual. We estimate the image distance as $\boxed{-6\,\text{cm.}}$

(*b*) Use a focal length of $-9.0\,\text{cm}$ with the object distance of $18.0\,\text{cm}$.

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow$$

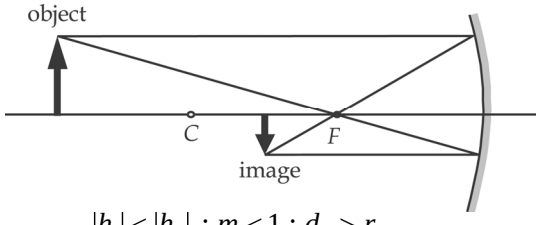
$$d_\text{i} = \frac{d_\text{o}f}{d_\text{o}-f} = \frac{(18.0\,\text{cm})(-9.0\,\text{cm})}{18.0\,\text{cm}-(-9.0\,\text{cm})} = \boxed{-6.0\,\text{cm}}$$

(*c*) We find the image size from the magnification:



$$m = \frac{h_\text{i}}{h_\text{o}} = \frac{-d_\text{i}}{d_\text{o}} \quad \rightarrow \quad h_\text{i} = h_\text{o}\left(\frac{-d_\text{i}}{d_\text{o}}\right) = (3.0\,\text{mm})\left(\frac{6.0\,\text{cm}}{18.0\,\text{cm}}\right) = \boxed{1.0\,\text{mm}}$$

19. Take the object distance to be ∞, and use Eq. 32-3. Note that the image distance is negative since the image is behind the mirror.



$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad \frac{1}{\infty} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = d_\text{i} = -16.0\,\text{cm} \quad \rightarrow \quad r = 2f = \boxed{-32.0\,\text{cm}}$$

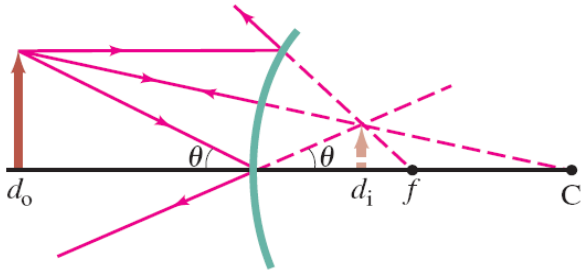
Because the focal length is negative, the mirror is convex.

20. (*a*)

$|h_\text{i}| > |h_\text{o}|$; $m > 1$; $d_\text{o} < r$

$|h_\text{i}| < |h_\text{o}|$; $m < 1$; $d_\text{o} > r$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

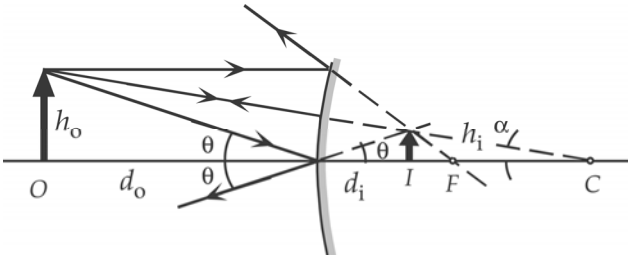


(*b*) Apply Eq. 32-3 and Eq. 32-4.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}=\frac{2}{r} \quad \rightarrow \quad d_i=\frac{rd_o}{(2d_o-r)} \quad ; \quad m=\frac{-d_i}{d_o}=\frac{-r}{(2d_o-r)}$$

If $d_o > r$, then $(2d_o - r) > r$, so $|m|=\dfrac{r}{(2d_o-r)}=\dfrac{r}{(>r)}<1.$

If $d_o < r$, then $(2d_o - r) < r$, so $|m|=\dfrac{r}{(2d_o-r)}=\dfrac{r}{(<r)}>1.$



21. Consider the ray that reflects from the center of the mirror, and note that $d_i < 0$.

$$\tan\theta=\frac{h_o}{d_o}=\frac{h_i}{-d_i} \quad \rightarrow \quad \frac{-d_i}{d_o}=\frac{h_i}{h_o}$$

$$m=\frac{h_i}{h_o}=\boxed{-\frac{d_i}{d_o}}$$

22. From the ray diagram, we see that with a negative image distance, we have the following.

$$\tan\theta=\frac{h_o}{d_o}=\frac{h_i}{-d_i}$$

$$\tan\alpha=\frac{h_o}{(d_o+r)}=\frac{h_i}{(r+d_i)}$$

When we divide the two equations, we get

$$\frac{(d_o+r)}{d_o}=-\frac{(r+d_i)}{d_i} \quad \rightarrow \quad 1+\frac{r}{d_o}=-1-\frac{r}{d_i} \quad \rightarrow \quad \frac{r}{d_o}+\frac{r}{d_i}=-2 \quad \rightarrow \quad \frac{1}{d_o}+\frac{1}{d_i}=-\frac{2}{r}$$

If we define $f=\dfrac{r}{2}$ and consider the radius of curvature and focal length to be negative, then we have Eq. 32-2, $\boxed{\dfrac{1}{d_o}+\dfrac{1}{d_i}=\dfrac{1}{f}}$..

23. Use Eq. 32-2 and 32-3.

$$m=\frac{-d_i}{d_o} \quad \rightarrow \quad d_i=-md_o$$

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad f=\frac{d_o d_i}{d_o+d_i}=\frac{d_o(-md_o)}{d_o-md_o}=\frac{md_o}{m-1}=\frac{(0.55)(3.2\,\text{m})}{0.55-1}=\boxed{-3.9\,\text{m}}$$

24. (*a*) We are given that $d_i = d_o$. Use Eq. 32-3.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad \frac{2}{d_o}=\frac{1}{f} \quad \rightarrow \quad \boxed{d_o=2f=r}$$

The object should be placed at the center of curvature.

(*b*) Because the image is in front of the mirror, $d_i > 0$, it is real.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) The magnification is $m = \dfrac{-d_\text{i}}{d_\text{o}} = \dfrac{-d_\text{o}}{d_\text{o}} = -1$. Because the magnification is negative, the image is **inverted.**

(*d*) As found in part (*c*), $m =$ **-1.**

25. (*a*) To produce a smaller image located behind the surface of the mirror requires a **convex mirror.**

(*b*) Find the image distance from the magnification.

$$m = \frac{h_\text{i}}{h_\text{o}} = \frac{-d_\text{i}}{d_\text{o}} \quad \rightarrow \quad d_\text{i} = -\frac{d_\text{o} h_\text{i}}{h_\text{o}} = -\frac{(26\,\text{cm})(3.5\,\text{cm})}{(4.5\,\text{cm})} = -20.2\,\text{cm} \approx \boxed{-20\,\text{cm}} \text{ (2 sig. fig.)}$$

As expected, $d_\text{i} < 0$. The image is located **20 cm behind the surface.**

(*c*) Find the focal length from Eq. 32.3.

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = \frac{d_\text{o} d_\text{i}}{d_\text{o} + d_\text{i}} = \frac{(26\,\text{cm})(-20.2\,\text{cm})}{(26\,\text{cm}) + (-20.2\,\text{cm})} = -90.55\,\text{cm} \approx \boxed{-91\,\text{cm}}$$

(*d*) The radius of curvature is twice the focal length.

$$r = 2f = 2(-90.55\,\text{cm}) = -181.1\,\text{cm} \approx \boxed{-180\,\text{cm}}$$

26. (*a*) To produce a larger upright image requires a **concave mirror.**

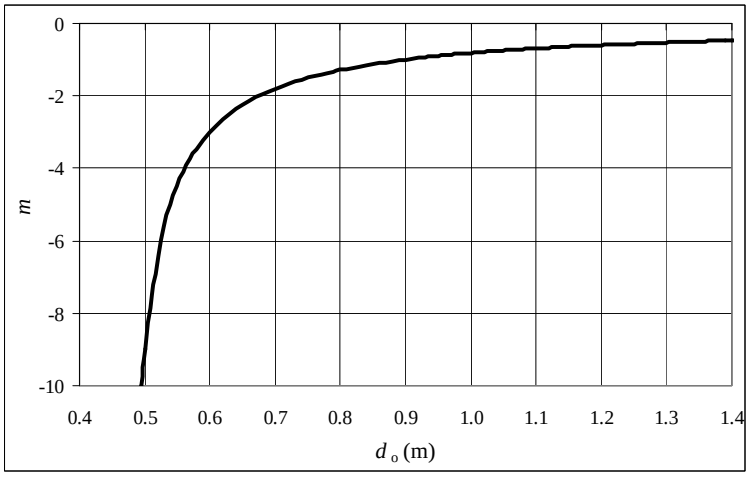
(*b*) The image will be **upright and virtual.**

(*c*) We find the image distance from the magnification:

$$m = \frac{h_\text{i}}{h_\text{o}} = \frac{-d_\text{i}}{d_\text{o}} \quad \rightarrow \quad d_\text{i} = -m d_\text{o}$$

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = \frac{d_\text{o} d_\text{i}}{d_\text{o} + d_\text{i}} = \frac{d_\text{o}(-m d_\text{o})}{d_\text{o} - m d_\text{o}} = \frac{m d_\text{o}}{m - 1} \quad \rightarrow$$

$$r = 2f = \frac{2 m d_\text{o}}{m - 1} = \frac{2(1.35)(20.0\,\text{cm})}{1.35 - 1} = \boxed{154\,\text{cm}}$$



27. (*a*) We use the magnification equation, Eq. 32-3, to write the image distance in terms of the magnification and object distance. We then replace the image distance in the mirror equation, Eq. 32-2, and solve for the magnification in terms of the object distance and the focal length.

$$m = -d_\text{i}/d_\text{o} \quad \rightarrow \quad d_\text{i} = -m d_\text{o}$$

$$\frac{1}{f} = \frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} \quad \rightarrow$$

$$\frac{1}{f} = \frac{1}{d_\text{o}} + \frac{1}{-m d_\text{o}} \quad \rightarrow$$

$$\boxed{m = \frac{f}{f - d_\text{o}}}$$

(*b*) We set $f = 0.45$ m and draw a graph of the magnification as a function of the object distance. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH32.XLS," on tab "Problem 32.27b."

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) The image and object will have the same lateral size when the magnification is equal to negative one. Setting the magnification equal to negative one, we solve the equation found in part (a) for the object distance.

$$m = \frac{f}{f - d_o} = -1 \quad \rightarrow \quad d_o = 2f = \boxed{0.90\,\text{m}}$$

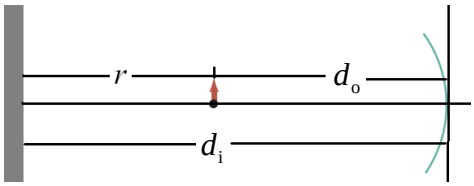
(*d*) From the graph we see that for the image to be much larger than the object, the object should be placed at a point **just beyond the focal point.**

28. We use the magnification equation, Eq. 32-3, to write the image distance in terms of the magnification and object distance. We then replace the image distance in the mirror equation, Eq. 32-2, and solve for the magnification in terms of the object distance and the focal length, with the focal length given as $f = -|f|$.

$$m = -\frac{d_i}{d_o} \quad \rightarrow \quad d_i = -md_o \quad \rightarrow \quad \frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} \rightarrow \frac{1}{-|f|} = \frac{1}{d_o} + \frac{1}{-md_o} \rightarrow \boxed{m = \frac{|f|}{|f| + d_o}}$$

From this relation, the closer the object is to the mirror (i.e., smaller object distance) the greater the magnification. Since a person's nose is closer to the mirror than the rest of the face, its image appears larger.

29. (*a*) We use the magnification equation, Eq. 32-3, to write the image distance in terms of the magnification and object distance. We then replace the image distance in the mirror equation, Eq. 32-2, and solve for the object distance in terms of the magnification and the focal length.



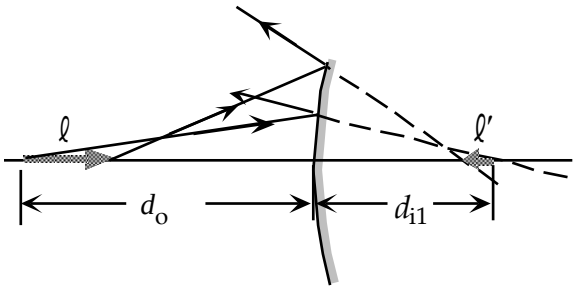
$$m = -\frac{d_i}{d_o} \rightarrow d_i = -md_o$$

$$\frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} \rightarrow \frac{1}{f} = \frac{1}{d_o} + \frac{1}{-md_o} = \frac{1}{d_o}\left(1 - \frac{1}{m}\right) \rightarrow \boxed{d_o = f\left(1 - \frac{1}{m}\right)}$$

(*b*) We set the object distance equal to the range of all positive numbers. Since the focal length of a convex lens is negative, the term in parentheses in the above equation must be the range of all negative numbers for the object distance to include the range of all positive numbers. We solve the resulting equation for all possible values of the magnification.

$$\left(1 - \frac{1}{m}\right) \le 0 \rightarrow 1 \le \frac{1}{m} \rightarrow \boxed{0 \le m \le 1}$$

30. The distance between the mirror and the wall is equal to the image distance, which we can calculate using Eq. 32-2. The object is located a distance *r* from the wall, so the object distance will be *r* less than the image distance. The focal length is given by Eq. 32-1. For the object distance to be real, the image distance must be greater than *r*.



$$\frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} \rightarrow \frac{2}{r} = \frac{1}{d_i - r} + \frac{1}{d_i} \rightarrow 2d_i^2 - 4d_i r + r^2 = 0$$

$$d_i = \frac{4r \pm \sqrt{16r^2 - 8r^2}}{4} = r\left(1 \pm \frac{\sqrt{2}}{2}\right) \approx 0.292r \text{ or } \boxed{1.71r}$$

Use Eq. 32-3 to calculate the magnification: $m = -\frac{d_i}{d_o} = \frac{1.71r}{1.71r - r} = \boxed{-2.41}$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31. The lateral magnification of an image equals the height of the image divided by the height of the object. This can be written in terms of the image distance and focal length with Eqs. 32-2 and 32-3.

$$\frac{1}{f}=\frac{1}{d_i}+\frac{1}{d_o} \quad \rightarrow \quad d_i=\left(\frac{fd_o}{d_o-f}\right)$$

$$m=\frac{-d_i}{d_o}=-\frac{f}{d_o-f}$$

The longitudinal magnification will be the difference in image distances of the two ends of the object divided by the length of the image. Call the far tip of the wire object 1 with object distance d_o. The close end of the wire will be object 2 with object distance $d_o-\ell$. Using Eq. 32-2 we can find the image distances for both ends.

$$\frac{1}{f}=\frac{1}{d_o}+\frac{1}{d_{i1}} \quad \rightarrow \quad d_{i1}=\frac{d_o f}{d_o-f} \;\; ; \;\; \frac{1}{f}=\frac{1}{d_o-\ell}+\frac{1}{d_{i2}} \quad \rightarrow \quad d_{i2}=\frac{(d_o-\ell)f}{d_o-\ell-f}$$

Taking the difference in image distances and dividing by the object length gives the longitudinal magnification.

$$m_\ell=\frac{d_{i1}-d_{i2}}{\ell}=\frac{1}{\ell}\left(\frac{d_o f}{d_o-f}-\frac{(d_o-\ell)f}{d_o-\ell-f}\right)=\frac{d_o f(d_o-\ell-f)-(d_o-f)(d_o-\ell)f}{\ell(d_o-f)(d_o-\ell-f)}$$

$$=\frac{-f^2}{(d_o-f)(d_o-\ell-f)}$$

Set $\ell \ll d_o$, so that the ℓ drops out of the second factor of the denominator. Then rewrite the equation in terms of the lateral magnification, using the expression derived at the beginning of the problem.

$$m_\ell=\frac{-f^2}{(d_o-f)^2}=-\left[\frac{f}{(d_o-f)}\right]^2=\boxed{-m^2}$$

The negative sign indicates that the image is reversed front to back, as shown in the diagram.

32. We find the index of refraction from Eq. 32-1.

$$n=\frac{c}{v}=\frac{3.00\times10^8\ \text{m/s}}{2.29\times10^8\ \text{m/s}}=\boxed{1.31}$$

33. In each case, the speed is found from Eq. 32-1 and the index of refraction.

(*a*) Ethyl alcohol: $v=\dfrac{c}{n}=\dfrac{3.00\times10^8\ \text{m/s}}{1.36}=\boxed{2.21\times10^8\ \text{m/s}}$

(*b*) Lucite: $v=\dfrac{c}{n}=\dfrac{3.00\times10^8\ \text{m/s}}{1.51}=\boxed{1.99\times10^8\ \text{m/s}}$

(*c*) Crown glass: $v=\dfrac{c}{n}=\dfrac{3.00\times10^8\ \text{m/s}}{1.52}=\boxed{1.97\times10^8\ \text{m/s}}$

34. Find the distance traveled by light in 4.2 years.

$$d=c\Delta t=\left(3.00\times10^8\ \text{m/s}\right)\left(4.2\ \text{yr}\right)\left(3.16\times10^7\ \text{s/yr}\right)=\boxed{4.0\times10^{16}\ \text{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

35. The time for light to travel from the Sun to the Earth is found from the distance between them and the speed of light.

$$\Delta t = \frac{d}{c} = \frac{1.50\times10^{11}\,\text{m}}{3.00\times10^{8}\,\text{m/s}} = 5.00\times10^{2}\,\text{s} = \boxed{8.33\,\text{min}}$$

36. We find the index of refraction from Eq. 32-1.

$$n = \frac{c}{v} = \frac{c}{0.88v_{\text{water}}} = \frac{c}{0.88\left(\dfrac{c}{n_{\text{water}}}\right)} = \frac{n_{\text{water}}}{0.88} = \frac{1.33}{0.88} = \boxed{1.51}$$

37. The length in space of a burst is the speed of light times the elapsed time.

$$d = ct = \left(3.00\times10^{8}\,\text{m/s}\right)\left(10^{-8}\text{s}\right) = \boxed{3\text{m}}$$

38. Find the angle of refraction from Snell's law.

$$n_1\sin\theta_1 = n_2\sin\theta_2 \quad\rightarrow\quad \theta_2 = \sin^{-1}\left(\frac{n_1}{n_2}\sin\theta_1\right) = \sin^{-1}\left(\frac{1.33}{1.00}\sin 38.5°\right) = \boxed{55.9°}$$

39. Find the angle of refraction from Snell's law.

$$n_1\sin\theta_1 = n_2\sin\theta_2 \quad\rightarrow\quad \theta_2 = \sin^{-1}\left(\frac{n_1}{n_2}\sin\theta_1\right) = \sin^{-1}\left(\frac{1.00}{1.56}\sin 63°\right) = \boxed{35°}$$

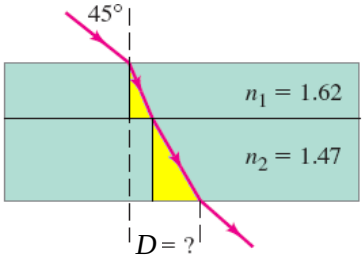
40. We find the incident angle in the air (relative to the normal) from Snell's law.

$$n_1\sin\theta_1 = n_2\sin\theta_2 \quad\rightarrow\quad \theta_1 = \sin^{-1}\left(\frac{n_2}{n_1}\sin\theta_2\right) = \sin^{-1}\left(\frac{1.33}{1.00}\sin 33.0°\right) = 46.4°$$

Since this is the angle relative to the horizontal, the angle as measured from the horizon is $90.0° - 46.4° = \boxed{43.6°}$.

41. We find the incident angle in the water from Snell's law.

$$n_1\sin\theta_1 = n_2\sin\theta_2 \quad\rightarrow\quad \theta_1 = \sin^{-1}\left(\frac{n_2}{n_1}\sin\theta_2\right) = \sin^{-1}\left(\frac{1.00}{1.33}\sin 56.0°\right) = \boxed{38.6°}$$



42. The angle of reflection is equal to the angle of incidence: $\theta_{\text{ref1}} = \theta_1 = 2\theta_2$. Use Snell's law

$$n_{\text{air}}\sin\theta_1 = n_{\text{glass}}\sin\theta_2 \quad\rightarrow\quad (1.00)\sin 2\theta_2 = (1.56)\sin\theta_2$$

$$\sin 2\theta_2 = 2\sin\theta_2\cos\theta_2 = (1.56)\sin\theta_2 \quad\rightarrow\quad \cos\theta_2 = 0.780 \quad\rightarrow\quad \theta_2 = 38.74°$$

$$\theta_1 = 2\theta_2 = \boxed{77.5°}$$

43. The beam forms the hypotenuse of two right triangles as it passes through the plastic and then the glass. The upper angle of the triangle is the angle of refraction in that medium. Note that the sum of the opposite sides is equal to the displacement *D*. First, we calculate the angles of refraction in each medium using Snell's Law (Eq. 32-5).

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\sin 45 = n_1 \sin\theta_1 = n_2 \sin\theta_2$$

$$\theta_1 = \sin^{-1}\left(\frac{\sin 45}{n_1}\right) = \sin^{-1}\left(\frac{\sin 45}{1.62}\right) = 25.88°$$

$$\theta_2 = \sin^{-1}\left(\frac{\sin 45}{n_2}\right) = \sin^{-1}\left(\frac{\sin 45}{1.47}\right) = 28.75°$$

We then use the trigonometric identity for tangent to calculate the two opposite sides, and sum to get the displacement.

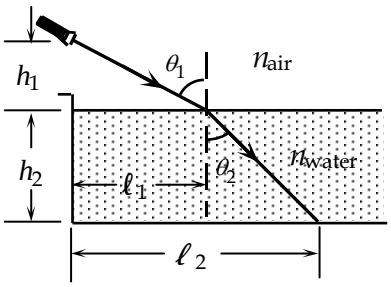
$$D = D_1 + D_2 = h_1 \tan\theta_1 + h_1 \tan\theta_1 = (2.0\,\text{cm})\tan 25.88° + (3.0\,\text{cm})\tan 28.75° = \boxed{2.6\,\text{cm}}$$

44. (*a*) We use Eq. 32-5 to calculate the refracted angle as the light enters the glass (n=1.56) from the air (n=1.00).

$$n_1 \sin\theta_1 = n_2 \sin\theta_2 \rightarrow \theta_2 = \sin^{-1}\left[\frac{n_1}{n_2}\sin\theta_1\right] = \sin^{-1}\left[\frac{1.00}{1.56}\sin\ 43.5°\right] = 26.18° \approx \boxed{26.2°}$$

(*b*) We again use Eq. 32-5 using the refracted angle in the glass and the indices of refraction of the glass and water.

$$\theta_3 = \sin^{-1}\left[\frac{n_2}{n_3}\sin\theta_2\right] = \sin^{-1}\left[\frac{1.56}{1.33}\sin\ 26.18°\right] = 31.17° \approx \boxed{31.2°}$$



(*c*) We repeat the same calculation as in part (a), but using the index of refraction of water.

$$\theta_3 = \sin^{-1}\left[\frac{n_1}{n_3}\sin\theta_1\right] = \sin^{-1}\left[\frac{1.00}{1.33}\sin\ 43.5°\right] = 31.17° \approx \boxed{31.2°}$$

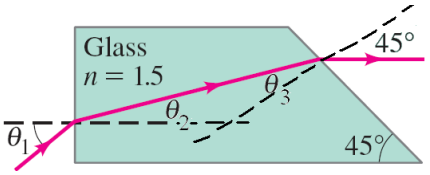
As expected the refracted angle in the water is the same whether the light beam first passes through the glass, or passes directly into the water.

45. We find the angle of incidence from the distances.

$$\tan\theta_1 = \frac{\ell_1}{h_1} = \frac{(2.5\,\text{m})}{(1.3\,\text{m})} = 1.9231 \quad \rightarrow \quad \theta_1 = 62.526°$$

For the refraction from air into water, we have

$$n_{\text{air}} \sin\theta_1 = n_{\text{water}} \sin\theta_2;$$



$$(1.00)\sin 62.526° = (1.33)\sin\theta_2 \quad \rightarrow \quad \theta_2 = 41.842°$$

We find the horizontal distance from the edge of the pool from

$$\ell = \ell_1 + \ell_2 = \ell_1 + h_2 \tan\theta_2$$

$$= 2.5\,\text{m} + (2.1\,\text{m})\tan 41.842° = 4.38\,\text{m} \approx \boxed{4.4\,\text{m}}$$

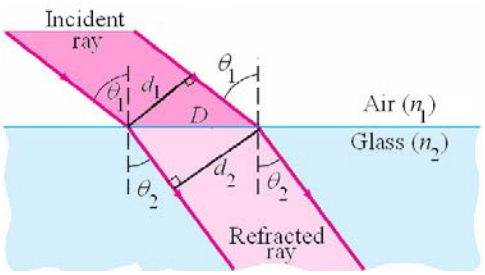
46. Since the light ray travels parallel to the base when it exits the glass, and the back edge of the glass makes a 45° angle to the horizontal, the exiting angle of refraction is 45°. We use Snell's law, Eq. 32-5, to calculate the incident angle at the back pane.

$$\theta_3 = \sin^{-1}\left[\frac{n_4}{n_3}\sin\theta_4\right] = \sin^{-1}\left[\frac{1.0}{1.5}\sin\ 45°\right] = 28.13°$$

We calculate the refracted angle at the front edge of the glass by noting that the angles θ_2 and θ_3 in the figure form two angles of a triangle. The third angle, as determined by the perpendiculars to the surface, is 135°.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\theta_2 + \theta_3 + 135° = 180° \rightarrow \theta_2 = 45° - \theta_3 = 45° - 28.13° = 16.87°$



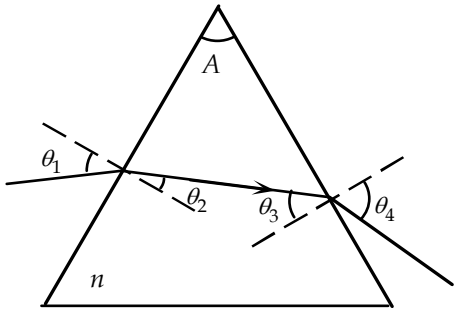
Finally, we use Snell's law at the front face of the glass to calculate the incident angle.

$$\theta_1 = \sin^{-1}\left[\frac{n_2}{n_1}\sin\theta_2\right] = \sin^{-1}\left[\frac{1.5}{1.0}\sin\ 16.87°\right] = 25.81° \approx \boxed{26°}$$

47. As the light ray passes from air into glass with an angle of incidence of 25°, the beam will refract. Determine the angle of refraction by applying Snell's law.

$n_1 \sin\theta_1 = n_2 \sin\theta_2 \rightarrow$

$$\theta_2 = \sin^{-1}\left[\frac{n_1}{n_2}\sin\theta_1\right] = \sin^{-1}\left[\frac{1.00}{1.5}\sin\ 25°\right] = 16.36°$$



We now consider the two right triangles created by the diameters of the incident and refracted beams with the air–glass interface, as shown in the figure. The diameters form right angles with the ray direction and using complementary angles we see that the angle between the diameter and the interface is equal to the incident and refracted angles. Since the air–glass interface creates the hypotenuse for both triangles we use the definition of the cosine to solve for this length in each triangle and set the lengths equal. The resulting equation is solved for the diameter of the refracted ray.

$$D = \frac{d_1}{\cos\theta_1} = \frac{d_2}{\cos\theta_2} \rightarrow d_2 = d_1\frac{\cos\theta_2}{\cos\theta_1} = (3.0\,\text{mm})\frac{\cos 16.36°}{\cos 25°} = \boxed{3.2\,\text{mm}}$$

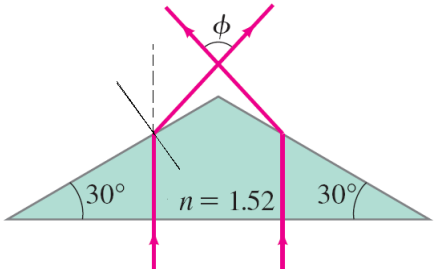
48. Find the angle θ_2 for the refraction at the first surface.

$n_{\text{air}} \sin\theta_1 = n\sin\theta_2$

$(1.00)\sin 45.0° = (1.54)\sin\theta_2 \rightarrow \theta_2 = 27.33°$

Find the angle of incidence at the second surface from the triangle formed by the two sides of the prism and the light path.

$(90° - \theta_2) + (90° - \theta_3) + A = 180° \rightarrow$



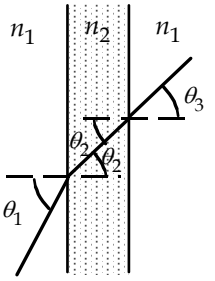
$\theta_3 = A - \theta_2 = 60° - 27.33° = 32.67°$

Use refraction at the second surface to find θ_4.

$n\sin\theta_3 = n_{\text{air}}\sin\theta_4 \rightarrow (1.54)\sin 32.67° = (1.00)\sin\theta_4 \rightarrow \theta_4 = \boxed{56.2°\text{ from the normal}}$

49. Since the angle of incidence at the base of the prism is 0^o, the rays are undeflected there. The angle of incidence at the upper face of the prism is 30^o. Use Snell's law to calculate the angle of refraction as the light exits the prism.

$n_1 \sin\theta_1 = \sin\theta_r \rightarrow \theta_r = \sin^{-1}(1.52\sin 30°) = 49.46°$



From the diagram, note that a normal to either top surface makes a 30° angle from the vertical. Subtracting 30° from the refracted angle will give the angle of the beam with respect to the vertical. By symmetry, the angle ϕ is twice the angle of the refracted beam from the vertical.

$\phi = 2(\theta_r - 30°) = 2(49.46° - 30°) = \boxed{38.9°}$

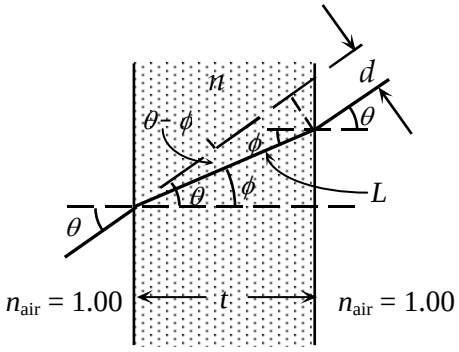
50. Because the surfaces are parallel, the angle of refraction from the first surface is the angle of incidence at the second. Thus for the two refractions, we have the following.



$n_1 \sin\theta_1 = n_2 \sin\theta_2$; $n_2 \sin\theta_2 = n_1 \sin\theta_3$

Substitute the second equation into the first.

$n_1 \sin\theta_1 = n_1 \sin\theta_3 \rightarrow \boxed{\theta_3 = \theta_1}$

Because the ray emerges in the same index of refraction, it is undeviated.

51. Because the glass surfaces are parallel, the exit beam will be traveling in the same direction as the original beam. Find the angle inside the glass from Snell's law, $n_{\text{air}} \sin\theta = n \sin\phi$. Since the angles are small, $\cos\phi \approx 1$ and $\sin\phi \approx \phi$, where ϕ is in radians.

$(1.00)\,\theta = n\phi \rightarrow \phi = \dfrac{\theta}{n}$

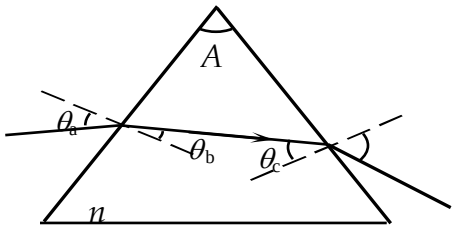
Find the distance along the ray in the glass from $L = \dfrac{t}{\cos\phi} \approx t$, and then find the perpendicular displacement from the original direction.

$$d = L\sin(\theta - \phi) \approx t(\theta - \phi) = t\left[\theta - \left(\frac{\theta}{n}\right)\right] = \boxed{\frac{t\theta(n-1)}{n}}$$

52. We find the speed of light from the speed of light in a vacuum divided by the index of refraction. Examining the graph we estimate that the index of refraction of 450 nm light in silicate flint glass is 1.643 and of 680 nm light is 1.613. There will be some variation in the answers due to estimation from the graph.

$$\frac{v_{\text{red}} - v_{\text{blue}}}{v_{\text{red}}} = \frac{c/n_{680} - c/n_{450}}{c/n_{680}} = \frac{1/1.613 - 1/1.643}{1/1.613} = 0.01826 \approx \boxed{1.8\%}$$

53. We find the angles of refraction in the glass from Snell's law, Eq. 32-5.



$(1.00)\sin 60.00° = (1.4831)\sin\theta_{2,\text{blue}} \rightarrow \theta_{2,\text{blue}} = 35.727°$

$(1.00)\sin 60.00° = (1.4754)\sin\theta_{2,\text{red}} \rightarrow \theta_{2,\text{red}} = 35.943°$ which gives $\theta_{2,700} = 35.943°$.

Thus the angle between the refracted beams is

$\theta_{2,\text{red}} - \theta_{2,\text{blue}} = 35.943° - 35.727° = 0.216° \approx \boxed{0.22°.}$

54. The indices of refraction are estimated from Figure 32-28 as 1.642 for 465 nm and 1.619 for 652 nm. Consider the refraction at the first surface.

$n_{\text{air}} \sin\theta_a = n \sin\theta_b \rightarrow$

$(1.00)\sin 45° = (1.642)\sin\theta_{b1} \rightarrow \theta_{b1} = 25.51°$

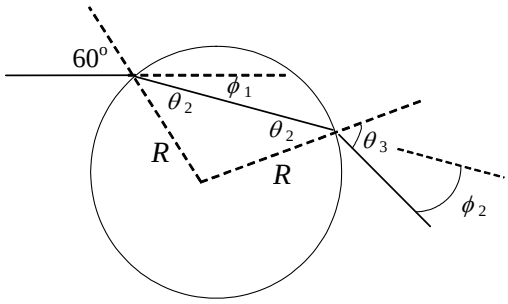
$(1.00)\sin 45° = (1.619)\sin\theta_{b2} \rightarrow \theta_{b2} = 25.90°$

We find the angle of incidence at the second surface from the upper triangle.

$(90° - \theta_b) + (90° - \theta_c) + A = 180° \rightarrow$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$\theta_{c1} = A - \theta_{b1} = 60.00° - 25.51° = 34.49°$; $\theta_{c2} = A - \theta_{b2} = 60.00° - 25.90° = 34.10°$



Apply Snell's law at the second surface.

$$n \sin\theta_c = n_{air} \sin\theta_d$$

$$(1.642)\sin 34.49° = (1.00)\sin\theta_{d1} \rightarrow \boxed{\theta_{d1} = 68.4° \text{ from the normal}}$$

$$(1.619)\sin 34.10° = (1.00)\sin\theta_{d2} \rightarrow \boxed{\theta_{d2} = 65.2° \text{ from the normal}}$$

55. At the first surface, the angle of incidence $\theta_1 = 60^o$ from air $(n_1 = 1.000)$ and the angle of refraction θ_2 into water $(n_2 = n)$ is found using Snell's law.

$$n_1 \sin\theta_1 = n_2 \sin\theta_2 \rightarrow$$

$$(1.000)\sin 60° = (n)\sin\theta_2 \rightarrow$$

$$\theta_2 = \sin^{-1}\left(\frac{\sin 60°}{n}\right)$$

Note that at this surface the ray has been deflected from its initial direction by angle $\phi_1 = 60° - \theta_2$. From the figure we see that the triangle that is interior to the drop is an isosceles triangle, so the angle of incidence from water $(n_2 = n)$ at the second surface is θ_2 and angle of refraction is θ_3 into air $(n_3 = 1.000)$. This relationship is identical to the relationship at the first surface, showing that the refracted angle as the light exits the drop is again 60°.

$$n_2 \sin\theta_2 = n_3 \sin\theta_3 \rightarrow (n)\sin\theta_2 = (1.000)\sin\theta_3 \rightarrow \sin\theta_3 = n\sin\theta_2 \rightarrow$$

$$\sin\theta_3 = n\left(\frac{\sin 60^o}{n}\right) = \sin 60^o \rightarrow \theta_3 = 60^o$$

Note that at this surface the ray has been deflected from its initial direction by the angle $\phi_2 = \theta_3 - \theta_2 = 60^o - \theta_2$. The total deflection of the ray is equal to the sum of the deflections at each surface.

$$\phi = \phi_1 + \phi_2 = \left(60^o - \theta_2\right) + \left(60^o - \theta_2\right) = 120^o - 2\theta_2 = 120^o - 2\sin^{-1}\left(\frac{\sin 60^o}{n}\right)$$

Inserting the indices of refraction for the two colors and subtracting the angles gives the difference in total deflection.

$$\Delta\phi = \phi_{violet} - \phi_{red} = \left\{120^o - 2\sin^{-1}\left[\frac{\sin 60^o}{n_{violet}}\right]\right\} - \left\{120^o - 2\sin^{-1}\left[\frac{\sin 60^o}{n_{red}}\right]\right\}$$

$$= 2\left\{\sin^{-1}\left[\frac{\sin 60^o}{n_{red}}\right] - \sin^{-1}\left[\frac{\sin 60^o}{n_{violet}}\right]\right\} = 2\left\{\sin^{-1}\left[\frac{\sin 60^o}{1.330}\right] - \sin^{-1}\left[\frac{\sin 60^o}{1.341}\right]\right\} = \boxed{0.80°}$$

56. (*a*) We solve Snell's law for the refracted angle. Then, since the index varies by only about 1%, we differentiate the angle with respect to the index of refraction to determine the spread in angle.

$$\sin\theta_1 = n\sin\theta_2 \rightarrow \theta_2 = \sin^{-1}\left(\frac{\sin\theta_1}{n}\right) \rightarrow$$

$$\frac{\Delta\theta_2}{\Delta n} \approx \frac{d\theta_2}{dn} = \frac{\sin\theta_1}{n^2\sqrt{1 - \dfrac{\sin^2\theta_1}{n^2}}} \rightarrow \boxed{\Delta\theta_2 = \frac{\Delta n}{n}\frac{\sin\theta_1}{\sqrt{n^2 - \sin^2\theta_1}}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We set $n = 1.5$ and $\theta_1 = 0° = 0\,\text{rad}$ and solve for the spread in refracted angle.

$$\Delta\theta_2 = \frac{\Delta n}{n}\frac{\sin\theta_1}{\sqrt{n^2 - \sin^2\theta_1}} = (0.01)\frac{\sin\ 0}{\sqrt{1.5^2 - \sin^2 0}} = \boxed{0}$$

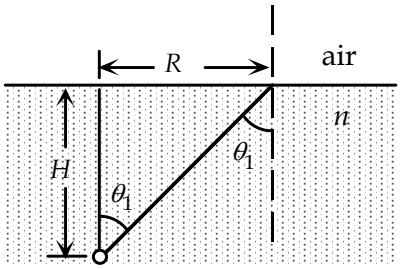
(*c*) We set $n = 1.5$ and $\theta_1 = 90°$ and solve for the spread in refracted angle. We must convert the spread from radians back to degrees.

$$\Delta\theta_2 = (0.01)\frac{\sin\ 90°}{\sqrt{1.5^2 - \sin^2 90°}} = 0.0089\ \text{rad}\left(\frac{180°}{\pi\ \text{rad}}\right) = \boxed{0.5°}$$

57. When the light in the material with a higher index is incident at the critical angle, the refracted angle is 90°. Use Snell's law.

$$n_{\text{diamond}}\sin\theta_1 = n_{\text{water}}\sin\theta_2 \quad\rightarrow\quad \theta_1 = \sin^{-1}\left(\frac{n_{\text{water}}}{n_{\text{diamond}}}\right) = \sin^{-1}\frac{1.33}{2.42} = \boxed{33.3°}$$

Because diamond has the higher index, the light must start in diamond.

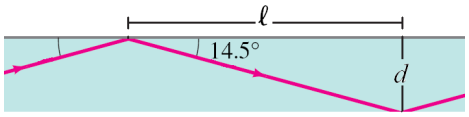


58. When the light in the liquid is incident at the critical angle, the refracted angle is 90°. Use Snell's law.

$$n_{\text{liquid}}\sin\theta_1 = n_{\text{air}}\sin\theta_2 \quad\rightarrow\quad n_{\text{liquid}} = n_{\text{air}}\frac{\sin\theta_2}{\sin\theta_1} = (1.00)\frac{1}{\sin 49.6°} = \boxed{1.31}$$

59. We find the critical angle for light leaving the water:

$$n_{\text{water}}\sin\theta_1 = n_{\text{air}}\sin\theta_2 \quad\rightarrow$$



$$\theta_1 = \sin^{-1}\left(\frac{n_{\text{air}}}{n_{\text{water}}}\right) = \sin^{-1}\frac{1.00}{1.33} = 48.75°$$

If the light is incident at a greater angle than this, it will totally reflect. Find R from the diagram.

$$R > H\tan\theta_1 = (72.0\,\text{cm})\tan 48.75° = \boxed{82.1\,\text{cm}}$$

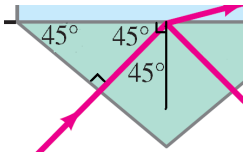
60. The ray reflects at the same angle, so each segment makes a 14.5° angle with the side. We find the distance ℓ between reflections from the definition of the tangent function.

$$\tan\theta = \frac{d}{\ell} \rightarrow \ell = \frac{d}{\tan\theta} = \frac{1.40\times10^{-4}\ \text{m}}{\tan\ 14.5°} = \boxed{5.41\times10^{-4}\ \text{m}}$$

61. We find the angle of incidence from the distances.

$$\tan\theta_1 = \frac{\ell}{h} = \frac{(7.6\,\text{cm})}{(8.0\,\text{cm})} = 0.95 \quad\rightarrow\quad \theta_1 = 43.53°$$

The relationship for the maximum incident angle for refraction from liquid into air gives this.



$$n_{\text{liquid}}\sin\theta_1 = n_{\text{air}}\sin\theta_2 \quad\rightarrow\quad n_{\text{liquid}}\sin\theta_{1\max} = (1.00)\sin 90° \quad\rightarrow\quad \sin\theta_{1\max} = \frac{1}{n_{\text{liquid}}}$$

Thus we have the following.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\sin\theta_1 \geq \sin\theta_{1\max} = \frac{1}{n_{\text{liquid}}} \quad \rightarrow \quad \sin 43.53^\circ = 0.6887 \geq \frac{1}{n_{\text{liquid}}} \quad \rightarrow \quad \boxed{n_{\text{liquid}} \geq 1.5}$$

62. For the device to work properly, the light should experience total internal reflection at the top surface of the prism when it is a prism to air interface, but not total internal reflection when the top surface is a prism to water interface. Since the incident ray is perpendicular to the lower surface of the prism, light does not experience refraction at that surface. As shown in the diagram, the incident angle for the upper surface will be 45°. We then use Eq. 32-7 to determine the minimum index of refraction for total internal reflection with an air interface, and the maximum index of refraction for a water interface. The usable indices of refraction will lie between these two values.

$$\frac{n_2}{n_1} = \sin\theta_c \quad \rightarrow \quad n_{1,\min} = \frac{n_{\text{air}}}{\sin\theta_c} = \frac{1.00}{\sin 45^\circ} = 1.41 \quad \rightarrow \quad n_{1,\max} = \frac{n_{\text{water}}}{\sin\theta_c} = \frac{1.33}{\sin 45^\circ} = 1.88$$

The index of refraction must fall within the range $1.41 < n < 1.88$. A Lucite prism will work.

63. (*a*) We calculate the critical angle using Eq. 32-7. We calculate the time for each ray to pass through the fiber by dividing the length the ray travels by the speed of the ray in the fiber. The length for ray A is the horizontal length of the fiber. The length for ray B is equal to the length of the fiber divided by the critical angle, since ray B is always traveling along a diagonal line at the critical angle relative to the horizontal. The speed of light in the fiber is the speed of light in a vacuum divided by the index of refraction in the fiber.

$$\sin\theta_c = \frac{n_2}{n_1} \; ; \; \Delta t = t_B - t_A = \frac{\ell_B}{v} - \frac{\ell_A}{v} = \frac{\ell_A}{v\sin\theta_c} - \frac{\ell_A}{v} = \frac{\ell_A}{c/n_1}\left(\frac{n_1}{n_2} - 1\right)$$

$$= \frac{(1.0\,\text{km})(1.465)}{(3.00\times10^5\,\text{km/s})}\left(\frac{1.465}{1.000} - 1\right) = \boxed{2.3\times10^{-6}\,\text{s}}$$

(*b*) We now replace the index of refraction of air (n = 1.000) with the index of refraction of the glass "cladding" (n = 1.460).

$$\Delta t = \frac{\ell_A n_1}{c}\left(\frac{n_1}{n_2} - 1\right) = \frac{(1.0\,\text{km})(1.465)}{3.00\times10^5\,\text{km/s}}\left(\frac{1.465}{1.460} - 1\right) = \boxed{1.7\times10^{-8}\,\text{s}}$$

64. (*a*) The ray enters normal to the first surface, so there is no deviation there. The angle of incidence is 45° at the second surface. When there is air outside the surface, we have the following.

$$n_1\sin\theta_1 = n_2\sin\theta_2 \quad \rightarrow \quad n_1\sin 45^\circ = (1.00)\sin\theta_2$$

For total internal reflection to occur, $\sin\theta_2 \geq 1$, and so $n_1 \geq \dfrac{1}{\sin 45^\circ} = \boxed{1.41}$.

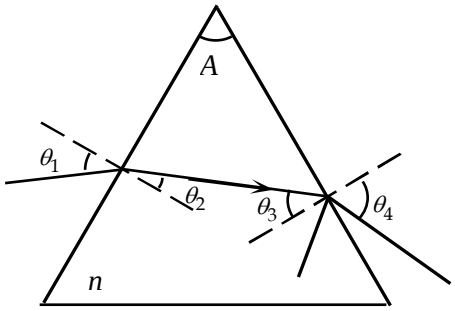
(*b*) When there is water outside the surface, we have the following.

$$n_1\sin\theta_1 = n_2\sin\theta_2 \quad \rightarrow \quad (1.58)\sin 45^\circ = (1.33)\sin\theta_2 \quad \rightarrow \quad \sin\theta_2 = 0.84$$

Because $\sin\theta_2 < 1$, the prism will not be totally reflecting.

(*c*) For total reflection when there is water outside the surface, we have the following.

$$n_1\sin\theta_1 = n_2\sin\theta_2 \quad \rightarrow \quad n_1\sin 45^\circ = (1.33)\sin\theta_2$$



$$n_1\sin 45^\circ = (1.33)\sin\theta_2.$$

For total internal reflection to occur, $\sin\theta_2 \geq 1$.

$$n_1 \geq \frac{1.33}{\sin 45^\circ} = \boxed{1.88}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

65. For the refraction at the first surface, we have the following.

$$n_{\text{air}} \sin\theta_1 = n \sin\theta_2 \;\rightarrow\; (1.00)\sin\theta_1 = n\sin\theta_2 \;\rightarrow$$

$$\sin\theta_2 = \sin\frac{\theta_1}{n}.$$

Find the angle of incidence at the second surface.

$$(90° - \theta_2) + (90° - \theta_3) + A = 180° \;\rightarrow$$

$$\theta_3 = A - \theta_2 = 60.0° - \theta_2$$

For the refraction at the second surface, we have this.

$$n\sin\theta_3 = n_{\text{air}} \sin\theta_4 = (1.00)\sin\theta_4$$

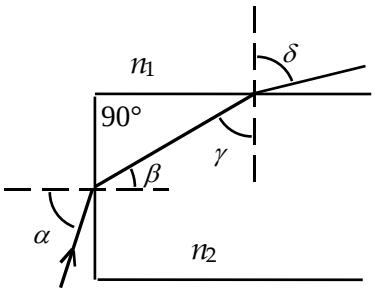
The maximum value of θ_4 before internal reflection takes place at the second surface is 90°. For internal reflection to occur, we have the following.

$$n\sin\theta_3 = n\sin(A - \theta_2) \geq 1 \;\rightarrow\; n(\sin A\cos\theta_2 - \cos A\sin\theta_2) \geq 1$$

Use the result from the first surface to eliminate *n*.

$$\frac{\sin\theta_1(\sin A\cos\theta_2 - \cos A\sin\theta_2)}{(\sin\theta_2)} = \sin\theta_1\left(\frac{\sin A}{\tan\theta_2 - \cos A}\right) \geq 1 \;\rightarrow$$

$$\frac{1}{\tan\theta_2} \geq \frac{\left[\left(\frac{1}{\sin\theta_1}\right) + \cos A\right]}{\sin A} = \frac{\left[\left(\frac{1}{\sin 45.0°}\right) + \cos 60.0°\right]}{\sin 60.0°} = 2.210 \;\rightarrow \text{ or}$$



$$\tan\theta_2 \leq 0.452 \;\rightarrow\; \theta_2 \leq 24.3°$$

Use the result from the first surface.

$$n_{\min} = \frac{\sin\theta_1}{\sin\theta_{2\max}} = \frac{\sin 45.0°}{\sin 24.3°} = 1.715 \;\rightarrow\; \boxed{n \geq 1.72}$$

66. For the refraction at the side of the rod, we have $n_2 \sin\gamma = n_1 \sin\delta$.

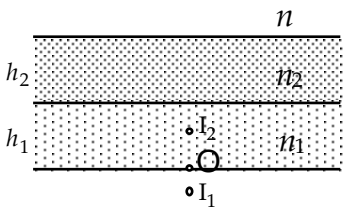
The minimum angle for total reflection $\gamma_{\min}$ occurs when $\delta = 90°$.

$$n_2 \sin\gamma_{\min} = (1.00)(1) = 1 \;\rightarrow\; \sin\gamma_{\min} = \frac{1}{n_2}$$

Find the maximum angle of refraction at the end of the rod.

$$\beta_{\max} = 90° - \gamma_{\min}$$

Because the sine function increases with angle, for the refraction at the end of the rod, we have the following.



$$n_1 \sin\alpha_{\max} = n_2 \sin\beta_{\max} \;\rightarrow\; (1.00)\sin\alpha_{\max} = n_2 \sin(90° - \gamma_{\min}) = n_2 \cos\gamma_{\min}$$

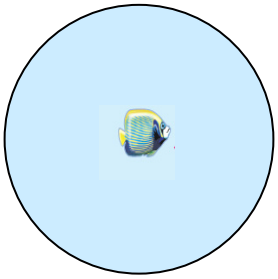
If we want total internal reflection to occur for any incident angle at the end of the fiber, the maximum value of α is 90°, so $n_2 \cos\gamma_{\min} = 1$. When we divide this by the result for the refraction at the side, we get $\tan\gamma_{\min} = 1 \;\rightarrow\; \gamma_{\min} = 45°$. Thus we have the following.

$$\boxed{n_2 \geq \frac{1}{\sin\gamma_{\min}} = \frac{1}{\sin 45°} = 1.414}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

67. We find the location of the image of a point on the bottom from the refraction from water to glass, using Eq. 32-8, with $R = \infty$.

$$\frac{n_1}{d_o} + \frac{n_2}{d_i} = \frac{n_2 - n_1}{R} = 0 \quad \rightarrow$$



$$d_i = -\frac{n_2 d_o}{n_1} = -\frac{1.58(12.0\,\text{cm})}{1.33} = -14.26\,\text{cm}$$

Using this image distance from the top surface as the object for the refraction from glass to air gives the final image location, which is the apparent depth of the water.

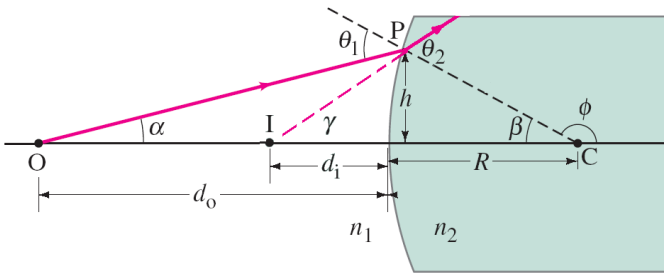
$$\frac{n_2}{d_{o2}} + \frac{n_3}{d_{i2}} = \frac{n_3 - n_2}{R} = 0 \quad \rightarrow \quad d_{i2} = -\frac{n_3 d_{o2}}{n_2} = -\frac{1.00(13.0\,\text{cm} + 14.26\,\text{cm})}{1.58} = -17.25\,\text{cm}$$

Thus the bottom appears to be 17.3 cm below the surface of the glass. In reality it is 25 cm.

68. (*a*) We use Eq. 32-8 to calculate the location of the image of the fish. We assume that the observer is outside the circle in the diagram, to the right of the diagram. The fish is located at the center of the sphere so the object distance is 28.0 cm. Since the glass is thin we use the index of refraction of the water and of the air. Index 1 refers to the water, and index 2 refers to the air. The radius of curvature of the right side of the bowl is negative.

$$\frac{n_1}{d_o} + \frac{n_2}{d_i} = \frac{n_2 - n_1}{R} \quad \rightarrow$$

$$d_i = n_2\left[\frac{n_2 - n_1}{R} - \frac{n_1}{d_o}\right]^{-1} = 1.00\left[\frac{1.00 - 1.33}{-28.0\,\text{cm}} - \frac{1.33}{28.0\,\text{cm}}\right]^{-1} = \boxed{-28.0\,\text{cm}}$$



The image is also at the center of the bowl. When the fish is at the center of the bowl, all small-angle light rays traveling outward from the fish are approximately perpendicular to the surface of the bowl, and therefore do not refract at the surface. This causes the image of the fish to also be located at the center of the bowl.

(*b*) We repeat the same calculation as above with the object distance 20.0 from the right side of the bowl, so $d_o = 20.0\,\text{cm}$.

$$d_i = n_2\left[\frac{n_2 - n_1}{R} - \frac{n_1}{d_o}\right]^{-1} = 1.00\left[\frac{1.00 - 1.33}{-28.0\,\text{cm}} - \frac{1.33}{20.0\,\text{cm}}\right]^{-1} = \boxed{-18.3\,\text{cm}}$$

The fish appears closer to the center of the bowl than it actually is.

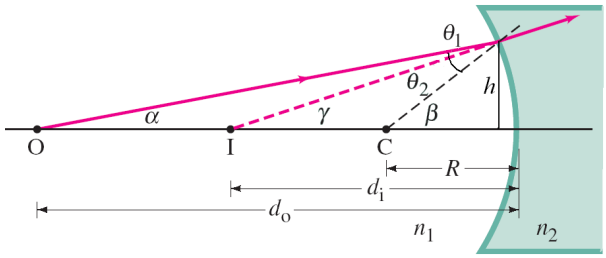
69. (*a*) The accompanying figure shows a light ray originating at point O and entering the convex spherical surface at point P. In this case $n_2 < n_1$. The ray bends away from the normal and creates a virtual image at point I. From the image and supplementary angles we obtain the relationships between the angles.

$$\theta_1 = \alpha + \beta \qquad \theta_2 = \gamma + \beta$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

We then use Snell's law to relate the incident and refracted angle. For this derivation we assume these are small angles.

$$n_1 \sin\theta_1 = n_2 \sin\theta_2 \quad \rightarrow \quad n_1\theta_1 = n_2\theta_2$$



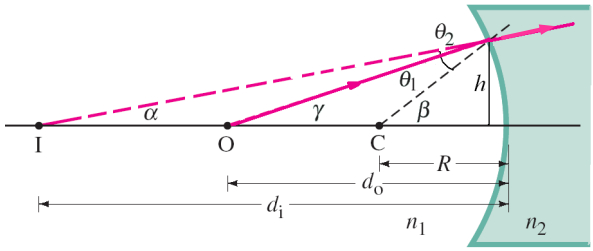
From the diagram we can create three right triangles, each with height h and lengths d_o, d_i, and R. Again, using the small angle approximation we obtain a relationship between the angles and lengths. Combining these definitions to eliminate the angles we obtain Eq. 32-8, noting that by our definition d_i is a negative value.

$$\alpha = \frac{h}{d_o} \;;\; \gamma = \frac{h}{R} \;;\; \beta = \frac{h}{(-d_i)}$$

$$n_1\theta_1 = n_2\theta_2 \quad \rightarrow \quad n_1(\alpha+\beta) = n_2(\gamma+\beta) = n_1\alpha + n_1\beta = n_2\gamma + n_2\beta \quad \rightarrow$$

$$n_1\frac{h}{d_o} + n_1\frac{h}{R} = n_2\frac{h}{(-d_i)} + n_2\frac{h}{R} \quad \rightarrow \quad \boxed{\frac{n_1}{d_o} + \frac{n_2}{d_i} = \frac{n_2 - n_1}{R}}$$

(*b*) This image shows a concave surface with $n_2 > n_1$. Again, we use the approximation of small angles and sign convention that $R < 0$ and $d_i < 0$. We write relationships between the angles using supplementary angles, Snell's law, and right triangles. Combining these equations to eliminate the angles we arrive at Eq. 32-8.

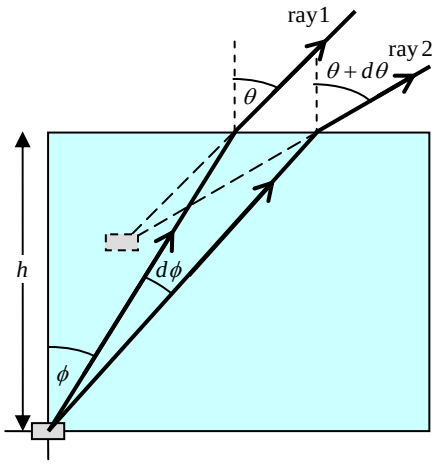


$$\theta_1 = \beta - \alpha \;;\; \theta_2 = \beta - \gamma \;;\; \alpha = \frac{h}{d_o} \;;\; \gamma = \frac{h}{(-d_i)} \;;\; \beta = \frac{h}{(-R)}$$

$$n_1\theta_1 = n_2\theta_2 \quad \rightarrow \quad n_1(\beta-\alpha) = n_2(\beta-\gamma) = n_1\beta - n_1\alpha = n_2\beta - n_2\gamma \quad \rightarrow$$

$$n_1\frac{h}{(-R)} - n_1\frac{h}{d_o} = n_2\frac{h}{(-R)} - n_2\frac{h}{(-d_i)} \quad \rightarrow \quad \boxed{\frac{n_1}{d_0} + \frac{n_2}{d_i} = \frac{n_2 - n_1}{R}}$$

(*c*) This image shows a concave surface with $n_2 < n_1$. Again, we use the approximation of small angles and sign convention that $R < 0$ and $d_i < 0$. We write relationships between the angles using supplementary angles, Snell's law, and right triangles. Combining these equations to eliminate the angles we arrive at Eq. 32-8.



$$\theta_1 = \beta - \gamma \;;\; \theta_2 = \beta - \alpha \;;\; \alpha = \frac{h}{(-d_i)} \;;\; \gamma = \frac{h}{d_o} \;;\; \beta = \frac{h}{(-R)}$$

$$n_1\theta_1 = n_2\theta_2 \quad \rightarrow \quad n_1(\beta-\gamma) = n_2(\beta-\alpha) = n_1\beta - n_1\gamma = n_2\beta - n_2\alpha \quad \rightarrow$$

$$n_1\frac{h}{(-R)} - n_1\frac{h}{d_o} = n_2\frac{h}{(-R)} - n_2\frac{h}{(-d_i)} \quad \rightarrow \quad \boxed{\frac{n_1}{d_o} + \frac{n_2}{d_i} = \frac{n_2 - n_1}{R}}$$

70. We consider two rays leaving the coin. These rays refract upon leaving the surface and reach the observer's eye with angles of refraction all very near $\theta = 45°$. Let the origin of coordinates be at the actual location of the coin. We will write straight-line equations for each of two refracted rays, one with a refraction angle of θ and the other with a refraction angle of $\theta + d\theta$, and extrapolate them back to where they intersect to find the location of the image. We utilize the relationship $f(x+dx) = f(x) + \left(\frac{df}{dx}\right)dx$.

First, apply Snell's law to both rays.
Ray # 1, leaving the coin at angle ϕ.

$$n\sin\phi = \sin\theta$$

Ray # 2, leaving the coin at angle $\phi + d\phi$.

$$n\sin(\phi + d\phi) = \sin(\theta + d\theta)$$

Note the following relationship involving the differential angles.

$$\sin(\phi + d\phi) = \sin\phi + \frac{d(\sin\phi)}{d\phi}d\phi = \sin\phi + \cos\phi d\phi \;\; ; \;\; \sin(\theta + d\theta) = \sin\theta + \cos\theta d\theta$$

So for Ray # 2, we would have the following Snell's law relationship.

$$n[\sin\phi + \cos\phi d\phi] = [\sin\theta + \cos\theta d\theta] \;\rightarrow\; n\sin\phi + n\cos\phi d\phi = \sin\theta + \cos\theta d\theta \;\rightarrow$$

$$n\cos\phi d\phi = \cos\theta d\theta \;\rightarrow\; d\phi = \frac{\cos\theta}{n\cos\phi}d\theta$$

This relationship between $d\phi$ and $d\theta$ will be useful later in the solution.
Ray # 1 leaves the water at coordinates $x_1 = h\tan\phi$, $y_1 = h$ and has a slope after it leaves the water of $m_1 = \tan(90° - \theta) = \cot\theta$. Thus a straight-line equation describing ray # 1 after it leaves the water is as follows.

$$y - y_1 = (x - x_1)m_1 \;\rightarrow\; y = h + (x - h\tan\phi)\cot\theta$$

Ray # 2 leaves the water at the following coordinates.

$$x_2 = h\tan(\phi + d\phi) = h\left[\tan\phi + \frac{d(\tan\phi)}{d\phi}d\phi\right] = h[\tan\phi + \sec^2\phi d\phi],\; y_2 = h$$

Ray # 2 has the following slope after it leaves the water.

$$m_2 = \tan[90° - (\theta + d\theta)] = \cot(\theta + d\theta) = \cot\theta + \frac{d(\cot\theta)}{d\theta}d\theta = \cot\theta - \csc^2\theta d\theta$$

Thus a straight-line equation describing ray # 2 after it leaves the water is as follows.

$$y - y_2 = (x - x_2)m_2 \;\rightarrow\; y = h + \left(x - h[\tan\phi + \sec^2\phi d\phi]\right)[\cot\theta - \csc^2\theta d\theta]$$

To find where these rays intersect, which is the image location, set the two expressions for *y* equal to each other.

$$h + (x - h\tan\phi)\cot\theta = h + \left(x - h[\tan\phi + \sec^2\phi d\phi]\right)[\cot\theta - \csc^2\theta d\theta] \;\rightarrow$$

Expanding the terms and subtracting common terms gives us the following.

$$x\csc^2\theta d\theta = h\tan\phi\csc^2\theta d\theta - h\sec^2\phi d\phi\cot\theta + h\sec^2\phi d\phi\csc^2\theta d\theta$$

The first three terms each have a differential factor, but the last term has two differential factors.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

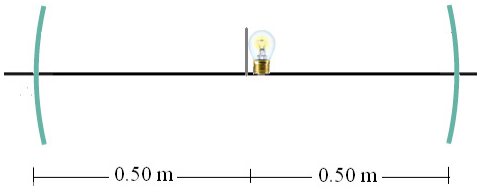
That means the last term is much smaller than the other terms, and so can be ignored. So we delete the last term, and use the relationship between the differentials derived earlier.

$$x\csc^2\theta d\theta = h\tan\phi\csc^2\theta d\theta - h\sec^2\phi d\phi\cot\theta \quad ; \quad d\phi = \frac{\cos\theta}{n\cos\phi}d\theta \quad \rightarrow$$

$$x\csc^2\theta d\theta = h\tan\phi\csc^2\theta d\theta - h\sec^2\phi\frac{\cos\theta}{n\cos\phi}d\theta\cot\theta$$

$$x = h\left[\tan\phi - \sec^2\phi\frac{\cos\theta}{n\cos\phi}\frac{\cot\theta}{\csc^2\theta}\right] = h\left[\tan\phi - \frac{\cos^2\theta\sin\theta}{n\cos^3\phi}\right]$$

Now we may substitute in values. We know that $\theta = 45°$ and $h = 0.75\,\text{m}$. We use the original relationship for ray # 1 to solve for ϕ. And once we solve for *x*, we use the straight-line equation for ray # 1 to solve for *y*.



$$n\sin\phi = \sin\theta \quad \rightarrow \quad \phi = \sin^{-1}\frac{\theta}{n} = \sin^{-1}\frac{\sin 45°}{1.33} = 32.12°$$

$$x = h\left[\tan\phi - \frac{\cos^2\theta\sin\theta}{n\cos^3\phi}\right] = 0.75\left[\tan 32.12 - \frac{\cos^2 45\sin 45}{1.33\cos^3 32.12}\right] = 0.1427\,\text{m}$$

$$y = h + (x - h\tan\phi)\cot\theta = 0.75 + (0.1427 - 0.75\tan 32.12)\cot 45 = 0.4264\,\text{m}$$

The image of the coin is located 0.14 m toward the viewer and 0.43 m above the actual coin.

71. Use Eq. 32-2 to determine the location of the image from the right mirror, in terms of the focal length. Since this distance is measured from the right mirror, we subtract that distance from the separation distance between the two mirrors to obtain the object distance for the left mirror. We then insert this object distance back into Eq. 32-2, with the known image distance and combine terms to write a quadratic equation for the focal length.

$$\frac{1}{f} = \frac{1}{d_{o1}} + \frac{1}{d_{i1}} \quad \rightarrow \quad d_{i1} = \left(\frac{1}{f} - \frac{1}{d_{o1}}\right)^{-1} = \frac{fd_{o1}}{d_{o1} - f}$$

$$d_{o2} = D - d_{i1} = D - \frac{fd_{o1}}{d_{o1} - f} = \frac{Dd_{o1} - fD - fd_{o1}}{d_{o1} - f}$$

$$\frac{1}{f} = \frac{1}{d_{o2}} + \frac{1}{d_{i2}} = \frac{d_{o1} - f}{Dd_{o1} - fD - fd_{o1}} + \frac{1}{d_{i2}} = \frac{d_{i2}d_{o1} - fd_{i2} + Dd_{o1} - fD - fd_{o1}}{d_{i2}(Dd_{o1} - fD - fd_{o1})}$$

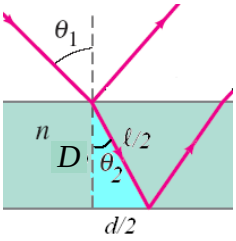
$$d_{i2}(Dd_{o1} - fD - fd_{o1}) = d_{i2}d_{o1}f - f^2d_{i2} + fDd_{o1} - f^2D - f^2d_{o1}$$

$$f^2[d_{i2} + D + d_{o1}] - f[2d_{i2}d_{o1} + Dd_{o1} + Dd_{i2}] + Dd_{o1}d_{i2} = 0$$

We insert the values for the initial object distance, final image distance, and mirror separation distance and then solve the quadratic equation.

$$f^2[0.50\,\text{m} + 1.00\,\text{m} + 0.50\,\text{m}] - f\left[2(0.50\,\text{m})^2 + 2(1.00\,\text{m})(0.50\,\text{m})\right] + (1.00\,\text{m})(0.50\,\text{m})^2 = 0$$

$$(2.00\,\text{m})f^2 - (1.50\,\text{m}^2)f + 0.25\,\text{m}^3 = 0$$



$$f = \frac{1.50\,\text{m}^2 \pm \sqrt{(1.50\,\text{m}^2)^2 - 4(2.00\,\text{m})(0.25\,\text{m}^3)}}{2(2.00\,\text{m})} = \boxed{0.25\,\text{m} \text{ or } 0.50\,\text{m}}$$

If the focal length is 0.25 m, the right mirror creates an image at the location of the object. With the paper in place, this image would be blocked out. With a focal length of 0.50 m, the light from the

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

right mirror comes out as parallel light. No image is formed from the right mirror. When this parallel light enters the second mirror it is imaged at the focal point (0.50 m) of the second mirror.

72. (*a*) We use Snell's law to calculate the refracted angle within the medium. Then using the right triangle formed by the ray within the medium, we can use the trigonometric identities to write equations for the horizontal displacement and path length.

$$\sin\theta_1 = n\sin\theta_2 \quad \rightarrow \quad \sin\theta_2 = \frac{\sin\theta_1}{n}$$

$$\cos\theta_2 = \frac{D}{\ell/2} \quad \rightarrow \quad \ell = \frac{2D}{\cos\theta_2} = \frac{2D}{\sqrt{1-\sin^2\theta_2}} = \boxed{\frac{2nD}{\sqrt{n^2-\sin^2\theta_1}}}$$

$$\sin\theta_2 = \frac{d/2}{\ell/2} \quad \rightarrow \quad d = \ell\sin\theta_2 = \frac{2nD}{\sqrt{n^2-\sin^2\theta_1}}\frac{\sin\theta_1}{n} = \boxed{\frac{2D\sin\theta_1}{\sqrt{n^2-\sin^2\theta_1}}}$$

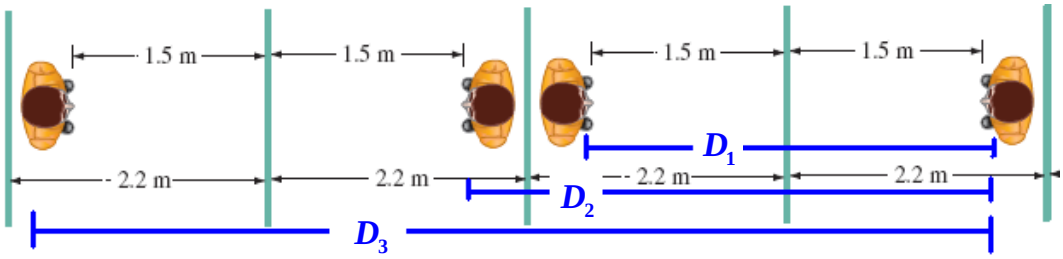
(*b*) Evaluate the above expressions for $\theta_1 = 0°$.

$$\ell = \frac{2nD}{\sqrt{n^2-\sin^2\theta_1}} = \frac{2nD}{\sqrt{n^2}} = 2D \;;\; \sin\theta_2 = \frac{d/2}{\ell/2} \quad \rightarrow \quad d = \frac{2D\sin\theta_1}{\sqrt{n^2-\sin^2\theta_1}} = 0$$

These are the expected values.

73. (*a*) The first image seen will be due to a single reflection off the front glass. This image will be equally far behind the mirror as you are in front of the mirror.

$D_1 = 2\times 1.5 \text{ m} = \boxed{3.0 \text{ m}}$



The second image seen will be the image reflected once off the front mirror and once off the back mirror. As seen in the diagram, this image will appear to be twice the distance between the mirrors.

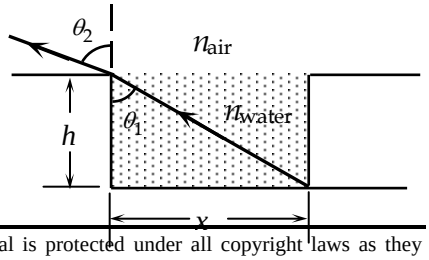
$D_2 = 1.5 \text{ m} + 2.2 \text{ m} + (2.2 \text{ m} - 1.5 \text{ m}) = 2\times 2.2 \text{ m} = \boxed{4.4 \text{ m}}$

The third image seen will be the image reflected off the front mirror, the back mirror, and off the front mirror again. As seen in the diagram this image distance will be the sum of twice your distance to the mirror and twice the distance between the mirrors.

$D_3 = 1.5 \text{ m} + 2.2 \text{ m} + 2.2 \text{ m} + 1.5 \text{ m} = 2\times 1.5 \text{ m} + 2\times 2.2 \text{ m} = \boxed{7.4 \text{ m}}$

The actual person is to the far right in the diagram.

(*b*) We see from the diagram that the first image is facing toward you; the second image is facing away from you; and the third image is facing toward you.

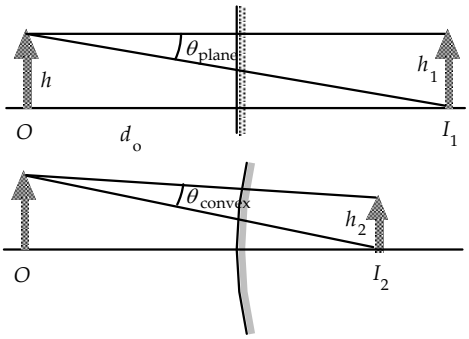


74. Find the angle of incidence for refraction from water into air.

$n_{\text{water}}\sin\theta_1 = n_{\text{air}}\sin\theta_2 \quad \rightarrow$

$(1.33)\sin\theta_1 = (1.00)\sin(90.0° - 13.0°) \quad \rightarrow \quad \theta_1 = 47.11°$

$(1.33)\sin\theta_1 = (1.00)\sin(90.0° - 13.0°),$



We find the depth of the pool from $\tan\theta_1 = x/h$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\tan 47.11° = (5.50\,\text{m})/h \quad \rightarrow \quad h = \boxed{5.11\,\text{m}}$$

75. The apparent height of the image is related to the angle subtended by the image. For small angles, this angle is the height of the image divided by the distance between the image and viewer. Since both images are virtual, which gives a negative image distance, the image to viewer (object) distance will be the object distance minus the image distance. For the plane mirror the object and image heights are the same, and the image distance is the negative of the object distance.

$$h_i = h_o \;\; ; \;\; d_i = -d_o \;\; ; \;\; \theta_{\text{plane}} = \frac{h_i}{d_o - d_i} = \frac{h_o}{2d_o}$$

We use Eq. 32-2 and 32-3 to write the angle of the image in the convex mirror in terms of the object size and distance.

$$\frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} \quad \rightarrow \quad d_i = \frac{d_o f}{d_o - f} \quad \rightarrow \quad d_o - d_i = \frac{d_o^2 - 2d_o f}{d_o - f}$$

$$\frac{h_i}{h_o} = -\frac{d_i}{d_o} \quad \rightarrow \quad h_i = -\frac{h_o d_i}{d_o} = -\frac{h_o f}{d_o - f}$$

$$\theta_{\text{convex}} = \frac{h_i}{d_o - d_i} = -\left(\frac{h_o f}{d_o - f}\right)\left(\frac{d_o - f}{d_o^2 - 2d_o f}\right) = \frac{-h_o f}{d_o^2 - 2d_o f}$$

We now set the angle in the convex mirror equal to ½ of the angle in the plane mirror and solve for the focal length.

$$\theta_{\text{convex}} = \tfrac{1}{2}\theta_{\text{plane}} \quad \rightarrow \quad \frac{-h_o f}{d_o^2 - 2d_o f} = \frac{h_o}{4d_o} \quad \rightarrow \quad -4d_o f = d_o^2 - 2d_o f \quad \rightarrow \quad f = -\tfrac{1}{2}d_o$$

We use Eq. 32-1 to calculate the radius of the mirror.

$$r = 2f = 2\left(-\tfrac{1}{2}d_o\right) = -d_o = \boxed{-3.80\,\text{m}}$$

76. For the critical angle, the refracted angle is 90°. For the refraction from plastic to air, we have the following.

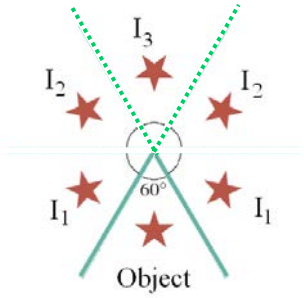
$$n_{\text{plastic}} \sin\theta_{\text{plastic}} = n_{\text{air}} \sin\theta_{\text{air}} \quad \rightarrow \quad n_{\text{plastic}} \sin 39.3° = (1.00)\sin 90° \quad \rightarrow \quad n_{\text{plastic}} = 1.5788$$

For the refraction from plastic to water, we have the following.

$$n_{\text{plastic}} \sin\theta'_{\text{plastic}} = n_{\text{water}} \sin\theta_{\text{water}} \quad \rightarrow \quad (1.5788)\sin\theta'_{\text{plastic}} = (1.33)\sin 90° \quad \rightarrow \quad \theta'_{\text{plastic}} = \boxed{57.4°}$$

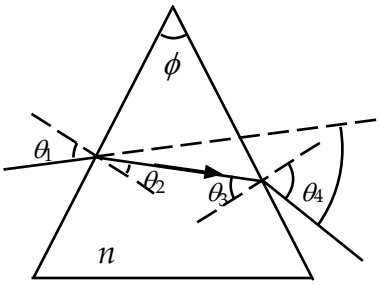
77. The two students chose different signs for the magnification, i.e., one upright and one inverted. The focal length of the concave mirror is $f = \frac{1}{2}R = \frac{1}{2}(46\,\text{cm}) = 23\,\text{cm}$. We relate the object and image distances from the magnification.

$$m = -\frac{d_i}{d_o} \quad \rightarrow \quad \pm 3 = -\frac{d_i}{d_o} \quad \rightarrow \quad d_i = \mp 3d_o$$



Use this result in the mirror equation.

$$\left(\frac{1}{d_o}\right) + \left(\frac{1}{d_i}\right) = \frac{1}{f} \quad \rightarrow \quad \left(\frac{1}{d_o}\right) + \left[\frac{1}{(\mp 3d_o)}\right] = \frac{1}{f} \quad \rightarrow \quad d_o = \frac{2f}{3}, \frac{4f}{3} = 15.3\,\text{cm}, 30.7\,\text{cm}$$



So the object distances are 15 cm (produces virtual image), and +31 cm (produces real image).

78. The object "creates" the I_1 images as reflections from the actual mirrors. The I_2 images can be considered as images of the I_1 "objects," formed by the original mirrors. A specific I_2 image is the image of the I_1 "object" that is diametrically opposite it. Then the I_3 image can be considered as an image of the I_2 "objects." Each I_2 "object" would make the I_3 "image" at the same location. We can consider the extension of the actual mirrors, shown as dashed lines, to help understand the image formation.

79. The total deviation of the beam is the sum of the deviations at each surface. The deviation at the first surface is the refracted angle θ_2 subtracted from the incident angle θ_1. The deviation at the second surface is the incident angle θ_3 subtracted from the refracted angle θ_4. This gives the total deviation.

$$\delta = \delta_1 + \delta_2 = \theta_1 - \theta_2 + \theta_4 - \theta_3$$

We will express all of the angles in terms of θ_2. To minimize the deviation, we will take the derivative of the deviation with respect to θ_2, and then set that derivative equal to zero. Use Snell's law at the first surface to write the incident angle in terms of the refracted angle.

$$\sin\theta_1 = n\sin\theta_2 \quad \rightarrow \quad \theta_1 = \sin^{-1}\left(n\sin\theta_2\right)$$

The angle of incidence at the second surface is found using complementary angles, such that the sum of the refracted angle from the first surface and the incident angle at the second surface must equal the apex angle.

$$\phi = \theta_2 + \theta_3 \quad \rightarrow \quad \theta_3 = \phi - \theta_2$$

The refracted angle from the second surface is again found using Snell's law with the deviation in angle equal to the difference between the incident and refracted angles at the second surface.

$$n\sin\theta_3 = \sin\theta_4 \quad \rightarrow \quad \theta_4 = \sin^{-1}\left(n\sin\theta_3\right) = \sin^{-1}\left(n\sin\left(\phi - \theta_2\right)\right)$$

Inserting each of the angles into the deviation and setting the derivative equal to zero allows us to solve for the angle at which the deviation is a minimum.

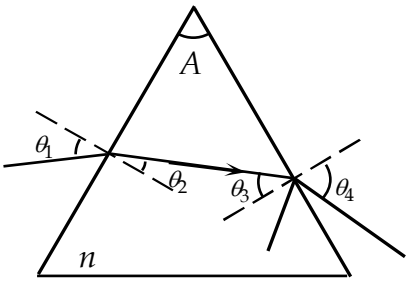
$$\delta = \sin^{-1}\left(n\sin\theta_2\right) - \theta_2 + \sin^{-1}\left(n\sin\left(\phi - \theta_2\right)\right) - \left(\phi - \theta_2\right)$$

$$= \sin^{-1}\left(n\sin\theta_2\right) + \sin^{-1}\left(n\sin\left(\phi - \theta_2\right)\right) - \phi$$

$$\frac{d\delta}{d\theta_2} = \frac{n\cos\theta_2}{\sqrt{1 - n^2\sin^2\theta_2}} - \frac{n\cos\left(\phi - \theta_2\right)}{\sqrt{1 - n^2\sin^2\left(\phi - \theta_2\right)}} = 0 \quad \rightarrow \quad \theta_2 = \phi - \theta_2 \quad \rightarrow \quad \theta_2 = \theta_3 = \tfrac{1}{2}\phi$$

In order for $\theta_2 = \theta_3$, the ray must pass through the prism horizontally, which is perpendicular to the bisector of the apex angle ϕ. Set $\theta_2 = \frac{1}{2}\phi$ in the deviation equation (for the minimum deviation, δ_m) and solve for the index of refraction.

$$\delta_m = \sin^{-1}\left(n\sin\theta_2\right) + \sin^{-1}\left(n\sin\left(\phi - \theta_2\right)\right) - \phi$$



$$= \sin^{-1}\left(n\sin\tfrac{1}{2}\phi\right) + \sin^{-1}\left(n\sin\tfrac{1}{2}\phi\right) - \phi = 2\sin^{-1}\left(n\sin\tfrac{1}{2}\phi\right) - \phi$$

$$\rightarrow \boxed{n = \frac{\sin\left(\frac{1}{2}\left(\delta_m + \phi\right)\right)}{\sin\frac{1}{2}\phi}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

80. For the refraction at the second surface, we have this.

$$n\sin\theta_3 = n_{\text{air}}\sin\theta_4 \quad\rightarrow\quad (1.58)\sin\theta_3 = (1.00)\sin\theta_4$$

The maximum value of θ_4 before internal reflection takes place at the second surface is 90°. Thus for internal reflection not to occur, we have

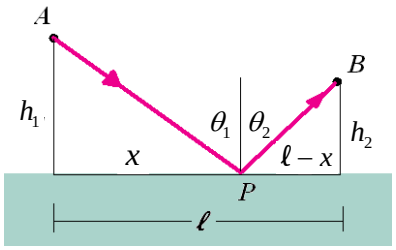
$$(1.58)\sin\theta_3 \le 1.00 \quad\rightarrow\quad \sin\theta_3 \le 0.6329 \quad\rightarrow\quad \theta_3 \le 39.27°$$

We find the refraction angle at the second surface.

$$(90° - \theta_2) + (90° - \theta_3) + A = 180° \quad\rightarrow$$

$$\theta_2 = A - \theta_3 = 72° - \theta_3$$

Thus $\theta_2 \ge 72° - 39.27° = 32.73°$.



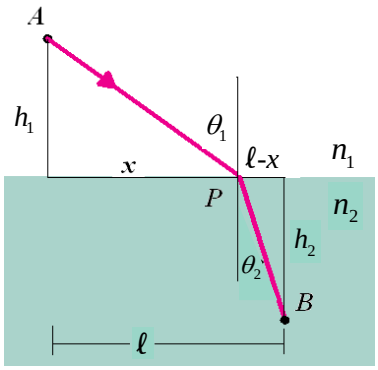
For the refraction at the first surface, we have the following.

$$n_{\text{air}}\sin\theta_1 = n\sin\theta_2 \quad\rightarrow\quad (1.00)\sin\theta_1 = (1.58)\sin\theta_2 \quad\rightarrow\quad \sin\theta_1 = (1.50)\sin\theta_2$$

Now apply the limiting condition.

$$\sin\theta_1 \ge (1.58)\sin 32.73° = 0.754 \quad\rightarrow\quad \boxed{\theta_1 \ge 58.69°}$$

81. (*a*) Consider the light ray shown in the figure. A ray of light starting at point A reflects off the surface at point P before arriving at point B, a horizontal distance ℓ from point A. We calculate the length of each path and divide the length by the speed of light to determine the time required for the light to travel between the two points.



$$t = \frac{\sqrt{x^2 + h_1^2}}{c} + \frac{\sqrt{(\ell - x)^2 + h_2^2}}{c}$$

To minimize the time we set the derivative of the time with respect to *x* equal to zero. We also use the definition of the sine as opposite side over hypotenuse to relate the lengths to the angles of incidence and reflection.

$$0 = \frac{dt}{dx} = \frac{x}{c\sqrt{x^2 + h_1^2}} + \frac{-(\ell - x)}{c\sqrt{(\ell - x)^2 + h_2^2}} \quad\rightarrow$$

$$\frac{x}{\sqrt{x^2 + h_1^2}} = \frac{(\ell - x)}{\sqrt{(\ell - x)^2 + h_2^2}} \quad\rightarrow\quad \sin\theta_1 = \sin\theta_2 \quad\rightarrow\quad \boxed{\theta_1 = \theta_2}$$

(*b*) Now we consider a light ray traveling from point A to point B in media with different indices of refraction, as shown in the figure. The time to travel between the two points is the distance in each medium divided by the speed of light in that medium.

$$t = \frac{\sqrt{x^2 + h_1^2}}{c/n_1} + \frac{\sqrt{(\ell - x)^2 + h_2^2}}{c/n_2}$$

To minimize the time we set the derivative of the time with respect to *x* equal to zero. We also use the definition of the sine as opposite side over hypotenuse to relate the lengths to the angles of incidence and reflection.

$$0=\frac{dt}{dx}=\frac{n_1 x}{c\sqrt{x^2+h_1^2}}+\frac{-n_2(\ell-x)}{c\sqrt{(\ell-x)^2+h_2^2}}\rightarrow\frac{n_1 x}{\sqrt{x^2+h_1^2}}=\frac{n_2(\ell-x)}{\sqrt{(\ell-x)^2+h_2^2}}\rightarrow\boxed{n_1\sin\theta_1=n_2\sin\theta_2}$$

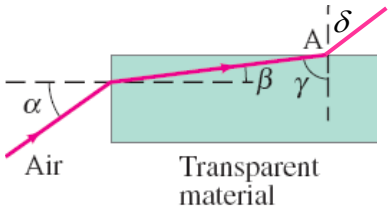
82. We use Eq. 32-8 to calculate the location of the image and Eq. 32-3 to calculate the height of the image.

$$\frac{n_1}{d_o}+\frac{n_2}{d_i}=\frac{n_2-n_1}{R}\rightarrow d_i=n_2\left[\frac{n_2-n_1}{R}-\frac{n_1}{d_o}\right]^{-1}=1.53\left[\frac{1.53-1.33}{2.00\,\text{cm}}-\frac{1.33}{23\text{cm}}\right]^{-1}=\boxed{36.3\text{cm}}$$

$$\frac{h_i}{h_o}=-\frac{d_i}{d_o}\rightarrow h_i=-h_o\frac{d_i}{d_o}=-(2.0\,\text{mm})\frac{36.3\text{cm}}{23\text{cm}}=\boxed{3.2\,\text{mm}}$$

83. A ray of light initially on the inside of the beam will strike the far surface at the smallest angle, as seen in the associated figure. The angle is found using the triangle shown in the figure, with side r and hypotenuse $r+d$. We set this angle equal to the critical angle, using Eq. 32-7, and solve for the minimum radius of curvature.

$$\sin\theta_C=\frac{r}{r+d}=\frac{n_2}{n_1}=\frac{1}{n}\rightarrow\boxed{r=\frac{d}{n-1}}$$



84. A relationship between the image and object distances can be obtained from the given information.

$$m=-\frac{1}{2}=-\frac{d_i}{d_o}\quad\rightarrow\quad d_i=\tfrac{1}{2}d_o=\boxed{7.5\text{cm}}$$

Now we find the focal length and the radius of curvature.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}\quad\rightarrow\quad\frac{1}{15\text{cm}}+\frac{1}{7.5\text{cm}}=\frac{1}{f}\quad\rightarrow\quad f=5.0\text{cm}\quad\rightarrow\quad\boxed{r=10\text{cm}}$$

85. If total internal reflection fails at all, it fails for $\alpha\approx 90°$. Assume $\alpha=90°$ and use Snell's law to determine the maximum β.

$$n_2\sin\beta=n_1\sin\alpha=n_1\sin 90°=n_1\quad\rightarrow\quad\sin\beta=\frac{n_1}{n_2}$$

Snell's law can again be used to determine the angle δ for which light (if not totally internally reflected) would exit the top surface, using the relationship $\beta+\gamma=90°$ since they form two angles of a right triangle.

$$n_1\sin\delta=n_2\sin\gamma=n_2\sin(90°-\beta)=n_2\cos\beta\quad\rightarrow\quad\sin\delta=\frac{n_2}{n_1}\cos\beta$$

Using the trigonometric relationship $\cos\beta=\sqrt{1-\sin^2\beta}$ we can solve for the exiting angle in terms of the indices of refraction.

$$\sin\delta=\frac{n_2}{n_1}\sqrt{1-\sin^2\beta}=\frac{n_2}{n_1}\sqrt{1-\left(\frac{n_1}{n_2}\right)^2}$$

Insert the values for the indices ($n_1=1.00$ and $n_2=1.51$) to determine the sine of the exit angle.

$$\sin\delta=\frac{1.51}{1.00}\sqrt{1-\left(\frac{1.00}{1.51}\right)^2}=1.13$$

Since the sine function has a maximum value of 1, the light totally internally reflects at the glass–air interface for any incident angle of light.

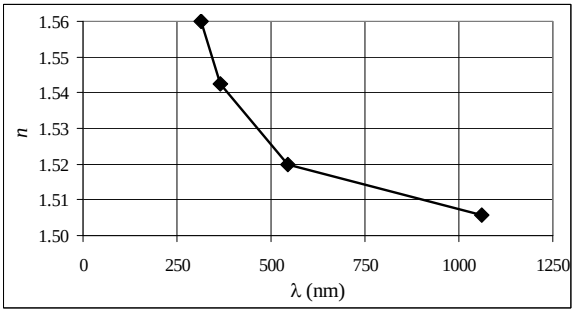
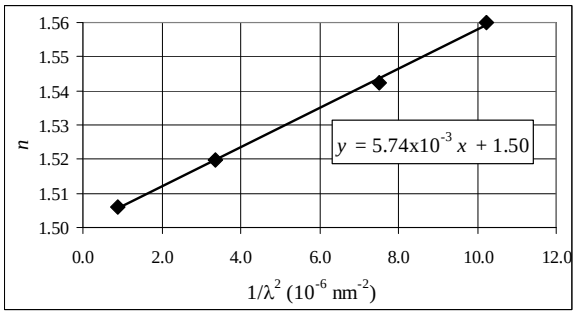
If the glass is immersed in water, then $n_1 = 1.33$ and $n_2 = 1.51$.

$$\sin\delta = \frac{1.51}{1.33}\sqrt{1-\left(\frac{1.33}{1.51}\right)^2} = 0.538 \quad \rightarrow \quad \delta = \sin^{-1} 0.538 = 32.5°$$

Light entering the glass from water at 90° can escape out the top at 32.5°, therefore total internal reflection only occurs for incident angles $\boxed{\leq 32.5°}$.

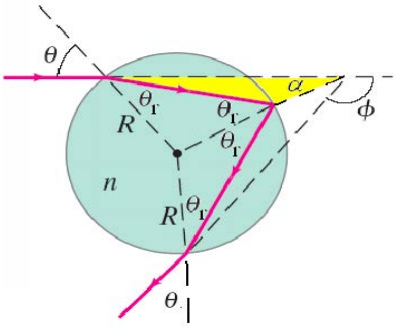
86. The path of the ray in the sphere forms an isosceles triangle with two radii. The two identical angles of the triangle are equal to the refracted angle. Since the incoming ray is horizontal, the third angle is the supplementary angle of the incident angle. We set the sum of these angles equal to 180° and solve for the ratio of the incident and refracted angles. Finally we use Snell's law in the small angle approximation to calculate the index of refraction.





$$2\theta_r + (180° - \theta) = 180° \quad \rightarrow \quad \theta = 2\theta_r$$

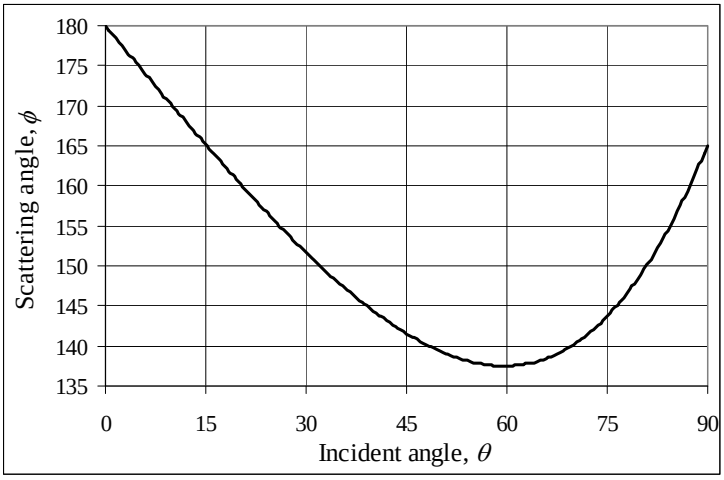
$$n_1 \sin\theta = n_2 \sin\theta_r \quad \rightarrow \quad \theta = n\theta_r = 2\theta_r \quad \rightarrow \quad \boxed{n = 2}$$



87. The first graph is a graph of n vs. λ. The second graph is a graph n vs. of $1/\lambda^2$. By fitting a line of the form $n = A + B/\lambda^2$, we have $A = 1.50$ and $B = \left(5.74\times10^{-3}\right)/10^{-6}\,\text{nm}^{-2} = \boxed{5740\,\text{nm}^2}$.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH32.XLS," on tab "Problem 32.87."

88. (*a*) As the light ray enters the water drop, its path changes by the difference between the incident and refracted angles. We use Snell's law to calculate the refracted angle. The light ray then reflects off the back surface of the droplet. At this surface its path changes by $180° - 2\theta_r$, as seen in the diagram. As the light exits the droplet it refracts again, changing its path by the difference between the incident and refracted angles. Summing these three angles gives the total path change.



$$\sin\theta = n\sin\theta_r \rightarrow \theta_r = \sin^{-1}\left(\frac{\sin\theta}{n}\right)$$

$$\phi = (\theta - \theta_r) + (180° - 2\theta_r) + (\theta - \theta_r) = 180° + 2\theta - 4\theta_r = \boxed{180° + 2\theta - 4\sin^{-1}\left(\frac{\sin\theta}{n}\right)}$$

(*b*) Here is the graph of ϕ vs θ. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH32.XLS," on tab "Problem 32.88."

(*c*) On the spreadsheet, the incident angles that give scattering angles from 138° to 140° are approximately $48.5° \le \theta \le 54.5°$ and $64.5° \le \theta \le 69.5°$. This is 11/90 of the possible incident angles, or about 12%.

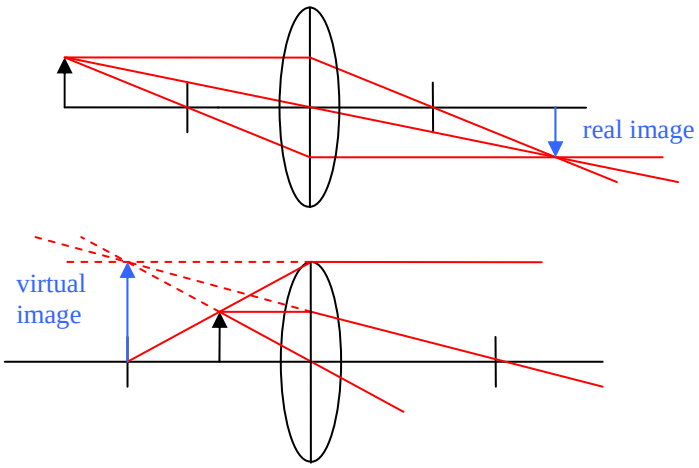
CHAPTER 33: Lenses and Optical Instruments



Responses to Questions

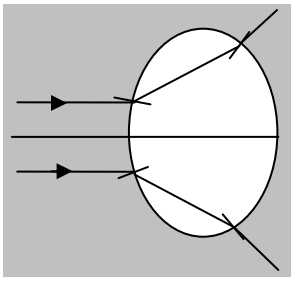
1. The film must be placed behind the lens at the focal length of the lens.

2. The lens moves farther away from the film. When the photographer moves closer to his subject, the object distance decreases. The focal length of the lens does not change, so the image distance must increase, by Eq. 33-2, $\frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i}$.

3. Yes. Diverging lenses, by definition, cause light rays to diverge and will not bring rays from a real object to a focal point as required to form a real image. However, if another optical element (for example, a converging lens) forms a virtual object for the diverging lens, it is possible for the diverging lens to form a real image.

4. A real image formed by a thin lens is on the opposite side of the lens as the object, and will always be inverted as shown in the top diagram. A virtual image is formed on the same side of the lens as the real object, and will be upright, as shown in the bottom diagram.

5. Yes. In the thin-lens equation, the variables for object distance and image distance can be interchanged and the formula remains the same.



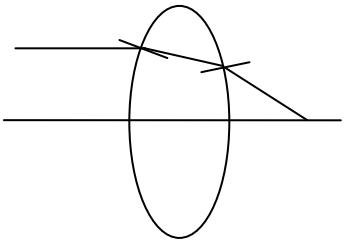
6. Yes, real images can be projected on a screen. No, virtual images cannot, because they are formed by diverging rays, which do not come to a focus on the screen. Both kinds of images can be photographed. The lenses in a camera are designed to focus either converging or diverging light rays down onto the film.

7. (*a*) Yes. The image moves farther from the lens.
(*b*) Yes. The image also gets larger.

8. The mirror equation and the lens equation are identical. According to the sign conventions, $d > 0$ indicates a real object or image and $d < 0$ indicates a virtual object or image, for both mirrors and lenses. But the positions of the objects and images are different for a mirror and a lens. For a mirror, a real object or image will be in front of the mirror and a virtual object or image will be behind the mirror. For a lens, a real image will be on the opposite side of the lens from a real object, and a virtual image will be on the same side of the lens as the real object.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9. No. The lens will be a diverging lens when placed in water because the index of refraction of the lens is less than the index of refraction of the medium surrounding it. Rays going from water to lens material will bend away from the normal instead of toward the normal, and rays going from the lens back to the water will bend towards the normal.

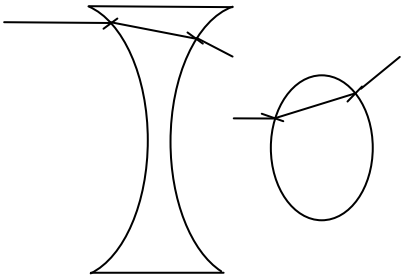


10. A virtual image created by a previous lens can serve as a virtual object for a second lens. If the previous lens creates an image behind the position of the second lens, that image will also serve as a virtual object for the second lens.

11. Assuming that the lens remains fixed and the screen is moved, the dog's head will have the greater magnification. The object distance for the head is less than the object distance for the tail, because the dog is facing the mirror. The image distance for the head will therefore be greater than the image distance for the tail. Magnification is the ratio of the image distance to the object distance, so will be greater for the head.

12. If the cat's nose is closer to the lens than the focal point and the tail is farther from the lens than the focal point, the image of the nose will be virtual and the image of the tail will be real. The virtual image of the front part of the cat will be spread out from the image of the nose to infinity on the same side of the lens as the cat. The real image of the back part of the cat will be spread out from the image of the tail to infinity on the opposite side of the lens.

13. The technique for determining the focal length of the diverging lens in Example 33-6 requires the combination of the two lenses together to project a real image of the sun onto a screen. The focal length of the lens combination can be measured. If the focal length of the converging lens is longer than the focal length of the diverging lens (the converging lens is weaker than the diverging lens), then the lens combination will be diverging, and will not form a real image of the sun. In this case the focal length of the combination of lenses cannot be measured, and the focal length of the diverging lens alone cannot be determined.



14. A double convex lens causes light rays to converge because the light bends towards the normal as it enters the lens and away from the normal as it exits the lens. The result, due to the curvature of the sides of the lens, is that the light bends towards the principal axis at both surfaces. The more strongly the sides of the lens are curved, the greater the bending, and the shorter the focal length.

15. Yes. The relative values of the index of refraction of the fluid and the index of refraction of the lens will determine the refraction of light as it passes from the fluid through the lens and back into the fluid. The amount of refraction of light determines the focal length of the lens, so the focal length will change if the lens is immersed in a fluid. No, the image formation of the spherical mirror is determined by reflection, not refraction, and is independent of the medium in which the mirror is immersed.

16. The lens material is air and the medium in which the lens is placed is water. Air has a lower index of refraction than water, so the light rays will bend away from the normal when entering the lens and towards the normal when leaving the lens.
    (*a*) A converging lens can be made by a shape that is thinner in the middle than it is at the edges.
    (*b*) A diverging lens will be thicker in the middle than it is at the edges.

17. If the object of the second lens (the image from the first lens) is exactly at the focal point, then a virtual image will be formed at infinity and can be viewed with a relaxed eye.

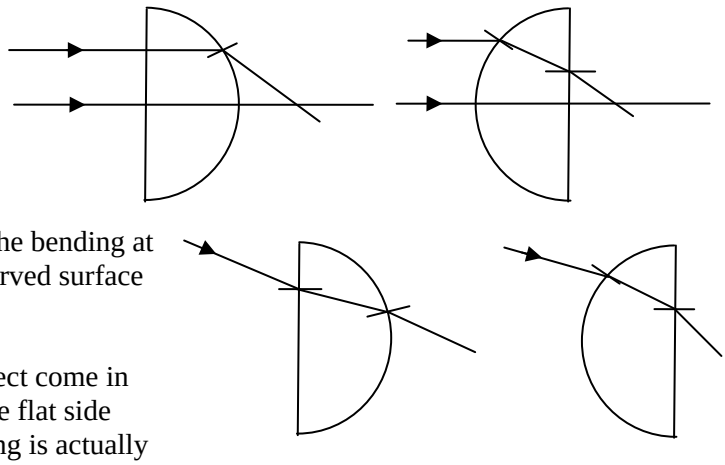
18. The corrective lenses will not work the same underwater as in air, and so the nearsighted person will probably not be able to see clearly underwater. The difference in the index of refraction of water and glass is much smaller than the difference in the indices for air and glass, so the lenses will not cause the incoming rays to diverge sufficiently.

Diverging lens

19. Nearsighted. Diverging lenses are used to correct nearsightedness and converging lenses are used to correct farsightedness. If the person's face appears narrower through the glasses, then the image of the face produced by the lenses is smaller than the face, virtual, and upright. Thus, the lenses must be diverging, and therefore the person is nearsighted.

20. All light entering the camera lens while the shutter is open contributes to a single picture. If the camera is moved while the shutter is open, the position of the image on the film moves. The new image position overlaps the previous image position, causing a blurry final image. With the eye, new images are continuously being formed by the nervous system, so images do not "build up" on the retina and overlap with each other.

21. Squinting limits the off-axis rays that enter the eye and results in an image that is formed primarily by the center part of the lens, reducing spherical aberration and spreading of the image.



22. The image formed on the retina is inverted. The human brain then processes the image so that we interpret the world we see correctly.

23. Both reading glasses and magnifiers are converging lenses used to produce magnified images. A magnifier, generally a short focal length lens, is typically used by adjusting the distance between the lens and the object so that the object is exactly at or just inside the focal point. An object exactly at the focal point results in an image that is at infinity and can be viewed with a relaxed eye. If the lens is adjusted so that it focuses the image at the eye's near point, the magnification is slightly greater. The lenses in reading glasses typically are a fixed distance from the eye. These lenses cause the rays from a nearby object to converge somewhat before they reach the eye, allowing the eye to focus on an object that is inside the near point. The focal length of the lens needed for reading glasses will depend on the individual eye. The object does not have to be inside the focal point of the lens. For both reading glasses and magnifiers, the lenses allow the eye to focus on an object closer than the near point.

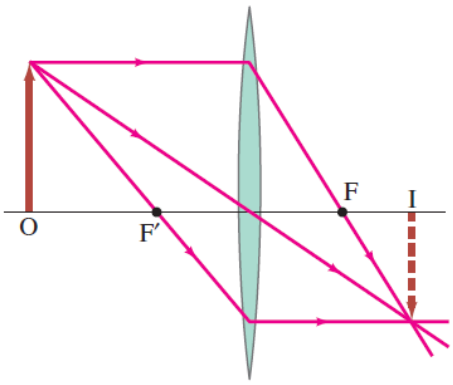
24. The relationship between d_i and d_o for a given lens of focal length f is given by Eq. 33-2, $\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}$. The focal length is fixed for a camera lens, so if the lens focuses on a closer object, d_o decreases and therefore d_i must increase. An increase in d_i means that the lens must be farther from the film.

25. The curved surface should face the object. If the flat surface faces the object and the rays come in parallel to the optical axis, then no bending will occur at the first surface and all the bending will occur at the second surface. Bending at the two surfaces will clearly not be equal in this case. The bending at the two surfaces may be equal if the curved surface faces the object.



If the parallel rays from the distant object come in above or below the optical axis with the flat side towards the object, then the first bending is actually away from the axis. In this case also, bending at both surfaces can be equal if the curved side of the lens faces the object.

26. For both converging and diverging lenses, the focal point for violet light is closer to the lens than the focal point for red light. The index of refraction for violet light is slightly greater than for red light for glass, so the violet light bends more, resulting in a smaller magnitude focal length.

Solutions to Problems

1. (*a*) From the ray diagram, the object distance is about 480 cm.

(*b*) We find the object distance from Eq. 33-2.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow$$

$$d_o=\frac{fd_i}{d_i-f}=\frac{(215\,\text{mm})(373\,\text{mm})}{373\,\text{mm}-215\,\text{mm}}=\boxed{508\,\text{mm}}$$

NOTE: In the first printing of the textbook, a different set of values was given: $f=75.0\,\text{mm}$ and $d_i=88.0\,\text{mm}$. Using that set of values gives the same object distance as above. But the ray diagram would be much more elongated, with the object distance almost 7 times the focal length.

2. (*a*) To form a real image from parallel rays requires a converging lens.

(*b*) We find the power of the lens from Eqs. 33-1 and 33-2.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}=P=\frac{1}{\infty}+\frac{1}{0.185\,\text{m}}=\boxed{5.41\,\text{D}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

3. (*a*) The power of the lens is given by Eq. 33.1

$$P = \frac{1}{f} = \frac{1}{0.235\,\text{m}} = \boxed{4.26\,\text{D}}$$

This lens is converging.

(*b*) We find the focal length of the lens from Eq. 33.1

$$P = \frac{1}{f} \quad \rightarrow \quad f = \frac{1}{D} = -\frac{1}{6.75\,\text{D}} = \boxed{-0.148\,\text{m}}$$

This lens is diverging.

4. To form a real image from a real object requires a converging lens. We find the focal length of the lens from Eq. 33-2.

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = \frac{d_\text{o} d_\text{i}}{d_\text{o} + d_\text{i}} = \frac{(1.85\,\text{m})(0.483\,\text{m})}{1.85\,\text{m} + 0.483\,\text{m}} = \boxed{0.383\,\text{m}}$$

Because $d_\text{i} > 0$, the image is real.

5. (*a*) We find the image distance from Eq. 33-2.

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad d_\text{i} = \frac{d_\text{o} f}{d_\text{o} - f} = \frac{(10.0\,\text{m})(0.105\,\text{m})}{10.0\,\text{m} - 0.105\,\text{m}} = 0.106\,\text{m} = \boxed{106\,\text{mm}}$$

(*b*) Use the same general calculation.

$$d_\text{i} = \frac{d_\text{o} f}{d_\text{o} - f} = \frac{(3.0\,\text{m})(0.105\,\text{m})}{3.0\,\text{m} - 0.105\,\text{m}} = 0.109\,\text{m} = \boxed{109\,\text{mm}}$$

(*c*) Use the same general calculation.

$$d_\text{i} = \frac{d_\text{o} f}{d_\text{o} - f} = \frac{(1.0\,\text{m})(0.105\,\text{m})}{1.0\,\text{m} - 0.105\,\text{m}} = 0.117\,\text{m} = \boxed{117\,\text{mm}}$$

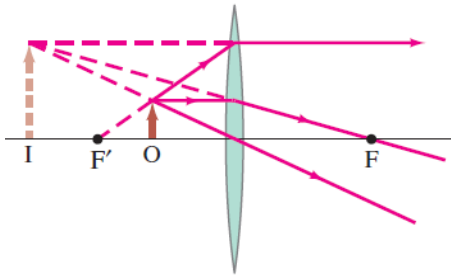
(*d*) We find the smallest object distance from the maximum image distance.

$$\frac{1}{d_{\text{o}_\text{min}}} + \frac{1}{d_{\text{i}_\text{max}}} = \frac{1}{f} \quad \rightarrow \quad d_{\text{o}_\text{min}} = \frac{d_{\text{i}_\text{max}} f}{d_{\text{i}_\text{max}} - f} = \frac{(132\,\text{mm})(105\,\text{mm})}{132\,\text{mm} - 105\,\text{mm}} = 513\,\text{mm} = \boxed{0.513\,\text{m}}$$

6. (*a*) We locate the image using Eq. 33-2.

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad d_\text{i} = \frac{d_\text{o} f}{d_\text{o} - f} = \frac{(18\,\text{cm})(28\,\text{cm})}{18\,\text{cm} - 28\,\text{cm}} = -50.4\,\text{cm} \approx -50\,\text{cm}$$

The negative sign means the image is 50 cm behind the lens (virtual).



(*b*) We find the magnification from Eq. 33-3.

$$m = -\frac{d_\text{i}}{d_\text{o}} = -\frac{(-50.4\,\text{cm})}{(18\,\text{cm})} = \boxed{+2.8}$$

7. (*a*) The image should be upright for reading. The image will be virtual, upright, and magnified.

(*b*) To form a virtual, upright magnified image requires a converging lens.

(*c*) We find the image distance, then the focal length, and then the power of the lens. The object distance is given.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$m = -\frac{d_i}{d_o} \quad \rightarrow \quad d_i = -md_o$$

$$P = \frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} = \frac{d_i + d_o}{d_o d_i} = \frac{-md_o + d_o}{d_o(-md_o)} = \frac{m-1}{md_o} = \frac{2.5-1}{(2.5)(0.090\,\text{m})} = \boxed{6.7\,\text{D}}$$

8. Use Eqs. 33-1 and 33-2 to find the image distance, and Eq. 33-3 to find the image height.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} = P \quad \rightarrow \quad d_i = \frac{d_o}{Pd_o - 1} = \frac{(0.125\,\text{m})}{(-8.00\,\text{D})(0.125\,\text{m}) - 1} = -0.0625\,\text{m} = \boxed{-6.25\,\text{cm}}$$

Since the image distance is negative, the image is virtual and behind the lens.

$$m = \frac{h_i}{h_o} = -\frac{d_i}{d_o} \quad \rightarrow \quad h_i = -\frac{d_i}{d_o}h_o = -\frac{(-6.25\,\text{cm})}{12.5\,\text{cm}}(1.00\,\text{mm}) = \boxed{0.500\,\text{mm}\,(\text{upright})}$$

9. First, find the original image distance from Eqs. 33-1 and 33-2.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} = P \quad \rightarrow \quad d_i = \frac{d_o}{Pd_o - 1} = \frac{(1.50\,\text{m})}{(8.00\,\text{D})(1.50\,\text{m}) - 1} = 0.1364\,\text{m}$$

(*a*) With $d_o = 0.60\,\text{m}$, find the new image distance.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} = P \quad \rightarrow \quad d_i = \frac{d_o}{Pd_o - 1} = \frac{(0.60\,\text{m})}{(8.00\,\text{D})(0.60\,\text{m}) - 1} = 0.1579\,\text{m}$$

Thus the image has moved $0.1579\,\text{m} - 0.1364\,\text{m} = 0.0215\,\text{m} \approx \boxed{0.02\,\text{m}}$ away from the lens.

(*b*) With $d_o = 2.40\,\text{m}$, find the new image distance.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} = P \quad \rightarrow \quad d_i = \frac{d_o}{Pd_o - 1} = \frac{(2.40\,\text{m})}{(8.00\,\text{D})(2.40\,\text{m}) - 1} = 0.1319\,\text{m}$$

The image has moved $0.1319\,\text{m} - 0.1364\,\text{m} = -0.0045\,\text{m} \approx \boxed{0.004\,\text{m}}$ toward the lens.

10. (*a*) If the image is real, the focal length must be positive, the image distance must be positive, and the magnification is negative. Thus $d_i = 2.50d_o$. Use Eq. 33-2.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{d_o} + \frac{1}{2.50d_o} = \frac{1}{f} \quad \rightarrow \quad d_o = \left(\frac{3.50}{2.50}\right)f = \left(\frac{3.50}{2.50}\right)(50.0\,\text{mm}) = \boxed{70.0\,\text{mm}}$$

(*b*) If the image is magnified, the lens must have a positive focal length, because negative lenses always form reduced images. Since the image is virtual the magnification is positive. Thus $d_i = -2.50d_o$. Again use Eq. 33-2.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{d_o} - \frac{1}{2.5d_o} = \frac{1}{f} \quad \rightarrow \quad d_o = \left(\frac{1.50}{2.50}\right)f = \left(\frac{1.50}{2.50}\right)(50.0\,\text{mm}) = \boxed{30.0\,\text{mm}}$$

11. From Eq. 33-3, $|h_i| = |h_o|$ when $d_i = d_o$. So find d_o from Eq. 33-2.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{d_o} + \frac{1}{d_o} = \frac{1}{f} \quad \rightarrow \quad d_o = 2f = \boxed{50\,\text{cm}}$$

12. (*a*) Use Eqs. 33-2 and 33-3.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} \quad \rightarrow \quad d_i = \frac{d_o f}{d_o - f} = \frac{(1.30\,\text{m})(0.135\,\text{m})}{1.30\,\text{m} - 0.135\,\text{m}} = 0.1506\,\text{m} \approx \boxed{151\,\text{mm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

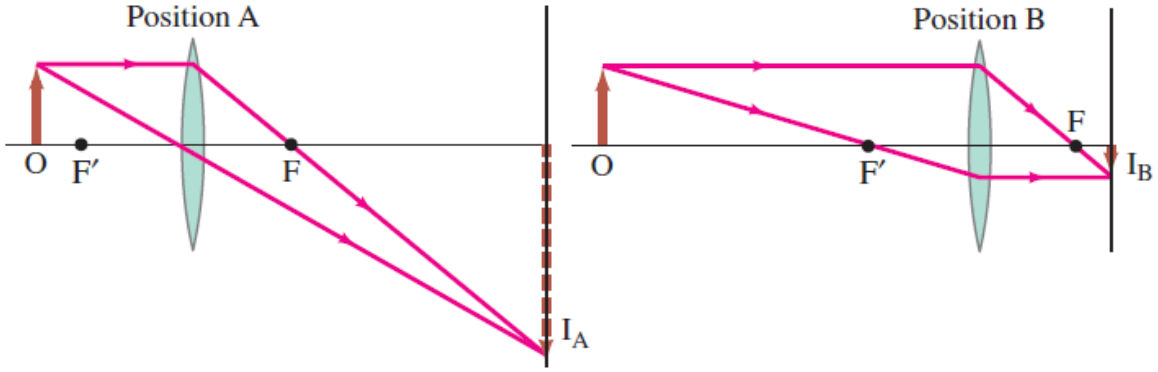
$$m = \frac{h_i}{h_o} = -\frac{d_i}{d_o} \quad \rightarrow \quad h_i = -\frac{d_i}{d_o} h_o = -\frac{0.1506\,\text{m}}{1.30\,\text{m}}(2.80\,\text{cm}) = \boxed{-0.324\,\text{m}}$$

The image is behind the lens a distance of 151 mm, is real, and is inverted.

(*b*) Again use Eqs. 33-2 and 33-3.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} \quad \rightarrow \quad d_i = \frac{d_o f}{d_o - f} = \frac{(1.30\,\text{m})(-0.135\,\text{m})}{1.30\,\text{m} - (-0.135\,\text{m})} = -0.1223\,\text{m} \approx \boxed{-122\,\text{mm}}$$

$$m = \frac{h_i}{h_o} = -\frac{d_i}{d_o} \quad \rightarrow \quad h_i = -\frac{d_i}{d_o} h_o = -\frac{(-0.1223\,\text{m})}{1.30\,\text{m}}(2.80\,\text{cm}) = \boxed{0.263\,\text{m}}$$



The image is in front of the lens a distance of 122 mm, is virtual, and is upright.

13. The sum of the object and image distances must be the distance between object and screen, which we label as d_T. We solve this relationship for the image distance, and use that expression in Eq. 33-2 in order to find the object distance.

$$d_o + d_i = d_T \quad \rightarrow \quad d_i = d_T - d_o \;\; ; \;\; \frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{d_o} + \frac{1}{(d_T - d_o)} = \frac{1}{f} \quad \rightarrow \quad d_o^2 - d_T d_o + f d_T = 0 \quad \rightarrow$$

$$d_o = \frac{d_T \pm \sqrt{d_T^2 - 4 f d_T}}{2} = \frac{(86.0\,\text{cm}) \pm \sqrt{(86.0\,\text{cm})^2 - 4(16.0\,\text{cm})(86.0\,\text{cm})}}{2} = \boxed{21.3\text{cm, } 64.7\,\text{cm}}$$

Note that to have real values for d_o, we must in general have $d_T^2 - 4 f d_T > 0 \quad \rightarrow \quad d_T > 4f$.

14. For a real image both the object distance and image distances are positive, and so the magnification is negative. Use Eqs. 33-2 and 33-3 to find the object and image distances. Since they are on opposite sides of the lens, the distance between them is their sum.

$$m = \frac{-d_i}{d_o} \quad \rightarrow \quad d_i = -m d_o = 2.95 d_o$$

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{d_o} + \frac{1}{2.95 d_o} = \frac{1}{f} \quad \rightarrow \quad d_o = \left(\frac{3.95}{2.95}\right) f = \left(\frac{3.95}{2.95}\right)(85\,\text{cm}) = 113.8\,\text{cm}$$

$$d_i = 2.95 d_o = 2.95(113.8\,\text{cm}) = 335.7\,\text{cm}$$

$$d_o + d_i = 113.8\,\text{cm} + 335.7\,\text{cm} = 449.5\,\text{cm} \approx \boxed{450\,\text{cm}}$$

15. (*a*) Use Eq. 33-2 to write an expression for the image distance in terms of the object distance and focal length. We then use Eq. 33-3 to write an expression for the magnification.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} \quad \rightarrow \quad d_i = \frac{d_o f}{d_o - f} \;\; ; \;\; m = -\frac{d_i}{d_o} = -\frac{f}{d_o - f}$$

These expressions show that when $d_o > f$, the image distance is positive, producing a real image, and the magnification is negative, which gives an inverted image.

(*b*) From the above equations, when $d_o < f$, the image distance is negative, producing a virtual image, and the magnification is positive, which gives an upright image.

(*c*) We set $-d_o = f$ and calculate the limiting image distance and magnification.

$$d_i = \frac{(-f)f}{-f-f} = \frac{f}{2} \qquad m = -\frac{d_i}{d_o} = -\frac{f}{-f-f} = \frac{1}{2}$$

We also take the limit of large negative object distance.

$$d_i = \frac{(-\infty)f}{-\infty - f} = f \qquad m = -\frac{d_i}{d_o} = -\frac{f}{-\infty - f} = 0$$

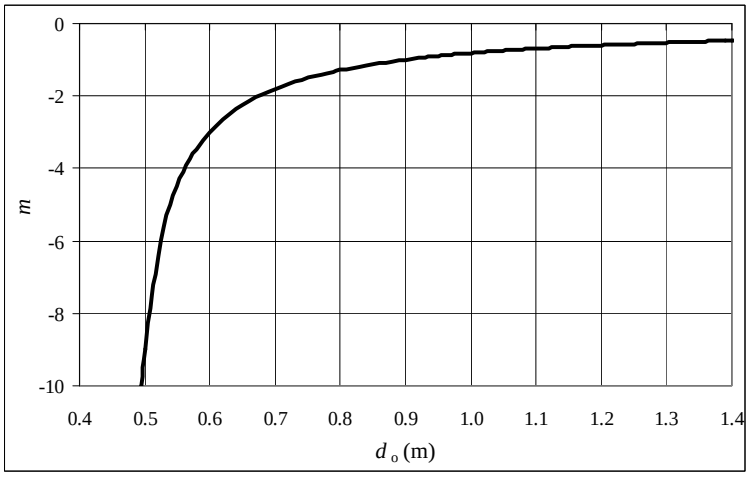
From these limiting cases, we see that when $-d_o > f$, the image is real and upright with $\frac{1}{2}f < d_i < f$ and $0 < m < \frac{1}{2}$.

(*d*) We take the limiting condition $d_o \to 0$, and determine the resulting image distance and magnification.

$$d_i = \frac{(0)f}{0-f} = 0 \qquad m = -\frac{d_i}{d_o} = -\frac{f}{0-f} = 1$$

From this limit and that found in part (*c*), we see that when $0 < -d_o < f$, the image is real and upright, with $0 < d_i < \frac{1}{2}f$ and $\frac{1}{2} < m < 1$.

16. (*a*) We use the magnification equation, Eq. 33-3, to write the image distance in terms of the magnification and object distance. We then replace the image distance in the mirror equation, Eq. 32-2, and solve for the magnification in terms of the object distance and the focal length.



$$m = -d_i/d_o \quad \to \quad d_i = -md_o$$

$$\frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} \quad \to$$

$$\frac{1}{f} = \frac{1}{d_o} + \frac{1}{-md_o} \quad \to$$

$$\boxed{m = \frac{f}{f - d_o}}$$

(*b*) We set $f = 0.45$ m and draw a graph of the magnification as a function of the object distance. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH33.XLS," on tab "Problem 33.16b."

(*c*) The image and object will have the same lateral size when the magnification is equal to negative one. Setting the magnification equal to negative one, we solve the equation found in part (a) for the object distance.

$$m = \frac{f}{f - d_o} = -1 \quad \to \quad d_o = 2f = \boxed{0.90\,\text{m}}$$

(*d*) From the graph we see that for the image to be much larger than the object, the object should be placed at a point just beyond the focal point.

17. Find the object distance from Eq. 33-2.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad \frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad d_o=\frac{fd_i}{d_i-f}=\frac{(0.105\,\text{m})(6.50\,\text{m})}{6.50\,\text{m}-0.105\,\text{m}}=\boxed{0.107\,\text{m}}$$

Find the size of the image from Eq. 33-3.

$$m=\frac{h_i}{h_o}=-\frac{d_i}{d_o} \quad \rightarrow \quad |h_i|=\frac{d_i}{d_o}h_o=\frac{6.50\,\text{m}}{0.107\,\text{m}}(36\,\text{mm})=2187\,\text{mm}\approx\boxed{2.2\,\text{m}}$$

18. (*a*) Use Eq. 33-2 with $d_o+d_i=d_T \quad \rightarrow \quad d_i=d_T-d_o$.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{d_o}+\frac{1}{(d_T-d_o)}=\frac{1}{f} \quad \rightarrow \quad d_o^2-d_Td_o+fd_T=0 \quad \rightarrow \quad d_o=\frac{d_T\pm\sqrt{d_T^2-4fd_T}}{2}$$

There are only real solutions for d_o if $d_T^2-4fd_T>0 \quad \rightarrow \quad d_T>4f$. If that condition is met, then there will be two locations for the lens, at distances $d_o=\frac{1}{2}\left(d_T\pm\sqrt{d_T^2-4fd_T}\right)$ from the object, that will form sharp images on the screen.

(*b*) If $d_T<4f$, then Eq. 33-2 cannot be solved for real values of d_o or d_i.

(*c*) If $d_T>4f$, the lens locations relative to the object are given by $d_{o1}=\frac{1}{2}\left(d_T+\sqrt{d_T^2-4fd_T}\right)$ and $d_{o2}=\frac{1}{2}\left(d_T-\sqrt{d_T^2-4fd_T}\right)$.

$$\Delta d=d_{o1}-d_{o2}=\tfrac{1}{2}\left(d_T+\sqrt{d_T^2-4fd_T}\right)-\tfrac{1}{2}\left(d_T-\sqrt{d_T^2-4fd_T}\right)=\boxed{\sqrt{d_T^2-4fd_T}}$$

Find the ratio of image sizes using Eq. 33-3.

$$\frac{h_{i2}}{h_{i1}}=\frac{-h_o\dfrac{d_{i2}}{d_{o2}}}{-h_o\dfrac{d_{i1}}{d_{o1}}}=\frac{d_{i2}}{d_{o2}}\frac{d_{o1}}{d_{i1}}=\frac{d_T-d_{o2}}{d_{o2}}\frac{d_{o1}}{d_T-d_{o1}}$$

$$=\left[\frac{d_T-\frac{1}{2}\left(d_T-\sqrt{d_T^2-4fd_T}\right)}{\frac{1}{2}\left(d_T-\sqrt{d_T^2-4fd_T}\right)}\right]\left[\frac{\frac{1}{2}\left(d_T+\sqrt{d_T^2-4fd_T}\right)}{d_T-\frac{1}{2}\left(d_T+\sqrt{d_T^2-4fd_T}\right)}\right]=\boxed{\left(\frac{d_T+\sqrt{d_T^2-4fd_T}}{d_T-\sqrt{d_T^2-4fd_T}}\right)^2}$$

19. (*a*) With the definitions as given in the problem, $x=d_o-f \quad \rightarrow \quad d_o=x+f$ and $x'=d_i-f \quad \rightarrow \quad d_i=x'+f$. Use Eq. 33-2.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{x+f}+\frac{1}{x'+f}=\frac{1}{f} \quad \rightarrow \quad \frac{(x'+f)+(x+f)}{(x+f)(x'+f)}=\frac{1}{f} \quad \rightarrow$$

$$(2f+x+x')f=(x+f)(x'+f) \quad \rightarrow \quad 2f^2+xf+x'f=x'x+xf+fx'+f^2 \quad \rightarrow \quad \boxed{f^2=x'x}$$

(*b*) Use Eq. 33-2.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad d_i=\frac{d_of}{d_o-f}=\frac{(48.0\,\text{cm})(38.0\,\text{cm})}{48.0\,\text{cm}-38.0\,\text{cm}}=\boxed{182\,\text{cm}}$$

(*c*) Use the Newtonian form.

$$xx'=f^2 \quad \rightarrow \quad x'=\frac{f^2}{x}=\frac{(38.0\,\text{cm})^2}{(48.0\,\text{cm}-38.0\,\text{cm})}=144.2\,\text{cm}$$

$$d_i=x'+f=144.2\,\text{cm}+38.0\,\text{cm}=\boxed{182\,\text{cm}}$$

20. The first lens is the converging lens. An object at infinity will form an image at the focal point of the converging lens, by Eq. 33-2.

$$\frac{1}{d_{o1}}+\frac{1}{d_{i1}}=\frac{1}{f_1}=\frac{1}{\infty}+\frac{1}{d_{i1}} \quad \rightarrow \quad d_{i1}=f_1=20.0\,\text{cm}$$

This image is the object for the second lens. Since this image is behind the second lens, the object distance for the second lens is negative, and so $d_{o2}=-6.0\,\text{cm}$. Again use Eq. 33-2.

$$\frac{1}{d_{o2}}+\frac{1}{d_{i2}}=\frac{1}{f_2} \quad \rightarrow \quad d_{i2}=\frac{d_{o2}f_2}{d_{o2}-f_2}=\frac{(-6.0\,\text{cm})(-33.5\,\text{cm})}{(-6.0\,\text{cm})-(-33.5\,\text{cm})}=7.3\,\text{cm}$$

Thus the final image is real, 7.3 cm beyond the second lens.

21. Find the image formed by the first lens, using Eq. 33-2.

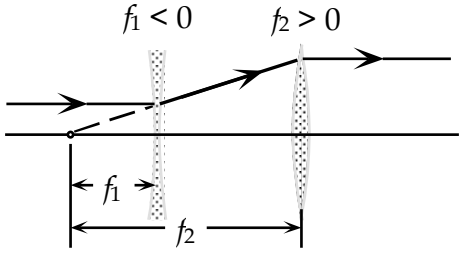
$$\frac{1}{d_{o1}}+\frac{1}{d_{i1}}=\frac{1}{f_1} \quad \rightarrow \quad d_{i1}=\frac{d_{o1}f_1}{d_{o1}-f_1}=\frac{(35.0\,\text{cm})(25.0\,\text{cm})}{(35.0\,\text{cm})-(25.0\,\text{cm})}=87.5\,\text{cm}$$

This image is the object for the second lens. Because it is beyond the second lens, it has a negative object distance.

$$d_{o2}=16.5\,\text{cm}-87.5\,\text{cm}=-71.0\,\text{cm}$$

Find the image formed by the second lens, again using Eq. 33-2.

$$\frac{1}{d_{o2}}+\frac{1}{d_{i2}}=\frac{1}{f_2} \quad \rightarrow \quad d_{i2}=\frac{d_{o2}f_2}{d_{o2}-f_2}=\frac{(-71.0\,\text{cm})(25.0\,\text{cm})}{(-71.0\,\text{cm})-(25.0\,\text{cm})}=18.5\,\text{cm}$$



Thus the final image is real, 18.5 cm beyond second lens.

The total magnification is the product of the magnifications for the two lenses:

$$m=m_1m_2=\left(-\frac{d_{i1}}{d_{o1}}\right)\left(-\frac{d_{i2}}{d_{o2}}\right)=\frac{d_{i1}d_{i2}}{d_{o1}d_{o2}}$$

$$=\frac{(+87.5\,\text{cm})(+18.5\,\text{cm})}{(+35.0\,\text{cm})(-71.0\,\text{cm})}=\boxed{-0.651\times(\text{inverted})}$$

22. From the ray diagram, the image from the first lens is a virtual image at the focal point of the first lens. This is a real object for the second lens. Since the light is parallel after leaving the second lens, the object for the second lens must be at its focal point. Let the separation of the lenses be ℓ. Note that the focal length of the diverging lens is negative.

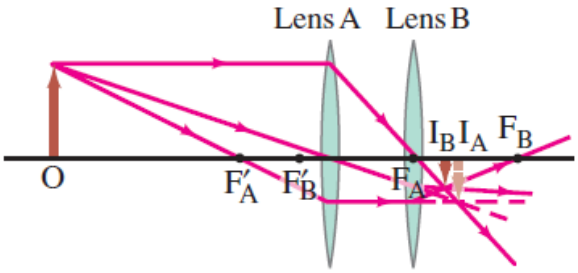
$$|f_1|+\ell=f_2 \quad \rightarrow$$

$$|f_1|=f_2-\ell=34.0\,\text{cm}-24.0\,\text{cm}=10.0\,\text{cm} \quad \rightarrow$$

$$f_1=\boxed{-10.0\,\text{cm}}$$

23. (*a*) The first image is formed as in Example 33-5, and so $d_{iA}=30.0\,\text{cm}$. This image becomes the object for the lens B, at a distance $d_{oB}=20.0\,\text{cm}-30.0\,\text{cm}=-10.0\,\text{cm}$. This is a virtual object since it is behind lens N. Use Eq. 33-2 to find the image formed by lens B, which is the final image.

$$\frac{1}{d_{oB}}+\frac{1}{d_{iB}}=\frac{1}{f_B} \quad \rightarrow \quad d_{iB}=\frac{d_{oB}f_B}{d_{oB}-f_B}=\frac{(-10.0\,\text{cm})(25.0\,\text{cm})}{-10.0\,\text{cm}-25.0\,\text{cm}}=7.14\,\text{cm}$$



So the final image is 7.14 cm beyond lens B.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The total magnification is the product of the magnifications for the two lenses:

$$m = m_1 m_2 = \left(-\frac{d_{iA}}{d_{oA}}\right)\left(-\frac{d_{iB}}{d_{oB}}\right) = \frac{d_{iA}d_{iB}}{d_{oA}d_{oB}} = \frac{(30.0\,\text{cm})(7.14\,\text{cm})}{(60.0\,\text{cm})(-10.0\,\text{cm})} = \boxed{-0.357}$$

(*c*) See the ray diagram here.

24. (*a*) Find the image formed by the converging lens, using Eq. 33-2.

$$\frac{1}{d_{o1}} + \frac{1}{d_{i1}} = \frac{1}{f_1} \quad \rightarrow \quad d_{i1} = \frac{d_{o1}f_1}{d_{o1} - f_1} = \frac{(33\,\text{cm})(18\,\text{cm})}{(33\,\text{cm}) - (18\,\text{cm})} = 39.6\,\text{cm}$$

This image is the object for the second lens. The image is to the right of the second lens, and so is virtual. Use that image to find the final image.

$$d_{o2} = 12\,\text{cm} - 39.6\,\text{cm} = -27.6\,\text{cm} \;;\; \frac{1}{d_{o2}} + \frac{1}{d_{i2}} = \frac{1}{f_2} \quad \rightarrow$$

$$d_{i2} = \frac{d_{o2}f_2}{d_{o2} - f_2} = \frac{(-27.6\,\text{cm})(-14\,\text{cm})}{(-27.6\,\text{cm}) - (-14\,\text{cm})} = -28.4\,\text{cm}$$

So the final image is 28 cm to the left of the diverging lens, or 16 cm to the left of the converging lens.

(*b*) The initial image is unchanged. With the change in the distance between the lenses, the image distance for the second lens has changed.

$$d_{o2} = 38\,\text{cm} - 39.6\,\text{cm} = -1.6\,\text{cm} \;;\; \frac{1}{d_{o2}} + \frac{1}{d_{i2}} = \frac{1}{f_2} \quad \rightarrow$$

$$d_{i2} = \frac{d_{o2}f_2}{d_{o2} - f_2} = \frac{(-1.6\,\text{cm})(-14\,\text{cm})}{(-1.6\,\text{cm}) - (-14\,\text{cm})} = 1.8\,\text{cm}$$

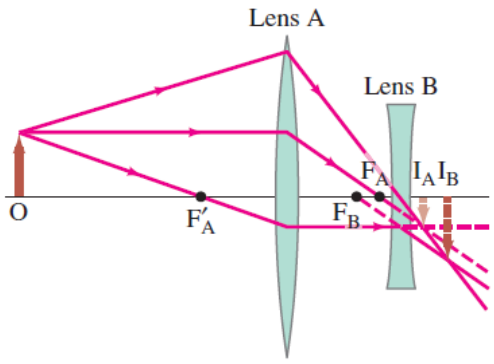
Now the final image is 1.8 cm to the right of the diverging lens.

25. (*a*) The first lens is the converging lens. Find the image formed by the first lens.

$$\frac{1}{d_{o1}} + \frac{1}{d_{i1}} = \frac{1}{f_1} \quad \rightarrow \quad d_{i1} = \frac{d_{o1}f_1}{d_{o1} - f_1} = \frac{(60.0\,\text{cm})(20.0\,\text{cm})}{(60.0\,\text{cm}) - (20.0\,\text{cm})} = 30.0\,\text{cm}$$

This image is the object for the second lens. Since this image is behind the second lens, the object distance for the second lens is negative, and so $d_{o2} = 25.0\,\text{cm} - 30.0\,\text{cm} = -5.0\,\text{cm}$. Use Eq. 33-2.

$$\frac{1}{d_{o2}} + \frac{1}{d_{i2}} = \frac{1}{f_2} \quad \rightarrow \quad d_{i2} = \frac{d_{o2}f_2}{d_{o2} - f_2} = \frac{(-5.0\,\text{cm})(-10.0\,\text{cm})}{(-5.0\,\text{cm}) - (-10.0\,\text{cm})} = 10\,\text{cm}$$



Thus the final image is real, 10 cm beyond the second lens. The distance has two significant figures.

(*b*) The total magnification is the product of the magnifications for the two lenses:

$$m = m_1 m_2 = \left(-\frac{d_{i1}}{d_{o1}}\right)\left(-\frac{d_{i2}}{d_{o2}}\right) = \frac{d_{i1}d_{i2}}{d_{o1}d_{o2}} = \frac{(30.0\,\text{cm})(10.0\,\text{cm})}{(60.0\,\text{cm})(-5.0\,\text{cm})} = \boxed{-1.0\times}$$

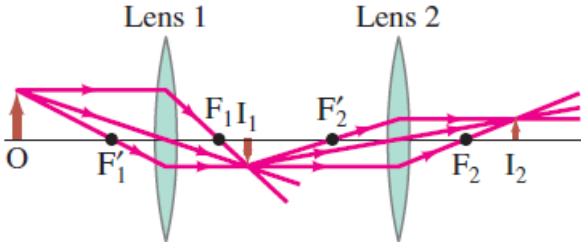
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) See the diagram here.

26. We find the focal length of the combination by finding the image distance for an object very far away. For the converging lens, we have the following from Eq. 33-2.

$$\frac{1}{d_{o1}}+\frac{1}{d_{i1}}=\frac{1}{f_C}=\frac{1}{\infty}+\frac{1}{d_{i1}} \quad \rightarrow \quad d_{i1}=f_C$$

The first image is the object for the second lens. Since the first image is real, the second object distance is negative. We also assume that the lenses are thin, and so $d_{o2}=-d_{i1}=-f_C$.



For the second diverging lens, we have the following from Eq. 33-2.

$$\frac{1}{d_{o2}}+\frac{1}{d_{i2}}=\frac{1}{f_D}=-\frac{1}{f_C}+\frac{1}{d_{i2}}$$

Since the original object was at infinity, the second image must be at the focal point of the combination, and so $d_{i2}=f_T$.

$$\frac{1}{f_D}=-\frac{1}{f_C}+\frac{1}{d_{i2}}=-\frac{1}{f_C}+\frac{1}{f_T}$$

27. (*a*) We see that the image is real and upright. We estimate that it is 30 cm beyond the second lens, and that the final image height is half the original object height.

(*b*) Find the image formed by the first lens, using Eq. 33-2.

$$\frac{1}{d_{o1}}+\frac{1}{d_{i1}}=\frac{1}{f_1} \quad \rightarrow$$

$$d_{i1}=\frac{d_{o1}f_1}{d_{o1}-f_1}=\frac{(36\text{cm})(13\text{cm})}{(36\text{cm})-(13\text{cm})}=20.35\text{cm}$$

This image is the object for the second lens. Because it is between the lenses, it has a positive object distance.

$$d_{o2}=56\text{cm}-20.35\text{cm}=35.65\text{cm}$$

Find the image formed by the second lens, again using Eq. 33-2.

$$\frac{1}{d_{o2}}+\frac{1}{d_{i2}}=\frac{1}{f_2} \quad \rightarrow \quad d_{i2}=\frac{d_{o2}f_2}{d_{o2}-f_2}=\frac{(35.65\text{cm})(16\text{cm})}{(35.65\text{cm})-(16\text{cm})}=29.25\text{cm}$$

Thus the final image is real, 29 cm beyond the second lens.

The total magnification is the product of the magnifications for the two lenses:

$$m=m_1m_2=\left(-\frac{d_{i1}}{d_{o1}}\right)\left(-\frac{d_{i2}}{d_{o2}}\right)=\frac{(20.35\text{cm})(29.25\text{cm})}{(36\text{cm})(35.65\text{cm})}=0.46\times$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

28. Use Eq. 33-4, the lensmaker's equation.

$$\frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) \rightarrow$$

$$f = \frac{1}{(n-1)}\left(\frac{R_1 R_2}{R_1 + R_2}\right) = \frac{1}{(1.58-1)}\left(\frac{(-33.4\,\text{cm})(-28.8\,\text{cm})}{(-33.4\,\text{cm}) + (-28.8\,\text{cm})}\right) = -26.66\,\text{cm} \approx \boxed{-27\,\text{cm}}$$

29. Find the index from Eq. 33-4, the lensmaker's equation.

$$\frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) \rightarrow n = 1 + \frac{1}{f}\left(\frac{R_1 R_2}{R_1 + R_2}\right) = 1 + \left(\frac{1}{28.9\,\text{cm}}\right)\left(\tfrac{1}{2}(31.4\,\text{cm})\right) = \boxed{1.54}$$

30. With the surfaces reversed, we have $R_1 = -46.2\,\text{cm}$ and $R_2 = +22.4\,\text{cm}$. Use Eq. 33-4 to find the focal length.

$$\frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) \rightarrow$$

$$f = \frac{1}{(n-1)}\left(\frac{R_1 R_2}{R_1 + R_2}\right) = \frac{1}{(1.50-1)}\left(\frac{(-46.2\,\text{cm})(+22.4\,\text{cm})}{(-46.2\,\text{cm}) + (+22.4\,\text{cm})}\right) = \boxed{87.0\,\text{cm}}$$

31. The plane surface has an infinite radius of curvature. Let the plane surface be surface 2, so $R_2 = \infty$. The index of refraction is found in Table 32-1.

$$\frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) = \frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{\infty}\right) = \frac{(n-1)}{R_1} \rightarrow$$

$$R_1 = (n-1)\,f = (1.46-1)(18.7\,\text{cm}) = \boxed{8.6\,\text{cm}}$$

32. First we find the focal length from Eq. 33-3, the lensmaker's equation. Then we use Eq. 33-2 to find the image distance, and Eq. 33-3 to find the magnification.

$$\frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) \rightarrow$$

$$f = \frac{1}{(n-1)}\left(\frac{R_1 R_2}{R_1 + R_2}\right) = \frac{1}{(1.52-1)}\left(\frac{(-22.0\,\text{cm})(+18.5\,\text{cm})}{(-22.0\,\text{cm}) + (+18.5\,\text{cm})}\right) = 223.6\,\text{cm}$$

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} \rightarrow d_i = \frac{d_o f}{d_o - f} = \frac{(90.0\,\text{cm})(223.6\,\text{m})}{90.0\,\text{cm} - 223.6\,\text{cm}} = -150.6\,\text{cm} \approx \boxed{-151\,\text{cm}}$$

$$m = -\frac{d_i}{d_o} = -\frac{-150.6\,\text{cm}}{90.0\,\text{cm}} = \boxed{+1.67}$$

The image is virtual, in front of the lens, and upright.

33. Find the radius from the lensmaker's equation, Eq. 33-4.:

$$\frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) \rightarrow P = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) \rightarrow$$

$$R_2 = \frac{(n-1)R_1}{PR_1 - (n-1)} = \frac{(1.56-1)(0.300\,\text{m})}{(3.50\,\text{D})(0.300\,\text{m}) - (1.56-1)} = \boxed{0.34\,\text{m}}$$

34. The exposure is proportional to the product of the lens opening area and the exposure time, with the square of the *f*-stop number inversely proportional to the lens opening area. Setting the exposures equal for both exposure times we solve for the needed *f*-stop number.

$$t_1\left(f\text{-stop}_1\right)^{-2} = t_2\left(f\text{-stop}_2\right)^{-2} \rightarrow f\text{-stop}_2 = f\text{-stop}_1\sqrt{\frac{t_2}{t_1}} = 16\sqrt{\frac{1/1000\text{ s}}{1/120\text{ s}}} = 5.54 \text{ or } \boxed{\frac{f}{5.6}}$$

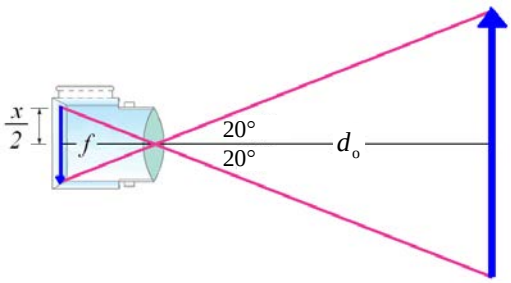
35. We find the *f*-number from $f\text{-stop} = f/D$.

$$f\text{-stop} = \frac{f}{D} = \frac{(17\text{ cm})}{(6.0\text{ cm})} = \boxed{\frac{f}{2.8}}$$

36. We use similar triangles, created from the distances between the centers of the two objects (H) and their ray traces to the hole (L_1) and the distance between the centers of the two images (h) and the distance of the screen to the hole (L_2) to determine the distance between the center of the two image circles. We then create similar triangles from the two ray traces for a single source with the base of one triangle equal to the diameter of the hole (d) , and the base of the second triangle equal to the diameter of the image circle (D). The heights for these two triangles are the distance from object to hole (L_1) and the distance from object to image ($L_1 + L_2$).

$$\frac{H}{L_1} = \frac{h}{L_2} \rightarrow h = H\frac{L_2}{L_1} = (2.0\text{ cm})\frac{7.0\text{ cm}}{100\text{ cm}} = 0.14\text{ cm} = 1.4\text{ mm}$$

$$\frac{d}{L_1} = \frac{D}{L_1 + L_2} \rightarrow D = d\frac{L_1 + L_2}{L_1} = (1.0\text{ mm})\frac{100\text{ cm} + 7.0\text{ cm}}{100\text{ cm}} = 1.07\text{ mm}$$



Since the separation distance of the two images is greater than their diameters, the two circles do not overlap.

37. We calculate the effective *f*-number for the pinhole camera by dividing the focal length by the diameter of the pinhole. The focal length is equal to the image distance. Setting the exposures equal for both cameras, where the exposure is proportional to the product of the exposure time and the area of the lens opening (which is inversely proportional to the square of the *f*-stop number), we solve for the exposure time.

$$f\text{-stop}_2 = \frac{f}{D} = \frac{(70\text{ mm})}{(1.0\text{ mm})} = \frac{f}{70}.$$

$$t_1\left(f\text{-stop}_1\right)^{-2} = t_2\left(f\text{-stop}_2\right)^{-2} \rightarrow t_2 = t_1\left(\frac{f\text{-stop}_2}{f\text{-stop}_1}\right)^2 = \frac{1}{250\text{ s}}\left(\frac{70}{11}\right)^2 = 0.16\text{ s} \approx \boxed{\tfrac{1}{6}\text{ s}}$$

38. Consider an object located a distance d_o from a converging lens of focal length f and its real image formed at distance d_i. If the distance d_o is much greater than the focal length, the lens equation tells us that the focal length and image distance are equal.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} \rightarrow d_i = \frac{fd_o}{d_o - f} \approx \frac{fd_o}{d_o} = f$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Thus, in a camera, the recording medium of spatial extent x is placed a distance equal to f behind the lens to form a focused image of a distant object. Assume the distant object subtends an angle of $40°$ at the position of the lens, so that the half-angle subtended is $20°$, as shown in the figure. We then use the tangent of this angle to determine the relationship between the focal length and half the image height.

$$\tan 20^\circ = \frac{\frac{1}{2}x}{f} \quad \rightarrow \quad f = \frac{x}{2\tan 20^\circ}$$

(*a*) For a 35-mm camera, we set $x = 36\text{ mm}$ to calculate the focal length.

$$f = \frac{36\text{ mm}}{2\tan 20^\circ} = \boxed{49\text{ mm}}$$

(*b*) For a digital camera, we set $x = 1.0\text{ cm} = 10\text{ mm}$.

$$f = \frac{10\text{ mm}}{2\tan 20^\circ} = \boxed{14\text{ mm}}$$

39. The image distance is found from Eq. 33-3, and then the focal length from Eq. 33-2. The image is inverted.

$$m = \frac{h_\text{i}}{h_\text{o}} = -\frac{d_\text{i}}{d_\text{o}} \quad \rightarrow \quad d_\text{i} = -d_\text{o}\frac{h_\text{i}}{h_\text{o}} = -(65\text{m})\frac{(-24\text{mm})}{(38\text{m})} = 41\text{mm}$$

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = \frac{d_\text{o}d_\text{i}}{d_\text{o}+d_\text{i}} = \frac{(65\text{m})(0.041\text{m})}{65\text{m} - 0.041\text{m}} = 0.041\text{m} = \boxed{41\text{mm}}$$

The object is essentially at infinity, so the image distance is equal to the focal length.

40. The length of the eyeball is the image distance for a far object, i.e., the focal length of the lens. We find the *f*-number from $f\text{-stop} = f/D$.

$$f\text{-stop} = \frac{f}{D} = \frac{(20\text{mm})}{(8.0\text{mm})} = \boxed{2.5 \text{ or } \frac{f}{2.5}}.$$

41. The actual near point of the person is 55 cm. With the lens, an object placed at the normal near point, 25 cm, or 23 cm from the lens, is to produce a virtual image 55 cm from the eye, or 53 cm from the lens. We find the power of the lens from Eqs. 33-1 and 33-3.

$$P = \frac{1}{f} = \frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{0.23\text{m}} + \frac{1}{-0.53\text{m}} = \boxed{2.5\text{D}}$$

42. The screen placed 55 cm from the eye, or 53.2 cm from the lens, is to produce a virtual image 105 cm from the eye, or 103.2 cm from the lens. Find the power of the lens from Eqs. 33-1 and 33-2.

$$P = \frac{1}{f} = \frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{0.532\text{m}} + \frac{1}{-1.032\text{m}} = \boxed{0.91\text{D}}$$

43. With the contact lens, an object at infinity should form a virtual image at the far point of the eye, 17 cm from the contact lens. Use that with Eq. 33-2 to find the focal length of the contact lens. We find the power of the lens from

$$\frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad \frac{1}{\infty} + \frac{1}{d_\text{i}} = \frac{1}{f} \quad \rightarrow \quad f = d_\text{i} = -17\text{cm}$$

Find the new near point as the object location that forms a virtual image at the actual near point of 12 cm from the contact lens. Again use Eq. 33-2.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad d_o=\frac{fd_i}{d_i-f}=\frac{(-17\,\text{cm})(-12\,\text{cm})}{(-12\,\text{cm})-(-17\,\text{cm})}=\boxed{41\,\text{cm}}$$

So the person would have to hold the object 41 cm from their eye to see it clearly. With glasses, they only had to hold the object 32 cm from the eye. So glasses would be better.

44. (*a*) Since the lens power is negative, the lens is diverging, so it produces images closer than the object. Thus the person is nearsighted.

(*b*) We find the far point by finding the image distance for an object at infinity. Since the lens is 2.0 cm in front of the eye, the far point is 2.0 cm farther than the absolute value of the image distance.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}=P \quad \rightarrow \quad \frac{1}{\infty}+\frac{1}{d_i}=-4.50\,\text{D} \rightarrow d_i=-\frac{1}{4.50\ \text{D}}=-0.222\ \text{m}=-22.2\ \text{cm}$$

$$\text{FP}=\left|-22.2\ \text{cm}\right|+2.0\ \text{cm}=\boxed{24.2\ \text{cm}}\ \text{from eye}$$

45. (*a*) The lens should put the image of an object at infinity at the person's far point of 78 cm. Note that the image is still in front of the eye, so the image distance is negative. Use Eqs. 33-2 and 33-1.

$$P=\frac{1}{f}=\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{\infty}+\frac{1}{(-0.78\,\text{m})}=-1.282\,\text{D}\approx\boxed{-1.3\,\text{D}}$$

(*b*) To find the near point with the lens in place, we find the object distance to form an image 25 cm in front of the eye.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}=P \quad \rightarrow \quad d_o=\frac{d_i}{Pd_i-1}=\frac{(-0.25\,\text{m})}{(-1.282\,\text{D})(-0.25\,\text{m})-1}=0.37\,\text{m}=\boxed{37\,\text{cm}}$$

46. The image of an object at infinity is to be formed 14 cm in front of the eye. So for glasses, the image distance is to be $d_i=-12\,\text{cm}$, and for contact lenses, the image distance is to be $d_i=-14\,\text{cm}$.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}=\frac{1}{\infty}+\frac{1}{d_i} \quad \rightarrow \quad f=d_i \quad \rightarrow \quad P=\frac{1}{f}=\frac{1}{d_i}$$

$$P_{\text{glasses}}=\frac{1}{-0.12\,\text{m}}=\boxed{-8.3\,\text{D}}\ ;\ P_{\text{contacts}}=\frac{1}{-0.14\,\text{m}}=\boxed{-7.1\,\text{D}}$$

47. Find the far point of the eye by finding the image distance FROM THE LENS for an object at infinity, using Eq. 33-2.

$$\frac{1}{d_{o1}}+\frac{1}{d_{i1}}=\frac{1}{f_1} \quad \rightarrow \quad \frac{1}{\infty}+\frac{1}{d_{i1}}=\frac{1}{f_1} \quad \rightarrow \quad d_{i1}=f_1=-23.0\,\text{cm}$$

Since the image is 23.0 in front of the lens, the image is 24.8 cm in front of the eye. The contact lens must put the image of an object at infinity at this same location. Use Eq. 33-2 for the contact lens with an image distance of -24.8 cm and an object distance of infinity.

$$\frac{1}{d_{o2}}+\frac{1}{d_{i2}}=\frac{1}{f_2} \quad \rightarrow \quad \frac{1}{\infty}+\frac{1}{d_{i2}}=\frac{1}{f_1} \quad \rightarrow \quad f_1=d_{i2}=\boxed{-24.8\,\text{cm}}$$

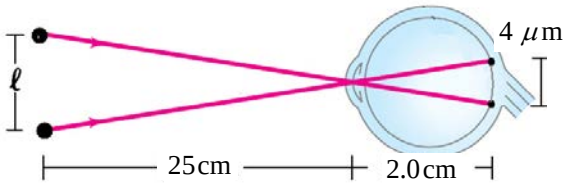
48. (*a*) We find the focal length of the lens for an object at infinity and the image on the retina. The image distance is thus 2.0 cm. Use Eq. 33-2.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad \frac{1}{\infty}+\frac{1}{2.0\,\text{cm}}=\frac{1}{f} \quad \rightarrow \quad f=\boxed{2.0\,\text{cm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We find the focal length of the lens for an object distance of 38 cm and an image distance of 2.0 cm. Again use Eq. 33.2.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad f=\frac{d_o d_i}{d_o+d_i}=\frac{(38\,\text{cm})(2.0\,\text{cm})}{(38\,\text{cm})+(2.0\,\text{cm})}=\boxed{1.9\,\text{cm}}$$



49. Find the object distance for the contact lens to form an image at the eye's near point, using Eqs. 33-2 and 33-1.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}=P \quad \rightarrow \quad d_o=\frac{d_i}{Pd_i-1}=\frac{-0.106\,\text{m}}{(-4.00\,\text{D})(-0.106\,\text{m})-1}=0.184\,\text{m}=\boxed{18.4\,\text{cm}}$$

Likewise find the object distance for the contact lens to form an image at the eye's far point.

$$d_o=\frac{d_i}{Pd_i-1}=\frac{-0.200\,\text{m}}{(-4.0\,\text{D})(-0.200\,\text{m})-1}=1.00\,\text{m}=\boxed{100\,\text{cm}} \text{ (3 sig. fig.)}$$

50. In the image we show the principal rays from each of the two points as they pass directly through the cornea and onto the lens. These two rays and the distance between the two objects, ℓ, and the distance between the two images (4 μm) create similar triangles. We set the ratio of the bases and heights of these two triangles equal to solve for ℓ.

$$\frac{\ell}{25\text{ cm}}=\frac{4\ \mu\text{m}}{2.0\text{ cm}} \rightarrow \ell=25\text{ cm}\frac{4\ \mu\text{m}}{2.0\text{ cm}}=\boxed{50\mu\text{m}}$$

51. We find the focal length from Eq. 33-6

$$M=\frac{N}{f} \quad \rightarrow \quad f=\frac{N}{M}=\frac{25\,\text{cm}}{3.8}=\boxed{6.6\,\text{cm}}$$

52. Find the magnification from Eq. 33-6.

$$M=\frac{N}{f}=\frac{(25\,\text{cm})}{(13\,\text{cm})}=\boxed{1.9\times}$$

53. (*a*) We find the focal length with the image at the near point from Eq. 33-6b.

$$M=1+\frac{N}{f} \quad \rightarrow \quad f=\frac{N}{M-1}=\frac{25\,\text{cm}}{3.0-1}=12.5\,\text{cm}\approx\boxed{13\,\text{cm}}$$

$$3.0=1+\frac{(25\,\text{cm})}{f_1}, \text{ which gives } f_1=12.5\,\text{cm}\approx\boxed{13\text{cm.}}$$

(*b*) If the eye is relaxed, the image is at infinity, and so use Eq. 33-6a.

$$M=\frac{N}{f} \quad \rightarrow \quad f=\frac{N}{M}=\frac{25\,\text{cm}}{3.0}=\boxed{8.3\,\text{cm}}$$

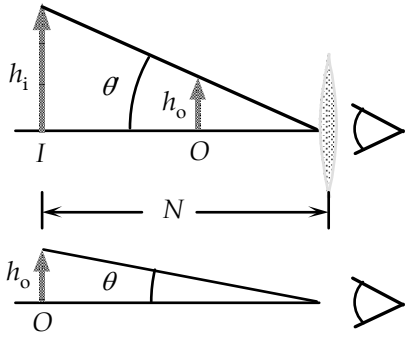
54. Maximum magnification is obtained with the image at the near point (which is negative). We find the object distance from Eq. 33-2, and the magnification from Eq. 33-6b.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \quad \rightarrow \quad d_o=\frac{d_i f}{d_i-f}=\frac{(-25.0\,\text{cm})(8.80\,\text{cm})}{(-25.0\,\text{cm})-(8.80\,\text{cm})}=\boxed{6.51\,\text{cm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$M = 1 + \frac{N}{f} = 1 + \frac{25.0\,\text{cm}}{8.80\,\text{cm}} = \boxed{3.84\times}$$

55. (*a*) We find the image distance from Eq. 33-2.



$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} \quad \rightarrow \quad d_i = \frac{fd_o}{d_o - f} = \frac{(6.00\,\text{cm})(5.85\,\text{cm})}{5.85\,\text{cm} - 6.00\,\text{cm}} = \boxed{-234\,\text{cm}}$$

(*b*) The angular magnification is given by Eq. 33-6a, since the eye will have to focus over 2 m away.

$$M = \frac{N}{f} = \frac{25.0\,\text{cm}}{6.00\,\text{cm}} = \boxed{4.17\times}$$

56. (*a*) We use Eq. 33-6b to calculate the angular magnification.

$$M = 1 + \frac{N}{f} = 1 + \frac{(25.0\,\text{cm})}{(9.60\,\text{cm})} = \boxed{3.60\times}$$

(*b*) Because the object without the lens and the image with the lens are at the near point, the angular magnification is also the ratio of widths. Using this relationship we calculate the image width.

$$M = \frac{h_i}{h_o} \rightarrow h_i = Mh_o = 3.60(3.40\,\text{mm}) = \boxed{12.3\,\text{mm}}$$

(*c*) We use Eq. 33-2 to calculate the object distance, with the image distance at -25.0 cm.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} \quad \rightarrow \quad d_o = \frac{fd_i}{d_i - f} = \frac{(9.60\,\text{cm})(-25.0\,\text{cm})}{-25.0\,\text{cm} - 9.60\,\text{cm}} = \boxed{6.94\,\text{cm}}$$

57. (*a*) We find the image distance using Eq. 33-2.

$$\frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f} \quad \rightarrow \quad d_i = \frac{fd_o}{d_o - f} = \frac{(9.5\,\text{cm})(8.3\,\text{cm})}{8.3\,\text{cm} - 9.5\,\text{cm}} = \boxed{-66\,\text{cm}}$$

(*b*) The angular magnification is found using Eq. 33-5, with the angles given as defined in Figure 33-33.

$$M = \frac{\theta'}{\theta} = \frac{(h_o/d_o)}{(h_o/N)} = \frac{N}{d_o} = \frac{25\text{ cm}}{8.3\text{ cm}} = \boxed{3.0\times}$$

58. First, find the focal length of the magnifying glass from Eq. 33-6a, for a relaxed eye (focused at infinity).

$$M = \frac{N}{f} \quad \rightarrow \quad f = \frac{N}{M} = \frac{25.0\,\text{cm}}{3.0} = 8.33\,\text{cm}$$

(*a*) Again use Eq. 33-6a for a different near point.

$$M_1 = \frac{N_1}{f} = \frac{(65\,\text{cm})}{(8.33\,\text{cm})} = \boxed{7.8\times}$$

(*b*) Again use Eq. 33-6a for a different near point.

$$M_2 = \frac{N_2}{f} = \frac{(17\,\text{cm})}{(8.33\,\text{cm})} = \boxed{2.0\times}$$

Without the lens, the closest an object can be placed is the near point. A farther near point means a smaller angle subtended by the object without the lens, and thus greater magnification.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

59. The focal length is 10 cm. First, find the object distance for an image at infinity. Then, find the object distance for an image 25 cm in front of the eye.

Initial: $\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \rightarrow \frac{1}{d_o}+\frac{1}{\infty}=\frac{1}{f} \rightarrow d_o = f = 12\,\text{cm}$

Final: $\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f} \rightarrow d_o = \frac{d_i f}{d_i - f} = \frac{(-25\,\text{cm})(12\,\text{cm})}{(-25\,\text{cm})-(12\,\text{cm})} = 8.1\,\text{cm}$

The lens was moved $12\,\text{cm} - 8.1\,\text{cm} = 3.9\,\text{cm} \approx$ 4 cm toward the fine print.

60. The magnification of the telescope is given by Eq. 33-7.

$$M = -\frac{f_o}{f_e} = -\frac{(78\,\text{cm})}{(2.8\,\text{cm})} = \boxed{-28\times}$$

For both object and image far away, the separation of the lenses is the sum of the focal lengths.

$$f_o + f_e = 78\,\text{cm} + 2.8\,\text{cm} = \boxed{81\,\text{cm}}$$

61. We find the focal length of the eyepiece from the magnification by Eq. 33-7.

$$M = -\frac{f_o}{f_e} \rightarrow f_e = -\frac{f_o}{M} = -\frac{88\,\text{cm}}{35\times} = \boxed{2.5\,\text{cm}}$$

For both object and image far away, the separation of the lenses is the sum of the focal lengths.

$$f_o + f_e = 88\,\text{cm} + 2.5\,\text{cm} = \boxed{91\,\text{cm}}$$

62. We find the focal length of the objective from Eq. 33-7.

$$M = f_o / f_e \rightarrow f_o = M f_e = (7.0)(3.0\,\text{cm}) = \boxed{21\,\text{cm}}$$

63. The magnification is given by Eq. 33-7.

$$M = -f_o / f_e == -f_o P_e = -(0.75\,\text{m})(35\,\text{D}) = \boxed{-26\times}$$

64. For a distant object and a relaxed eye (which means the image is at infinity), the separation of the eyepiece and objective lenses is the sum of their focal lengths. Use Eq. 33-7 to find the magnification.

$$\ell = f_o + f_e \;;\; M = -\frac{f_o}{f_e} = -\frac{f_o}{\ell - f_o} = -\frac{75.5\,\text{cm}}{78.0\,\text{cm} - 75.5\,\text{cm}} = \boxed{-30\times}$$

65. For a distant object and a relaxed eye (which means the image is at infinity), the separation of the eyepiece and objective lenses is the sum of their focal lengths. Use Eq. 33-7 to find the magnification.

$$\ell = f_o + f_e \;;\; M = -\frac{f_o}{f_e} = -\frac{f_o}{\ell - f_o} = -\frac{36.0\,\text{cm}}{33.8\,\text{cm} - 36.0\,\text{cm}} = \boxed{+16\times}$$

66. The focal length of the objective is just half the radius of curvature. Use Eq. 33-7 for the magnification.

$$M = -\frac{f_o}{f_e} = -\frac{\frac{1}{2}r}{f_e} = -\frac{3.2\,\text{m}}{0.028\,\text{m}} = -114\times \approx \boxed{-110\times}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

67. The focal length of the mirror is found from Eq. 33-7. The radius of curvature is twice the focal length.

$$M = -\frac{f_o}{f_e} \rightarrow f_o = -Mf_e = -(120)(0.031\text{m}) = 3.72\text{m} \approx \boxed{3.7\text{m}} \; ; \; r = 2f = \boxed{7.4\text{m}}$$

68. The relaxed eye means that the image is at infinity, and so the distance between the two lenses is 1.25 m. Use that relationship with Eq. 33-7 to solve for the focal lengths. Note that the magnification for an astronomical telescope is negative.

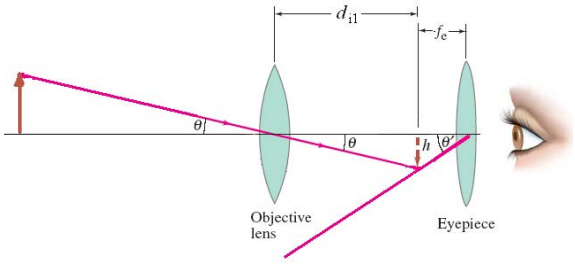
$$\ell = f_o + f_e \; ; \; M = -\frac{f_o}{f_e} = -\frac{f_o}{\ell - f_o} \rightarrow f_o = \frac{M\ell}{M-1} = \frac{-120(1.25\text{m})}{-120-1} = \boxed{1.24\text{m}}$$

$$f_e = \ell - f_o = 1.25\text{m} - 1.24\text{m} = 0.01\text{m} = \boxed{1\text{ cm}}$$

69. We use Eq. 33-6a and the magnification of the eyepiece to calculate the focal length of the eyepiece. We set the sum of the focal lengths equal to the length of the telescope to calculate the focal length of the objective. Then using both focal lengths in Eq. 33-7 we calculate the maximum magnification.

$$f_e = \frac{N}{M} = \frac{25\text{cm}}{5} = 5\text{cm} \; ; \; \ell = f_e + f_o \rightarrow f_o = \ell - f_e = 50\text{cm} - 5\text{cm} = 45\text{cm}$$

$$M = -\frac{f_o}{f_e} = -\frac{45\text{cm}}{5\text{cm}} = \boxed{-9\times}$$



70. Since the star is very far away, the image of the star from the objective mirror will be at the focal length of the objective, which is equal to one-half its radius of curvature (Eq. 32-1). We subtract this distance from the separation distance to determine the object distance for the second mirror. Then, using Eq. 33-2, we calculate the final image distance, which is where the sensor should be placed.

$$d_{i1} = f_o = \frac{R_o}{2} = \frac{3.00\text{m}}{2} = 1.50\text{m} \; ; \; d_{o2} = \ell - d_{i1} = 0.90\text{m} - 1.50\text{m} = -0.60\text{m}$$

$$\frac{1}{d_{o2}} + \frac{1}{d_{i2}} = \frac{1}{f_e} = \frac{2}{R_e} \rightarrow d_i = \frac{R_e d_{o2}}{2d_{o2} - R_e} = \frac{(-1.50\text{m})(-0.60\text{m})}{2(-0.60\text{m}) - (-1.50\text{m})} = \boxed{3.0\text{m}}$$

71. We assume a prism binocular so the magnification is positive, but simplify the diagram by ignoring the prisms. We find the focal length of the eyepiece using Eq. 33-7, with the design magnification.

$$f_e = \frac{f_o}{M} = \frac{26\text{cm}}{7.5} = 3.47\text{cm}$$

Using Eq. 33-2 and the objective focal length, we calculate the intermediate image distance. With the final image at infinity (relaxed eye), the secondary object distance is equal to the focal length of the eyepiece. We calculate the angular magnification using Eq. 33-5, with the angles shown in the diagram.

$$\frac{1}{d_{o1}} + \frac{1}{d_{i1}} = \frac{1}{f_o} \rightarrow d_{i1} = \frac{f_o d_{o`}}{d_{o1} - f_o} = \frac{(26\text{cm})(400\text{cm})}{400\text{cm} - 26\text{cm}} = 27.81\text{cm}$$

$$M = \frac{\theta'}{\theta} = \frac{h/f_e}{h/d_{i1}} = \frac{d_{i1}}{f_e} = \frac{27.81\text{cm}}{3.47\text{cm}} = \boxed{8.0\times}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

72. The magnification of the microscope is given by Eq. 33-10b.

$$M = \frac{N\ell}{f_o f_e} = \frac{(25\text{cm})(17.5\text{cm})}{(0.65\text{cm})(1.50\text{cm})} = 448.7\times \approx \boxed{450\times}$$

73. We find the focal length of the eyepiece from the magnification of the microscope, using the approximate results of Eq. 33-10b. We already know that $f_o \ll \ell$.

$$M \approx \frac{N\ell}{f_o f_e} \;\rightarrow\; f_e = \frac{N\ell}{Mf_o} = \frac{(25\text{cm})(17.5\text{cm})}{(680)(0.40\text{cm})} = \boxed{1.6\text{cm}}$$

Note that this also satisfies the assumption that $f_e \ll \ell$.

74. We use Eq. 33-10b.

$$M \approx \frac{N\ell}{f_e f_o} = \frac{(25\text{cm})(17\text{cm})}{(2.5\text{cm})(0.28\text{cm})} = 607.1\times \approx \boxed{610\times}$$

75. (*a*) The total magnification is found from Eq. 33-10a.

$$M = M_o M_e = (58.0)(13.0) = \boxed{754\times}$$

(*b*) With the final image at infinity, we find the focal length of the eyepiece using Eq. 33-9.

$$M_e = \frac{N}{f_e} \;\rightarrow\; f_e = \frac{N}{M_e} = \frac{25.0\text{cm}}{13.0} = 1.923\text{cm} \approx \boxed{1.92\text{cm}}$$

Since the image from the objective is at the focal point of the eyepiece, we set the image distance from the objective as the distance between the lenses less the focal length of the eyepiece. Using the image distance and magnification in Eq. 33-3, we calculate the initial object distance. Then using the image and object distance in Eq. 33-2 we calculate the objective focal length.

$$d_i = \ell - f_e = 20.0\text{cm} - 1.92\text{cm} = 18.08\text{cm}$$

$$m = \frac{d_i}{d_o} \rightarrow d_o = \frac{d_i}{m} = \frac{18.08\text{cm}}{58.0} = 0.312\text{cm}$$

$$\frac{1}{f_o} = \frac{1}{d_o} + \frac{1}{d_i} \rightarrow f_o = \frac{d_o d_i}{d_o + d_i} = \frac{(0.312\text{cm})(18.08\text{cm})}{0.312\text{cm} + 18.08\text{cm}} = \boxed{0.307\text{cm}}$$

(*c*) We found the object distance, in part (*b*), $d_o = \boxed{0.312\text{cm}}$.

76. (*a*) The total magnification is the product of the magnification of each lens, with the magnification of the eyepiece increased by one, as in Eq. 33-6b.

$$M = M_o(M_e + 1) = (58.0)(13.0 + 1.0) = \boxed{812\times}$$

(*b*) We find the focal length of the eyepiece using Eq. 33-6b.

$$(M_e + 1) = \frac{N}{f_e} + 1 \;\rightarrow\; f_e = \frac{N}{M_e} = \frac{25\text{cm}}{13.0} = \boxed{1.92\text{cm}}$$

Since the image from the eyepiece is at the near point, we use Eq. 33-2 to calculate the location of the object. This object distance is the location of the image from the objective. Subtracting this object distance from the distance between the lenses gives us the image distance from the objective. Using the image distance and magnification in Eq. 33-3, we calculate the initial object distance. Then using the image and object distance in Eq. 33-2 we calculate the objective focal length.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{1}{f_e}=\frac{1}{d_{o2}}+\frac{1}{d_{i2}} \quad \rightarrow \quad d_{o2}=\frac{f_e d_{i2}}{d_{i2}-f_e}=\frac{(1.92\,\text{cm})(-25.0\,\text{cm})}{-25.0\,\text{cm}-1.92\,\text{cm}}=1.78\,\text{cm}$$

$$d_{i1}=\ell - d_{o2}=20.0\,\text{cm}-1.78\,\text{cm}=18.22\,\text{cm}$$

$$m=\frac{d_i}{d_o} \quad \rightarrow \quad d_o=\frac{d_i}{m}=\frac{18.22\,\text{cm}}{58.0}=0.314\,\text{cm}$$

$$\frac{1}{f_o}=\frac{1}{d_o}+\frac{1}{d_i} \quad \rightarrow \quad f_o=\frac{d_o d_i}{d_o+d_i}=\frac{(0.314\,\text{cm})(18.22\,\text{cm})}{0.314\,\text{cm}+18.22\,\text{cm}}=\boxed{0.308\,\text{cm}}$$

(*c*) We found the object distance, in part (*b*), $d_o=\boxed{0.314\,\text{cm}}$.

77. (*a*) Since the final image is at infinity (relaxed eye) the image from the objective is at the focal point of the eyepiece. We subtract this distance from the distance between the lenses to calculate the objective image distance. Then using Eq. 33-2, we calculate the object distance.

$$d_{i1}=\ell - f_e=16.8\,\text{cm}-1.8\,\text{cm}=15.0\,\text{cm}$$

$$\frac{1}{f_o}=\frac{1}{d_{o1}}+\frac{1}{d_{i1}} \quad \rightarrow \quad d_{o1}=\frac{f_o d_{i1}}{d_{i1}-f_o}=\frac{(0.80\,\text{cm})(15.0\,\text{cm})}{15.0\,\text{cm}-0.80\,\text{cm}}=\boxed{0.85\,\text{cm}}$$

(*b*) With the final image at infinity, the magnification of the eyepiece is given by Eq. 33-10a.

$$M=\frac{N}{f_e}\left(\frac{\ell - f_e}{d_o}\right)=\frac{(25.0\,\text{cm})}{(1.8\,\text{cm})}\left(\frac{16.8\,\text{cm}-1.8\,\text{cm}}{0.85\,\text{cm}}\right)=247\times \approx \boxed{250\times}$$

78. (*a*) We find the image distance from the objective using Eq. 33-2. For the final image to be at infinity (viewed with a relaxed eye), the objective image distance must be at the focal distance of the eyepiece. We calculate the distance between the lenses as the sum of the objective image distance and the eyepiece focal length.

$$\frac{1}{d_{o1}}+\frac{1}{d_{i1}}=\frac{1}{f_o} \quad \rightarrow \quad d_{i1}=\frac{f_o d_{o1}}{d_{o1}-f_o}=\frac{(0.740\,\text{cm})(0.790\,\text{cm})}{0.790\,\text{cm}-0.740\,\text{cm}}=11.7\,\text{cm}$$

$$\ell = d_{i1}+f_e=11.7\,\text{cm}+2.80\,\text{cm}=\boxed{14.5\,\text{cm}}$$

(*b*) We use Eq. 33-10a to calculate the total magnification.

$$M=\frac{N}{f_e}\left(\frac{\ell - f_e}{d_o}\right)=\frac{(25.0\,\text{cm})}{(2.80\,\text{cm})}\left(\frac{14.5\,\text{cm}-2.80\,\text{cm}}{0.790\,\text{cm}}\right)=\boxed{132\times}$$

79. For each objective lens we set the image distance equal to the sum of the focal length and 160 mm. Then, using Eq. 33-2 we write a relation for the object distance in terms of the focal length. Using this relation in Eq. 33-3 we write an equation for the magnification in terms of the objective focal length. The total magnification is the product of the magnification of the objective and focal length.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f_o} \quad \rightarrow \quad \frac{1}{d_o}=\frac{1}{f_o}-\frac{1}{d_i} \quad \rightarrow \quad \frac{1}{d_o}=\frac{1}{f_o}-\frac{1}{f_o+160\text{ mm}} \quad \rightarrow \quad d_o=\frac{f_o(f_o+160\text{ mm})}{160\text{ mm}}$$

$$m_o=\frac{d_i}{d_o}=\frac{f_o+160\,\text{mm}}{\left[\dfrac{f_o(f_o+160\,\text{mm})}{160\text{ mm}}\right]}=\frac{160\text{ mm}}{f_o}$$

Since the objective magnification is inversely proportional to the focal length, the objective with the smallest focal length $(f_o=3.9\text{ mm})$ combined with the largest eyepiece magnification $(M_e=10)$ yields the largest overall magnification. The objective with the largest focal length $(f_o=32\text{ mm})$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

coupled with the smallest eyepiece magnification $(M_e = 5)$ yields the smallest overall magnification.

$$M_{\text{largest}} = \frac{160\,\text{mm}}{3.9\,\text{mm}}(10\times) = \boxed{410\times} \;;\; M_{\text{smallest}} = \frac{160\,\text{mm}}{32\,\text{mm}}(5\times) = \boxed{25\times}$$

80. (*a*) For this microscope both the objective and eyepiece have focal lengths of 12 cm. Since the final image is at infinity (relaxed eye) the image from the objective must be at the focal length of the eyepiece. The objective image distance must therefore be equal to the distance between the lenses less the focal length of the objective. We calculate the object distance by inserting the objective focal length and image distance into Eq. 33-2.

$$d_{i1} = \ell - f_e = 55\,\text{cm} - 12\,\text{cm} = 43\,\text{cm}$$

$$\frac{1}{f_o} = \frac{1}{d_o} + \frac{1}{d_{i1}} \;\rightarrow\; d_o = \frac{f_o d_{i1}}{d_{i1} - f_o} = \frac{(12\,\text{cm})(43\,\text{cm})}{43\,\text{cm} - 12\,\text{cm}} = 16.65\,\text{cm} \approx \boxed{17\,\text{cm}}$$

(*b*) We calculate the magnification using Eq. 33-10a.

$$M = \frac{N}{f_e}\left(\frac{\ell - f_e}{d_o}\right) = \frac{(25\,\text{cm})}{(12\,\text{cm})}\left(\frac{55\,\text{cm} - 12\,\text{cm}}{16.65\,\text{cm}}\right) = 5.38\times \approx \boxed{5.4\times}$$

(*c*) We calculate the magnification using Eq. 33-10b, and divide the result by the answer to part (*b*) to determine the percent difference.

$$M_{\text{approx}} \approx \frac{N\ell}{f_e f_o} = \frac{(25\,\text{cm})(55\,\text{cm})}{(12\,\text{cm})(\ 12\,\text{cm})} = 9.55\times \;;\; \frac{M_{\text{approx}} - M}{M} = \frac{9.55 - 5.38}{5.38} = 0.775 \approx \boxed{78\%}$$

81. We use Eq. 33-4 to find the focal length for each color, and then Eq. 33-2 to find the image distance. For the plano-convex lens, $R_1 > 0$ and $R_2 = \infty$.

$$\frac{1}{f_{\text{red}}} = (n_{\text{red}} - 1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) = (1.5106 - 1)\left[\left(\frac{1}{18.4\,\text{cm}}\right) + \left(\frac{1}{\infty}\right)\right] \;\rightarrow\; f_{\text{red}} = 36.036\,\text{cm}$$

$$\frac{1}{f_{\text{yellow}}} = (n_{\text{yellow}} - 1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right) = (1.5226 - 1)\left[\left(\frac{1}{18.4\,\text{cm}}\right) + \left(\frac{1}{\infty}\right)\right] \;\rightarrow\; f_{\text{orange}} = 35.209\,\text{cm}$$

We find the image distances from

$$\frac{1}{d_o} + \frac{1}{d_{i\,\text{red}}} = \frac{1}{f_{\text{red}}} \;\rightarrow\; d_{i\,\text{red}} = \frac{d_o f_{\text{red}}}{d_o - f_{\text{red}}} = \frac{(66.0\,\text{cm})(36.036\,\text{cm})}{(66.0\,\text{cm}) - (36.036\,\text{cm})} = 79.374\,\text{cm} \approx \boxed{79.4\,\text{cm}}$$

$$\frac{1}{d_o} + \frac{1}{d_{i\,\text{yellow}}} = \frac{1}{f_{\text{yellow}}} \;\rightarrow\; d_{i\,\text{yellow}} = \frac{d_o f_{\text{yellow}}}{d_o - f_{\text{yellow}}} = \frac{(66.0\,\text{cm})(35.209\,\text{cm})}{(66.0\,\text{cm}) - (35.209\,\text{cm})} = 75.469\,\text{cm} \approx \boxed{75.5\,\text{cm}}$$

The images are 3.9 cm apart, an example of chromatic aberration.

82. From Problem 26 we have a relationship between the individual focal lengths and the focal length of the combination.

$$\frac{1}{f_D} = -\frac{1}{f_C} + \frac{1}{f_T} \;\rightarrow\; \frac{1}{f_T} = \frac{1}{f_D} + \frac{1}{f_C} \;\rightarrow\; f_T = \frac{f_C f_D}{f_C + f_D} = \frac{(25\,\text{cm})(-28\,\text{cm})}{(25\,\text{cm}) + (-28\,\text{cm})} = 233\,\text{cm}$$

(*a*) The combination is converging, since the focal length is positive. Also, the converging lens is "stronger" than the diverging lens since it has a smaller absolute focal length (or higher absolute power).

(*b*) From above, $f_T \approx \boxed{230\,\text{cm}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

83. We calculate the range object distances from Eq. 33-2 using the given focal length and maximum and minimum image distances.

$$\frac{1}{f}=\frac{1}{d_{\text{o}}}+\frac{1}{d_{\text{i}}} \quad \rightarrow \quad d_{\text{o,min}}=\frac{fd_{\text{i,max}}}{d_{\text{i,max}}-f}=\frac{(200.0\,\text{mm})(206.4\,\text{mm})}{206.4\,\text{mm}-200.0\,\text{mm}}=6450\,\text{mm}=6.45\,\text{m}$$

$$d_{\text{o,max}}=\frac{fd_{\text{i,min}}}{d_{\text{i,min}}-f}=\frac{(200.0\,\text{mm})(200.0\,\text{mm})}{200.0\,\text{mm}-200.0\,\text{mm}}=\infty$$

Thus the range of object distances is $\boxed{6.45\,\text{m}\le d_{\text{o}}<\infty}$.

84. We calculate the maximum and minimum image distances from Eq. 33-2, using the given focal length and maximum and minimum object distances. Subtracting these two distances gives the distance over which the lens must move relative to the plane of the sensor or film.

$$\frac{1}{f}=\frac{1}{d_{\text{o}}}+\frac{1}{d_{\text{i}}} \quad \rightarrow \quad d_{\text{i,max}}=\frac{fd_{\text{o,min}}}{d_{\text{o,min}}-f}=\frac{(135\,\text{mm})(1.30\,\text{m})}{1300\,\text{mm}-135\,\text{mm}}=0.151\,\text{m}=151\,\text{mm}$$

$$d_{\text{i,min}}=\frac{fd_{\text{o,max}}}{d_{\text{o,max}}-f}=\frac{(135\,\text{mm})(\infty)}{\infty-135\,\text{mm}}=135\,\text{mm}$$

$$\Delta d=d_{\text{i,max}}-d_{\text{i,min}}=151\,\text{mm}-135\,\text{mm}=\boxed{16\,\text{mm}}$$

85. Since the object height is equal to the image height, the magnification is –1. We use Eq. 33-3 to obtain the image distance in terms of the object distance. Then we use this relationship with Eq. 33-2 to solve for the object distance.

$$m=-1=-\frac{d_{\text{i}}}{d_{\text{o}}} \quad \rightarrow \quad d_{\text{i}}=d_{\text{o}}$$

$$\frac{1}{f}=\frac{1}{d_{\text{o}}}+\frac{1}{d_{\text{i}}}=\frac{1}{d_{\text{o}}}+\frac{1}{d_{\text{o}}}=\frac{2}{d_{\text{o}}} \quad \rightarrow \quad d_{o}=2f=2(58\,\text{mm})=\boxed{116\,\text{mm}}$$

The distance between the object and the film is the sum of the object and image distances.

$$d=d_{\text{o}}+d_{\text{i}}=d_{\text{o}}+d_{\text{o}}=2d_{\text{o}}=2(116\text{ mm})=\boxed{232\,\text{mm}}$$

86. When an object is very far away, the image will be at the focal point. We set the image distance in Eq. 33-3 equal to the focal length to show that the magnification is proportional to the focal length.

$$m=-\frac{d_{\text{i}}}{d_{\text{o}}}=-\frac{f}{d_{\text{o}}}=\left(-\frac{1}{d_{\text{o}}}\right)f=(\text{constant})\,f \quad \rightarrow \quad \boxed{m\propto f}$$

87. We use Eq. 33-2 with the final image distance and focal length of the converging lens to determine the location of the object for the second lens. Subtracting this distance from the separation distance between the lenses gives us the image distance from the first lens. Inserting this image distance and object distance into Eq. 33-2, we calculate the focal length of the diverging lens.

$$\frac{1}{d_{\text{o2}}}+\frac{1}{d_{\text{i2}}}=\frac{1}{f_2} \quad \rightarrow \quad d_{\text{o2}}=\frac{d_{\text{i2}}f_2}{d_{\text{i2}}-f_2}=\frac{(17.0\,\text{cm})(12.0\,\text{cm})}{17.0\,\text{cm}-12.0\,\text{cm}}=40.8\,\text{cm}$$

$$d_{\text{i1}}=\ell-d_{\text{o2}}=30.0\,\text{cm}-40.8\,\text{cm}=-10.8\,\text{cm}$$

$$\frac{1}{d_{\text{o1}}}+\frac{1}{d_{\text{i1}}}=\frac{1}{f_1} \quad \rightarrow \quad f_1=\frac{d_{i1}d_{\text{o1}}}{d_{\text{i1}}+d_{\text{o1}}}=\frac{(-10.8\,\text{cm})(25.0\,\text{cm})}{-10.8\,\text{cm}+25.0\,\text{cm}}=\boxed{-19.0\,\text{cm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

88. The relationship between two lenses in contact was found in Problem 26. We use this resulting equation to solve for the combination focal length.

$$\frac{1}{f_T}=\frac{1}{f_D}+\frac{1}{f_C} \quad \rightarrow \quad f_T=\frac{f_D f_C}{f_D+f_C}=\frac{(-20.0\,\text{cm})(13.0\,\text{cm})}{-20.0\,\text{cm}+13.0\,\text{cm}}=\boxed{37.1\,\text{cm}}$$

Since the focal length is positive, the combination is a converging lens.

89. We use Eq. 33-7, which relates the magnification to the focal lengths, to write the focal length of the objective lens in terms of the magnification and focal length of the eyepiece. Then setting the sum of the focal lengths equal to the length of the telescope we solve for the focal length of the eyepiece and the focal length of the objective.

$$M=-\frac{f_o}{f_e} \quad \rightarrow \quad f_o=-Mf_e \;;\; \ell=f_e+f_o=f_e(1-M) \quad \rightarrow \quad f_e=\frac{\ell}{1-M}=\frac{28\,\text{cm}}{1-(-8.0)}=\boxed{3.1\,\text{cm}}$$

$$f_o=\ell-f_e=28\,\text{cm}-3.1\,\text{cm}=\boxed{25\,\text{cm}}$$

90. (*a*) When two lenses are placed in contact, the negative of the image of the first lens is the object distance of the second. Using Eq. 33-2, we solve for the image distance of the first lens. Inserting the negative of this image distance into the lens equation for the second lens we obtain a relationship between the initial object distance and final image distance. Again using the lens equation with this relationship, we obtain the focal length of the lens combination.

$$\frac{1}{f_1}=\frac{1}{d_{o1}}+\frac{1}{d_{i1}} \quad \rightarrow \quad \frac{1}{d_{i1}}=\frac{1}{f_1}-\frac{1}{d_{o1}}=-\frac{1}{d_{o2}}$$

$$\frac{1}{f_2}=\frac{1}{d_{o2}}+\frac{1}{d_{i2}}=\frac{1}{d_{o2}}-\left(\frac{1}{f_1}-\frac{1}{d_{o1}}\right)\Rightarrow\frac{1}{f_2}+\frac{1}{f_1}=\frac{1}{d_{o2}}+\frac{1}{d_{o1}}=\frac{1}{f_T}$$

$$\frac{1}{f_T}=\frac{1}{f_1}+\frac{1}{f_2} \quad \rightarrow \quad \boxed{f_T=\frac{f_1 f_2}{f_1+f_2}}$$

(*b*) Setting the power equal to the inverse of the focal length gives the relationship between powers of adjacent lenses.

$$\frac{1}{f_T}=\frac{1}{f_1}+\frac{1}{f_2}\Rightarrow\boxed{P_T=P_1+P_2}$$

91. (*a*) Because the Sun is very far away, the image will be at the focal point, or $d_i=f$. We find the magnitude of the size of the image using Eq. 33-3, with the image distance equal to 28 mm.

$$\frac{h_i}{h_o}=\frac{-d_i}{d_o} \quad \rightarrow \quad |h_i|=\frac{h_o d_i}{d_o}=\frac{(1.4\times10^6\,\text{km})(28\,\text{mm})}{1.5\times10^8\,\text{km}}=\boxed{0.26\,\text{mm}}$$

(*b*) We repeat the same calculation with a 50 mm image distance.

$$|h_i|=\frac{(1.4\times10^6\,\text{km})(50\,\text{mm})}{1.5\times10^8\,\text{km}}=\boxed{0.47\,\text{mm}}$$

(*c*) Again, with a 135 mm image distance.

$$|h_i|=\frac{(1.4\times10^6\,\text{km})(135\,\text{mm})}{1.5\times10^8\,\text{km}}=\boxed{1.3\,\text{mm}}$$

(*d*) The equations show that image height is directly proportional to focal length. Therefore the relative magnifications will be the ratio of focal lengths.

$\frac{28\,\text{mm}}{50\,\text{mm}}=\boxed{0.56\times}$ for the 28 mm lens ; $\frac{135\,\text{mm}}{50\,\text{mm}}=\boxed{2.7\times}$ for the 135 mm lens.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

92. We solve this problem by working through the lenses "backwards." We use the image distances and focal lengths to calculate the object distances. Since the final image from the right lens is halfway between the lenses, we set the image distance of the second lens equal to the negative of half the distance between the lenses. Using Eq. 33-2, we solve for the object distance of this lens. By subtracting this object distance from the distance between the two lenses, we find the image distance from the first lens. Then using Eq. 33-2 again, we solve for the initial object distance.

$$d_{i2} = -\tfrac{1}{2}\ell = -\tfrac{1}{2}(30.0\,\text{cm}) = -15.0\,\text{cm}$$

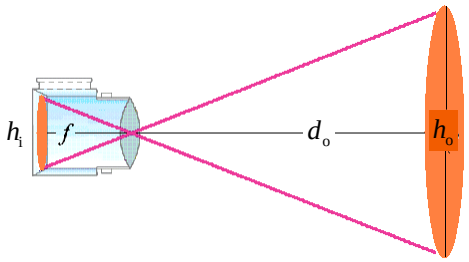
$$\frac{1}{d_{o2}} + \frac{1}{d_{i2}} = \frac{1}{f_2} \quad \rightarrow \quad d_{o2} = \frac{d_{i2} f_2}{d_{i2} - f_2} = \frac{(-15.0\,\text{cm})(20.0\,\text{cm})}{-15.0\,\text{cm} - 20.0\,\text{cm}} = 8.57\,\text{cm}$$

$$d_{i1} = \ell - d_{o2} = 30.0\ \text{cm} - 8.57\ \text{cm} = 21.4\ \text{cm}$$

$$\frac{1}{d_{o1}} + \frac{1}{d_{i1}} = \frac{1}{f_1} \quad \rightarrow \quad d_{o1} = \frac{d_{i1} f_1}{d_{i1} - f_1} = \frac{(21.4\,\text{cm})(15.0\,\text{cm})}{21.4\,\text{cm} - 15.0\,\text{cm}} = \boxed{50.0\,\text{cm}}$$

93. We set d_i as the original image distance and $d_i + 10.0\,\text{cm}$ as the new image distance. Then using Eq. 33-2 for both cases, we eliminate the focal length and solve for the image distance. We insert the real image distance into the initial lens equation and solve for the focal length.

$$\frac{1}{d_{o1}} + \frac{1}{d_i} = \frac{1}{f} = \frac{1}{d_{o2}} + \frac{1}{d_i + 10.0\,\text{cm}} \quad \rightarrow \quad \frac{1}{d_{o1}} - \frac{1}{d_{o2}} = \frac{1}{d_i + 10.0\,\text{cm}} - \frac{1}{d_i} = \frac{-10.0\,\text{cm}}{d_i (d_i + 10.0\,\text{cm})}$$



$$\frac{1}{60.0\,\text{cm}} - \frac{1}{40.0\,\text{cm}} = \frac{-10.0\,\text{cm}}{d_i (d_i + 10.0\,\text{cm})} \quad \rightarrow \quad d_i^2 + (10.0\,\text{cm}) d_i - 1200\,\text{cm}^2 = 0$$

$$d_i = -40.0\,\text{cm} \ \text{ or } 30.0\,\text{cm}$$

Only the positive image distance will produce the real image.

$$\frac{1}{f} = \frac{1}{d_{o1}} + \frac{1}{d_i} \Rightarrow f = \frac{d_i d_{o1}}{d_i + d_{o1}} = \frac{(30.0\,\text{cm})(60.0\,\text{cm})}{30.0\,\text{cm} + 60.0\,\text{cm}} = \boxed{20.0\,\text{cm}}$$

94. Since the distance to the sun is much larger than the telescope's focal length, the image distance is about equal to the focal length. Rays from the top and bottom edges of the sun pass through the lens unrefracted. These rays with the object and image heights form similar triangles. We calculate the focal length of the telescope by setting the ratio of height to base for each triangle equal.

$$\frac{f}{h_i} = \frac{d_o}{h_o} \quad \rightarrow$$

$$f = h_i \frac{d_o}{h_o} = (15\ \text{mm}) \frac{1.5 \times 10^8\ \text{km}}{1.4 \times 10^6\ \text{km}} = 1607\ \text{mm} \approx \boxed{1.6\ \text{m}}$$

95. We use Eq. 33-3 to write the image distance in terms of the object distance, image height, and object height. Then using Eq. 33-2 we solve for the object distance, which is the distance between the photographer and the subject.

$$m = \frac{h_i}{h_o} = -\frac{d_i}{d_o} \quad \rightarrow \quad \frac{1}{d_i} = -\frac{h_o}{h_i}\frac{1}{d_o}$$

$$\frac{1}{f} = \frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{d_o} + \left(-\frac{h_o}{h_i}\frac{1}{d_o}\right) = \left(1 - \frac{h_o}{h_i}\right)\frac{1}{d_o} \quad \rightarrow$$

$$d_o = \left(1 - \frac{h_o}{h_i}\right) f = \left(1 - \frac{1750\,\text{mm}}{-8.25\,\text{mm}}\right)(220\,\text{mm}) = 46{,}900\,\text{mm} \approx \boxed{47\,\text{m}}$$

96. The exposure is proportional to the intensity of light, the area of the shutter, and the time. The area of the shutter is proportional to the square of the diameter or inversely proportional to the square of the *f*-stop. Setting the two proportionalities equal, with constant time, we solve for the change in intensity.

$$\frac{I_1 t}{(f\text{-stop}_1)^2} = \frac{I_2 t}{(f\text{-stop}_2)^2} \quad \rightarrow \quad \frac{I_2}{I_1} = \left(\frac{f\text{-stop}_2}{f\text{-stop}_1}\right)^2 = \left(\frac{16}{5.6}\right)^2 = \boxed{8.2}$$

97. The maximum magnification is achieved with the image at the near point, using Eq. 33-6b.

$$M_1 = 1 + \frac{N_1}{f} = 1 + \frac{(15.0\,\text{cm})}{(8.5\,\text{cm})} = \boxed{2.8\times}$$

For an adult we set the near point equal to 25.0 cm.

$$M_2 = 1 + \frac{N_2}{f} = 1 + \frac{(25.0\,\text{cm})}{(8.5\,\text{cm})} = \boxed{3.9\times}$$

The person with the normal eye (adult) sees more detail.

98. The actual far point of the person is 155cm. With the lens, an object far away is to produce a virtual image 155cm from the eye, or 153cm from the lens. We calculate the power of the upper part of the bifocals using Eq. 33-2 with the power equal to the inverse of the focal length in meter.

$$P_1 = \frac{1}{f_1} = \left(\frac{1}{d_{o1}}\right) + \left(\frac{1}{d_{i1}}\right) = \left(\frac{1}{\infty}\right) + \left(\frac{1}{-1.53\,\text{m}}\right) = \boxed{-0.65\ \text{D (upper part)}}$$

The actual near point of the person is 45cm. With the lens, an object placed at the normal near point, 25 cm, or 23 cm from the lens, is to produce a virtual image 45cm from the eye, or 43cm from the lens. We again calculate the power using Eq. 33-2.

$$P_2 = \frac{1}{f_2} = \left(\frac{1}{d_{o2}}\right) + \left(\frac{1}{d_{i2}}\right) = \left(\frac{1}{0.23\,\text{m}}\right) + \left(\frac{1}{-0.43\,\text{m}}\right) = \boxed{+2.0\ \text{D (lower part)}}$$

99. The magnification for a relaxed eye is given by Eq. 33-6a.

$$M = N/f = NP = (0.25\,\text{m})(+4.0\,\text{D}) = \boxed{1.0\times.}$$

100. (*a*) The magnification of the telescope is given by Eq. 33-7. The focal lengths are expressed in terms of their powers.

$$M = -\frac{f_o}{f_e} = -\frac{P_e}{P_o} = -\frac{(4.5\,\text{D})}{(2.0\,\text{D})} = -2.25\times \approx \boxed{-2.3\times}$$

(*b*) To get a magnification greater than 1, for the eyepiece we use the lens with the smaller focal length, or greater power: 4.5 D.

101. We calculate the man's near point (d_i) using Eq. 33-2, with the initial object at 0.32 m with a 2.5 D lens. To give him a normal near point, we set the final object distance as 0.25 m and calculate the power necessary to have the image at his actual near point.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$P_1 = \frac{1}{d_i} + \frac{1}{d_{o1}} \;\rightarrow\; \frac{1}{d_i} = P_1 - \frac{1}{d_{o1}} \;\rightarrow\; d_i = \frac{d_{o1}}{P_1 d_{o1} - 1} = \frac{0.32\,\text{m}}{(2.5\,\text{D})(0.32\,\text{m}) - 1} = -1.6\,\text{m}$$

$$P_2 = \frac{1}{d_i} + \frac{1}{d_{o2}} = \left(P_1 - \frac{1}{d_{o1}}\right) + \frac{1}{d_{o2}} = \left(+2.5\text{ D} - \frac{1}{0.32\text{ m}}\right) + \frac{1}{0.25\text{ m}} = \boxed{+3.4\text{ D}}$$

102. (*a*) We solve Eq. 33-2 for the image distance. Then taking the time derivative of the image distance gives the image velocity. If the velocity of the object is taken to be positive, then the image distance is decreasing, and so $v_o = -\frac{d}{dt}(d_o)$.

$$\frac{1}{f} = \frac{1}{d_i} + \frac{1}{d_o} \;\rightarrow\; d_i = \frac{f d_o}{d_o - f}$$

$$v_i = \frac{d}{dt}(d_i) = \frac{d}{dt}\left(\frac{f d_o}{d_o - f}\right) = \frac{f}{d_o - f}(-v_o) - \frac{f d_o}{(d_o - f)^2}(-v_o) = \frac{f(d_o - f) - f d_o}{(d_o - f)^2}(-v_o)$$

$$= \boxed{\frac{f^2 v_o}{(d_o - f)^2}}$$

(*b*) The velocity of the image is positive, which means the image is moving the same direction as the object. But since the image is on the opposite side of the lens as the object, the image must be moving away from the lens.

(*c*) We set the image and object velocities equal and solve for the image distance.

$$v_i = v_o \;\rightarrow\; \frac{f^2 v_o}{(d_o - f)^2} = v_o \;\rightarrow\; (d_o - f)^2 = f^2 \;\rightarrow\; d_o - f = f \;\rightarrow\; \boxed{d_o = 2f}$$

103. The focal length of the eyepiece is found using Eq. 33-1.

$$f_e = \frac{1}{P_e} = \frac{1}{23\text{ D}} = 4.3 \times 10^{-2}\,\text{m} = 4.3\,\text{cm}.$$

For both object and image far away, we find the focal length of the objective from the separation of the lenses.

$$\ell = f_o + f_e \;\rightarrow\; f_o = \ell - f_e = 85\,\text{cm} - 4.3\,\text{cm} = 80.7\,\text{cm}$$

The magnification of the telescope is given by Eq. 33-7.

$$M = -\frac{f_o}{f_e} = -\frac{(80.7\,\text{cm})}{(4.3\,\text{cm})} = \boxed{-19\times}$$

104. (*a*) The length of the telescope is the sum of the focal lengths. The magnification is the ratio of the focal lengths (Eq. 33-7). For a magnification greater than one, the lens with the smaller focal length should be the eyepiece. Therefore the 4.0 cm lens should be the eyepiece.

$$\ell = f_o + f_e = 4.0\,\text{cm} + 44\,\text{cm} = \boxed{48\,\text{cm}}$$

$$M = -\frac{f_o}{f_e} = -\frac{(44\,\text{cm})}{(4.0\,\text{cm})} = \boxed{-11\times}$$

(*b*) We use Eq. 33-10b to solve for the length, ℓ, of the microscope.

$$M = -\frac{N\ell}{f_e f_o} \;\Rightarrow\; \ell = \frac{-M f_e f_o}{N} = \frac{-(25)(4.0\text{ cm})(44\text{ cm})}{25\text{ cm}} = 180\text{ cm} = \boxed{1.8\text{ m}}$$

This is far too long to be practical.

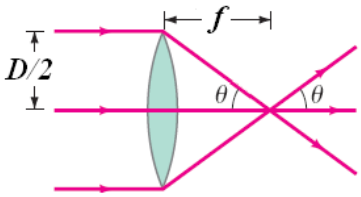
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

105. (*a*) The focal length of the lens is the inverse of the power.

$$f = \frac{1}{P} = \frac{1}{3.50\,\text{D}} = 0.286\,\text{m} = \boxed{28.6\,\text{cm.}}$$

(*b*) The lens produces a virtual image at his near point. We set the object distance at 23 cm from the glass (25 cm from the eyes) and solve for the image distance. We add the two centimeters between the glass and eyes to determine the near point.

$$P = \frac{1}{f} = \frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} \quad \rightarrow \quad d_\text{i} = \left(P - \frac{1}{d_\text{o}} \right)^{-1} = \left(3.50\,\text{D} - \frac{1}{0.23\,\text{m}} \right)^{-1} = -1.18\,\text{m}$$



$$N = |d_i| + 0.02\,\text{m} = 1.18\,\text{m} + 0.02\,\text{m} = \boxed{1.20\,\text{m}}$$

(*c*) For Pam, find the object distance that has an image at her near point, –0.23 m from the lens.

$$P = \frac{1}{f} = \frac{1}{d_\text{o}} + \frac{1}{d_\text{i}} \quad \rightarrow \quad d_\text{o} = \left(P - \frac{1}{d_\text{i}} \right)^{-1} = \left(3.50\ \text{D} - \frac{1}{-0.23\ \text{m}} \right)^{-1} = 0.13\,\text{m}$$

Pam's near point with the glasses is 13 cm from the glasses or $\boxed{15\ \text{cm}}$ from her eyes.

106. As shown in the image, the parallel rays will pass through a single point located at the focal distance from the lens. The ray passing through the edge of the lens (a distance D/2 from the principal axis) makes an angle θ with the principal axis. We set the tangent of this angle equal to the ratio of the opposite side ($D/2$) to the adjacent side (f) and solve for the focal length.

$$\tan\theta = \frac{D/2}{f} \rightarrow f = \frac{D}{2\tan\theta} = \frac{5.0\ \text{cm}}{2\tan 3.5°} = \boxed{41\ \text{cm}}$$

107. We use Eq. 33-6b to calculate the necessary focal length for a magnifying glass held at the near point ($N = 25\,\text{cm}$) to have a magnification of $M = 3.0$.

$$M = \frac{N}{f} + 1 \quad \rightarrow \quad f = \frac{N}{M-1} = \frac{25\,\text{cm}}{3.0-1} = 12.5\,\text{cm}$$

In the text, the lensmaker's equation (Eq. 33-4) is derived assuming the lens is composed of material with index of refraction n and is surrounded by air, whose index of refraction is $n_a = 1$. We now modify this derivation, with the lens composed of air with index of refraction $n_a = 1$ surrounded by water, whose index of refraction is $n_\text{w} = 1.33$. In the proof of the lensmaker's equation, Snell's law at small angles is first applied at both surfaces of the lens.

$$n_\text{w} \sin\theta_1 = n \sin\theta_2 \quad \rightarrow \quad n_\text{w}\theta_1 \approx \theta_2 \quad \rightarrow \quad \theta_1 \approx \frac{1}{n_\text{w}}\theta_2$$

$$n \sin\theta_3 = n_\text{w} \sin\theta_4 \quad \rightarrow \quad \theta_3 \approx n_\text{w}\theta_4 \quad \rightarrow \quad \frac{1}{n_\text{w}}\theta_3 \approx \theta_4$$

These equations are the same as those following Fig. 33-16, but with *n* replaced by $1/n_\text{w}$. The rest of the derivation is the same, so we can rewrite the lensmaker's equation with this single modification. We assume the radii are equal, insert the necessary focal length, and solve for the radius of curvature

$$\frac{1}{f} = \left(\frac{1}{n_\text{w}} - 1 \right) \left[\frac{1}{R_1} + \frac{1}{R_2} \right] = \left(\frac{1}{n_\text{w}} - 1 \right) \left[\frac{1}{R} + \frac{1}{R} \right] = \left(\frac{1}{n_\text{w}} - 1 \right) \left[\frac{2}{R} \right]$$

$$R = 2f \left(\frac{1}{n_\text{w}} - 1 \right) = 2(12.5\ \text{cm}) \left(\frac{1}{1.33} - 1 \right) = -6.20\,\text{cm} \approx \boxed{-6.2\,\text{cm}}$$

The lens is therefore a $\boxed{\text{concave lens}}$ with radii of curvature –6.2 cm.

108. (*a*) We use Eq. 32-2 to calculate the image distance and then use the object and image distances in Eq. 32-3 to calculate the magnification. We finally make the approximation that the object distance is much larger than the focal length.

$$\frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f_1} \quad \rightarrow \quad d_i=\left(\frac{1}{f_1}-\frac{1}{d_o}\right)^{-1}=\frac{f_1 d_o}{d_o-f_1}$$

$$m_1=-\frac{d_i}{d_o}=-\frac{1}{d_o}\left(\frac{f_1 d_o}{d_o-f_1}\right)=-\frac{f_1}{d_o-f_1}\approx \boxed{-\frac{f_1}{d_o}}$$

This real image, located near the focal distance from lens 1, becomes the object for the second lens. We subtract the focal length from the separation distance to determine the object distance for lens 2. Using Eq. 32-2, we calculate the second image distance and Eq. 32-3 to calculate the second magnification. Multiplying the two magnifications gives the total magnification.

$$\frac{1}{d_{o2}}+\frac{1}{d_{i2}}=\frac{1}{f_2} \quad \rightarrow \quad d_{i2}=\frac{f_2 d_{o2}}{d_{o2}-f_2}$$

$$m_2=-\frac{d_{i2}}{d_{o2}}=-\frac{1}{d_{o2}}\left(\frac{f_2 d_{o2}}{d_{o2}-f_2}\right)=-\frac{f_2}{d_{o2}-f_2}=-\frac{\left(-\frac{1}{2}f_1\right)}{\left(\frac{3}{4}f_1-f_1\right)-\left(-\frac{1}{2}f_1\right)}=2$$

$$m_1 m_2=\left(-\frac{f_1}{d_o}\right)(2)=\boxed{-\frac{2f_1}{d_o}}$$

(*b*) If the object is at infinity, the image from the first lens will form a focal length behind that lens. Subtracting this distance from the separation distance gives the object distance for the second lens. We use Eq. 32-2 to calculate the image distance from the second lens. Adding this distance to the separation distance between the lenses gives the distance the image is from the first lens.

$$\frac{1}{d_{o2}}+\frac{1}{d_{i2}}=\frac{1}{f_2} \quad \rightarrow \quad d_{i2}=\frac{f_2 d_{o2}}{d_{o2}-f_2}=\frac{\left(-\frac{1}{2}f_1\right)\left(\frac{3}{4}f_1-f_1\right)}{\left(\frac{3}{4}f_1-f_1\right)-\left(-\frac{1}{2}f_1\right)}=\tfrac{1}{2}f_1$$

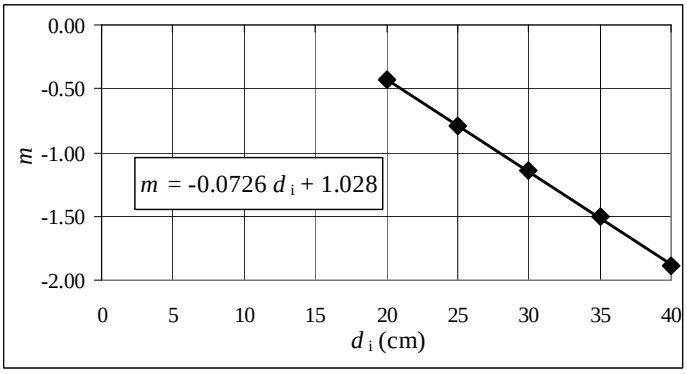
$$d=\ell+d_{i2}=\tfrac{3}{4}f_1+\tfrac{1}{2}f_1=\boxed{\tfrac{5}{4}f_1}$$

(*c*) We set the magnification equal to the total magnification found in part (*a*) and solve for the focal length.

$$m=-\frac{250\,\text{mm}}{d_o}=-\frac{2f_1}{d_o}\Rightarrow f_1=\frac{250\,\text{mm}}{2}=\boxed{125\,\text{mm}}$$

We use the results of part (*b*) to determine the distance of the lens to the film. We subtract this distance from 250 mm to determine how much closer the lens can be to the film in the two lens system.

$$d=\tfrac{5}{4}f_1=\tfrac{5}{4}(125\,\text{mm})=\boxed{156\,\text{mm}} \;;\; \Delta d=250\,\text{mm}-156\,\text{mm}=\boxed{94\,\text{mm}}$$



109. (*a*) We use Eqs. 33-2 and 33-3.

$$m=-\frac{d_i}{d_o} \quad \rightarrow \quad d_o=-\frac{d_i}{m} \;;\; \frac{1}{d_o}+\frac{1}{d_i}=\frac{1}{f}=-\frac{m}{d_i}+\frac{1}{d_i} \quad \rightarrow \quad m=-\frac{d_i}{f}+1$$

This is a straight line with $\boxed{\text{slope} = -\frac{1}{f} \text{ and } y\text{-intercept} = 1}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) A plot of m vs. d_i is shown here.

$$f = -\frac{1}{\text{slope}} = -\frac{1}{-.0726\,\text{cm}^{-1}}$$

$$= 13.8\,\text{cm} \approx \boxed{14\,\text{cm}}$$

The *y*-intercept is 1.028. Yes, it is close to the expected value of 1. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH33.XLS," on tab "Problem 33.109b."

(*c*) Use the relationship derived above.

$$m = -\frac{d_i}{f} + 1 = -\frac{d' + \ell_i}{f} + 1 = -\frac{d_i'}{f} + \left(1 - \frac{\ell_i}{f}\right)$$

A plot of m vs. d_i' would still have a slope of $-\frac{1}{f}$, so $f = \boxed{-\frac{1}{\text{slope}}}$ as before. The *y*-intercept will have changed, to $1 - \frac{\ell_i}{f}$.

CHAPTER 34: The Wave Nature of Light; Interference

Responses to Questions

1. Yes, Huygens' principle applies to all waves, including sound and water waves.

2. Light from the Sun can be focused by a converging lens on a piece of paper and burn a hole in the paper. This provides evidence that light is energy. Also, you can feel the heat from the Sun beating down on you on a hot summer day. When you move into the shade you may still feel hot, but you don't feel the Sun's energy directly.

3. A ray shows the direction of propagation of a wave front. If this information is enough for the situation under discussion, then light can be discussed as rays. Sometimes, however, the wave nature of light is essential to the discussion. For instance, the double slit interference pattern depends on the interference of the waves, and could not be explained by examining light as only rays.

4. The bending of waves around corners or obstacles is called diffraction. Diffraction is most prominent when the size of the obstacle is on the order of the size of the wavelength. Sound waves have much longer wavelengths than do light waves. As a result, the diffraction of sound waves around a corner is noticeable and we can hear the sound in the "shadow region," but the diffraction of light waves around a corner is not noticeable.

5. The wavelength of light cannot be determined from reflection measurements alone, because the law of reflection is the same for all wavelengths. However, thin film interference, which involves interference of the rays reflecting from the front and back surfaces of the film, can be used to determine wavelength. Refraction can also be used to determine wavelength because the index of refraction for a given medium is different for different wavelengths.

6. For destructive interference, the path lengths must differ by an odd number of half wavelengths, such as $\lambda/2$, $3\lambda/2$, $5\lambda/2$, $7\lambda/2$, etc. In general, the path lengths must differ by $\lambda(m + \frac{1}{2})$, where m is an integer.

7. Blue light has a shorter wavelength than red light. The angles to each of the bright fringes for the blue light would be smaller than for the corresponding orders for the red light, so the bright fringes would be closer together for the blue light.

8. The fringes would be closer together because the wavelength of the light underwater is less than the wavelength in air.

9. The two experiments are the same in principle. Each requires coherent sources and works best with a single frequency source. Each produces a pattern of alternating high and low intensity. Sound waves have much longer wavelengths than light waves, so the appropriate source separation for the sound experiment would be larger. Also, sound waves are mechanical waves which require a medium through which to travel, so the sound experiment could not be done in a vacuum and the light experiment could.

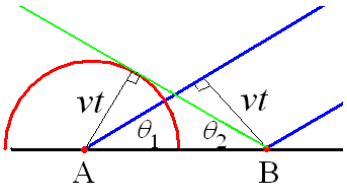
10. The red light and the blue light coming from the two different slits will have different wavelengths (and different frequencies) and will not have a constant phase relationship. In order for a double-slit pattern to be produced, the light coming from the slits must be coherent. No distinct double-slit interference pattern will appear. However, each slit will individually produce a "single-slit diffraction" pattern, as will be discussed in Chapter 35.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11. Light from the two headlights would not be coherent, so would not maintain a consistent phase relationship and therefore no stable interference pattern would be produced.

12. As the thickness of the film increases, the number of different wavelengths in the visible range that meet the constructive interference criteria increases. For a thick piece of glass, many different wavelengths will undergo constructive interference and these will all combine to produce white light.

13. Bright colored rings will occur when the path difference between the two interfering rays is λ/2, 3λ/2, 5λ/2, and so forth. A given ring, therefore, has a path difference that is exactly one wavelength longer than the path difference of its neighboring ring to the inside and one wavelength shorter than the path difference of its neighboring ring to the outside. Newton's rings are created by the thin film of air between a glass lens and the flat glass surface on which it is placed. Because the glass of the lens is curved, the thickness of this air film does not increase linearly. The farther a point is from the center, the less the horizontal distance that corresponds to an increase in vertical thickness of one wavelength. The horizontal distance between two neighboring rings therefore decreases with increasing distance from the center.



14. These lenses probably are designed to eliminate wavelengths at both the red and the blue ends of the spectrum. The thickness of the coating is designed to cause destructive interference for reflected red and blue light. The reflected light then appears yellow-green.

15. The index of refraction of the oil must be less than the index of refraction of the water. If the oil film appears bright at the edge, then the interference between the light reflected from the top of the oil film and from the bottom of the oil film at that point must be constructive. The light reflecting from the top surface (the air/oil interface) undergoes a 180º phase shift since the index of refraction of the oil is greater than that of air. The thickness of the oil film at the edge is negligible, so for there to be constructive interference, the light reflecting from the bottom of the oil film (the oil/water interface) must also undergo a 180º phase shift. This will occur only if the index of refraction of the oil is less than that of the water.

Solutions to Problems

1. Consider a wave front traveling at an angle θ_1 relative to a surface. At time $t = 0$, the wave front touches the surface at point A, as shown in the figure. After a time *t*, the wave front, moving at speed *v*, has moved forward such that the contact position has moved to point B. The distance between the two contact points is calculated using simple geometry: $\text{AB} = \dfrac{vt}{\sin\theta_1}$.

By Huygens' principle, at each point the wave front touches the surface, it creates a new wavelet. These wavelets expand out in all directions at speed *v*. The line passing through the surface of each of these wavelets is the reflected wave front. Using the radius of the wavelet created at $t = 0$, the center of the wavelet created at time *t*, and the distance between the two contact points (AB) we create a right triangle. Dividing the radius of the wavelet centered at AB (*vt*) by distance between the contact points gives the sine of the angle between the contact surface and the reflected wave, θ_2.

$$\sin\theta_2 = \frac{vt}{\text{AB}} = \frac{vt}{\dfrac{vt}{\sin\theta_1}} = \sin\theta_1 \quad \rightarrow \quad \boxed{\theta_2 = \theta_1}$$

Since these two angles are equal, their complementary angles (the incident and reflected angles) are also equal.

2. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. Apply this to the fifth order.

$$d\sin\theta = m\lambda \quad \rightarrow \quad \lambda = \frac{d\sin\theta}{m} = \frac{\left(1.8\times10^{-5}\,\text{m}\right)\sin 9.8^\circ}{5} = \boxed{6.1\times10^{-7}\,\text{m}}$$

3. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. Apply this to the third order.

$$d\sin\theta = m\lambda \quad \rightarrow \quad d = \frac{m\lambda}{\sin\theta} = \frac{3\left(610\times10^{-9}\,\text{m}\right)}{\sin 28^\circ} = \boxed{3.9\times10^{-6}\,\text{m}}$$

4. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell\tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$. Adjacent fringes will have $\Delta m = 1$.

$$d\sin\theta = m\lambda \quad \rightarrow \quad d\frac{x}{\ell} = m\lambda \quad \rightarrow \quad x = \frac{\lambda m\ell}{d}$$

$$x_1 = \frac{\lambda m_1\ell}{d} \;;\; x_2 = \frac{\lambda(m+1)\ell}{d} \quad \rightarrow \quad \Delta x = x_2 - x_1 = \frac{\lambda(m+1)\ell}{d} - \frac{\lambda m\ell}{d} = \frac{\lambda\ell}{d}$$

$$\lambda = \frac{d\Delta x}{\ell} = \frac{\left(4.8\times10^{-5}\,\text{m}\right)\left(0.085\,\text{m}\right)}{6.00\,\text{m}} = \boxed{6.8\times10^{-7}\,\text{m}} \;;\; f = \frac{c}{\lambda} = \frac{3.00\times10^8\,\text{m/s}}{6.8\times10^{-7}\,\text{m}} = \boxed{4.4\times10^{14}\,\text{Hz}}$$

5. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell\tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$. Second order means $m = 2$.

$$d\sin\theta = m\lambda \quad \rightarrow \quad d\frac{x}{\ell} = m\lambda \quad \rightarrow \quad x = \frac{\lambda m\ell}{d} \;;\; x_1 = \frac{\lambda_1 m\ell}{d} \;;\; x_2 = \frac{\lambda_2 m\ell}{d} \quad \rightarrow$$

$$\Delta x = x_2 - x_1 = \frac{(\lambda_2 - \lambda_1)m\ell}{d} = \frac{\left[(720-660)\times10^{-9}\,\text{m}\right](2)(1.0\,\text{m})}{\left(6.8\times10^{-4}\,\text{m}\right)} = 1.76\times10^{-4}\,\text{m} \approx \boxed{0.2\,\text{mm}}$$

This justifies using the small angle approximation, since $x \ll \ell$.

6. The slit spacing and the distance from the slits to the screen is the same in both cases. The distance between bright fringes can be taken as the position of the first bright fringe (m = 1) relative to the central fringe. We indicate the lab laser with subscript 1, and the laser pointer with subscript 2. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell\tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$.

$$d\sin\theta = m\lambda \quad \rightarrow \quad d\frac{x}{\ell} = m\lambda \quad \rightarrow \quad x = \frac{\lambda m\ell}{d} \;;\; x_1 = \frac{\lambda_1\ell}{d} \;;\; x_2 = \frac{\lambda_2\ell}{d} \quad \rightarrow$$

$$\lambda_2 = \frac{d}{\ell}x_2 = \frac{\lambda_1}{x_1}x_2 = \left(632.8\,\text{nm}\right)\frac{5.14\,\text{mm}}{5.00\,\text{mm}} = 650.52\,\text{nm} \approx \boxed{651\,\text{nm}}$$

7. Using a ruler on Fig. 35-9a, the distance from the $m = 0$ fringe to the $m = 10$ fringe is found to be about 13.5 mm. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell \tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$.

$$d\sin\theta = m\lambda \;\rightarrow\; d\frac{x}{\ell} = m\lambda \;\rightarrow\; \lambda = \frac{dx}{m\ell} = \frac{dx}{m\ell} = \frac{(1.7\times10^{-4}\,\text{m})(0.0135\,\text{m})}{(10)(0.35\,\text{m})} = \boxed{6.6\times10^{-7}\,\text{m}}$$

8. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell \tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$.

$$d\sin\theta = m\lambda \;\rightarrow\; d\frac{x}{\ell} = m\lambda \;\rightarrow\; d = \frac{\lambda m\ell}{x} = \frac{(680\times10^{-9}\,\text{m})(3)(2.6\,\text{m})}{38\times10^{-3}\,\text{m}} = \boxed{1.4\times10^{-4}\,\text{m}}$$

9. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell \tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$. For adjacent fringes, $\Delta m = 1$.

$$d\sin\theta = m\lambda \;\rightarrow\; d\frac{x}{\ell} = m\lambda \;\rightarrow\; x = \frac{\lambda m\ell}{d} \;\rightarrow$$

$$\Delta x = \Delta m\frac{\lambda\ell}{d} = (1)\frac{(633\times10^{-9}\,\text{m})(3.8\,\text{m})}{(6.8\times10^{-5}\,\text{m})} = 0.035\,\text{m} = \boxed{3.5\,\text{cm}}$$

10. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell \tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$.

$$d\sin\theta = m\lambda \;\rightarrow\; d\frac{x}{\ell} = m\lambda \;\rightarrow\; d = \frac{\lambda m\ell}{x} = \frac{(633\times10^{-9}\,\text{m})(1)(5.0\,\text{m})}{(0.25\,\text{m})} = \boxed{1.3\times10^{-5}\,\text{m}}$$

11. The 180° phase shift produced by the glass is equivalent to a path length of $\frac{1}{2}\lambda$. For constructive interference on the screen, the total path difference is a multiple of the wavelength:

$$\tfrac{1}{2}\lambda + d\sin\theta_{\max} = m\lambda,\; m = 0, 1, 2, \cdots \;\rightarrow\; d\sin\theta_{\max} = \left(m - \tfrac{1}{2}\right)\lambda,\; m = 1, 2, \cdots$$

We could express the result as $d\sin\theta_{\max} = \left(m + \tfrac{1}{2}\right)\lambda,\; m = 0, 1, 2, \cdots$.

For destructive interference on the screen, the total path difference is

$$\tfrac{1}{2}\lambda + d\sin\theta_{\min} = \left(m + \tfrac{1}{2}\right)\lambda,\; m = 0, 1, 2, \cdots \;\rightarrow\; d\sin\theta_{\min} = m\lambda,\; m = 0, 1, 2, \cdots$$

Thus the pattern is just the reverse of the usual double-slit pattern. There will be a dark central line. Every place there was a bright fringe will now have a dark line, and vice versa.

12. We equate the expression from Eq. 34-2a for the second order blue light to Eq. 34-2b, since the slit separation and angle must be the same for the two conditions to be met at the same location.

$$d\sin\theta = m\lambda_b = (2)(480\,\text{nm}) = 960\,\text{nm} \;;\; d\sin\theta = \left(m' + \tfrac{1}{2}\right)\lambda,\; m' = 0, 1, 2, \cdots$$

$$\left(m' + \tfrac{1}{2}\right)\lambda = 960\,\text{nm} \quad m' = 0 \;\rightarrow\; \lambda = 1920\,\text{nm} \;;\; m' = 1 \;\rightarrow\; \lambda = 640\,\text{nm}$$

$$m' = 2 \;\rightarrow\; \lambda = 384\,\text{nm}$$

The only one visible is 640 nm. 384 nm is near the low-wavelength limit for visible light.

13. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell \tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$. For adjacent fringes, $\Delta m = 1$.

$$d\sin\theta = m\lambda \;\rightarrow\; d\frac{x}{\ell} = m\lambda \;\rightarrow\; x = \frac{\lambda m \ell}{d} \;\rightarrow$$

$$\Delta x = \Delta m\frac{\lambda\ell}{d} = (1)\frac{\left(544\times10^{-9}\,\text{m}\right)\left(5.0\,\text{m}\right)}{\left(1.0\times10^{-3}\,\text{m}\right)} = \boxed{2.7\times10^{-3}\,\text{m}}$$

14. An expression is derived for the slit separation from the data for the 500 nm light. That expression is then used to find the location of the maxima for the 650 nm light. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell \tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$.

$$d\sin\theta = m\lambda \;\rightarrow\; d\frac{x}{\ell} = m\lambda \;\rightarrow\; d = \frac{\lambda m\ell}{x} = \frac{\lambda_1 m_1 \ell}{x_1} \;\rightarrow\; x = \frac{\lambda m\ell}{d} \;\rightarrow$$

$$x_2 = \frac{\lambda_2 m_2 \ell}{\dfrac{\lambda_1 m_1 \ell}{x_1}} = x_1\frac{\lambda_2 m_2}{\lambda_1 m_1} = (12\,\text{mm})\frac{(650\,\text{nm})(2)}{(500\,\text{nm})(3)} = 10.4\,\text{mm} \approx \boxed{10\,\text{mm}} \;\; (2\text{ sig. fig.})$$

15. The presence of the water changes the wavelength according to Eq. 34-1, and so we must change λ to $\lambda_n = \lambda/n$. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell \tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$. Adjacent fringes will have $\Delta m = 1$.

$$d\sin\theta = m\lambda_n \;\rightarrow\; d\frac{x}{\ell} = m\lambda_n \;\rightarrow\; x = \frac{\lambda_n m\ell}{d} \;;\; x_1 = \frac{\lambda m_1 \ell}{d} \;;\; x_2 = \frac{\lambda(m+1)\ell}{d} \;\rightarrow$$

$$\Delta x = x_2 - x_1 = \frac{\lambda_n(m+1)\ell}{d} - \frac{\lambda_n m\ell}{d} = \frac{\lambda_n\ell}{d} = \frac{\lambda\ell}{nd} = \frac{\left(470\times10^{-9}\,\text{m}\right)\left(0.500\,\text{m}\right)}{(1.33)\left(6.00\times10^{-5}\,\text{m}\right)} = \boxed{2.94\times10^{-3}\,\text{m}}$$

16. To change the center point from constructive interference to destructive interference, the phase shift produced by the introduction of the plastic must be equivalent to half a wavelength. The wavelength of the light is shorter in the plastic than in the air, so the number of wavelengths in the plastic must be ½ greater than the number in the same thickness of air. The number of wavelengths in the distance equal to the thickness of the plate is the thickness of the plate divided by the appropriate wavelength.

$$N_{\text{plastic}} - N_{\text{air}} = \frac{t}{\lambda_{\text{plastic}}} - \frac{t}{\lambda} = \frac{tn_{\text{plastic}}}{\lambda} - \frac{t}{\lambda} = \frac{t}{\lambda}\left(n_{\text{plastic}} - 1\right) = \tfrac{1}{2} \;\rightarrow$$

$$t = \frac{\lambda}{2\left(n_{\text{plastic}} - 1\right)} = \frac{680\,\text{nm}}{2(1.60-1)} = \boxed{570\,\text{nm}}$$

17. The intensity is proportional to the square of the amplitude. Let the amplitude at the center due to one slit be E_0. The amplitude at the center with both slits uncovered is $2E_0$.

$$\frac{I_{1\text{ slit}}}{I_{2\text{ slits}}} = \left(\frac{E_0}{2E_0}\right)^2 = \boxed{\frac{1}{4}}$$

Thus the amplitude due to a single slit is one-fourth the amplitude when both slits are open.

18. The intensity as a function of angle from the central maximum is given by Eq. 34-6.

$$I_\theta = I_0\cos^2\left(\frac{\pi d\sin\theta}{\lambda}\right) = \tfrac{1}{2}I_0 \;\rightarrow\; \cos^2\left(\frac{\pi d\sin\theta}{\lambda}\right) = \tfrac{1}{2} \;\rightarrow\; \cos\left(\frac{\pi d\sin\theta}{\lambda}\right) = \pm\frac{1}{\sqrt{2}}$$

$$\cos\left(\frac{\pi d\sin\theta}{\lambda}\right) = \pm\frac{1}{\sqrt{2}} \;\rightarrow\; \frac{\pi d\sin\theta}{\lambda} = \cos^{-1}\left(\pm\frac{1}{\sqrt{2}}\right) = 45°\pm n(90°) = \frac{\pi}{4}\pm n\frac{\pi}{2} \;\rightarrow$$

$$2d\sin\theta = \left(\tfrac{1}{2}\pm n\right)\lambda$$

To only consider $\theta \geq 0$, we take just the plus sign.

$$\boxed{2d\sin\theta = \left(n+\tfrac{1}{2}\right)\lambda,\ n = 0, 1, 2, \cdots}$$

19. The intensity of the pattern is given by Eq. 34-6. We find the angle where the intensity is half its maximum value.

$$I_\theta = I_0\cos^2\left(\frac{\pi d\sin\theta}{\lambda}\right) = \tfrac{1}{2}I_0 \;\rightarrow\; \cos^2\left(\frac{\pi d\sin\theta_{1/2}}{\lambda}\right) = \tfrac{1}{2} \;\rightarrow\; \cos\left(\frac{\pi d\sin\theta_{1/2}}{\lambda}\right) = \frac{1}{\sqrt{2}} \;\rightarrow$$

$$\frac{\pi d\sin\theta_{1/2}}{\lambda} = \cos^{-1}\frac{1}{\sqrt{2}} = \frac{\pi}{4} \;\rightarrow\; \sin\theta_{1/2} = \frac{\lambda}{4d}$$

If $\lambda \ll d$, then $\sin\theta = \dfrac{\lambda}{4d} \ll 1$ and so $\sin\theta \approx \theta$. This is the angle from the central maximum to the location of half intensity. The angular displacement from the half-intensity position on one side of the central maximum to the half-intensity position on the other side would be twice this.

$$\Delta\theta = 2\theta_{1/2} = 2\frac{\lambda}{4d} = \boxed{\frac{\lambda}{2d}}$$

20. (*a*) The phase difference is given in Eq. 34-4. We are given the path length difference, $d\sin\theta$.

$$\frac{\delta}{2\pi} = \frac{d\sin\theta}{\lambda} \;\rightarrow\; \delta = 2\pi\frac{1.25\lambda}{\lambda} = \boxed{2.50\pi}$$

(*b*) The intensity is given by Eq. 34-6.

$$I = I_0\cos^2\left(\frac{\delta}{2}\right) = I_0\cos^2(1.25\pi) = \boxed{0.500I_0}$$

21. A doubling of the intensity means that the electric field amplitude has increased by a factor of $\sqrt{2}$. We set the amplitude of the electric field of one slit equal to E_0 and of the other equal to $\sqrt{2}E_0$. We use Eq. 34-3 to write each of the electric fields, where the phase difference, δ, is given by Eq. 34-4. Summing these two electric fields gives the total electric field.

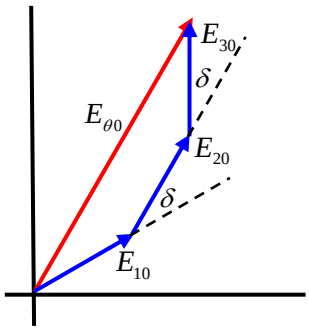
$$E_\theta = E_0\sin\omega t + \sqrt{2}E_0\sin(\omega t+\delta) = E_0\sin\omega t + \sqrt{2}E_0\sin\omega t\cos\delta + \sqrt{2}E_0\cos\omega t\sin\delta$$

$$= E_0\left(1+\sqrt{2}\cos\delta\right)\sin\omega t + \sqrt{2}E_0\cos\omega t\sin\delta$$

We square the total electric field intensity and integrate over the period to determine the average intensity.

$$\overline{E}_\theta^2 = \frac{1}{T}\int_0^T E_\theta^2 dt = \frac{1}{T}\int_0^T\left[E_0\left(1+\sqrt{2}\cos\delta\right)\sin\omega t + \sqrt{2}E_0\cos\omega t\sin\delta\right]^2 dt$$

$$= \frac{E_0^2}{T}\int_0^T\left[\left(1+\sqrt{2}\cos\delta\right)^2\sin^2\omega t + 2\cos^2\omega t\sin^2\delta + 2\sqrt{2}\left(1+\sqrt{2}\cos\delta\right)\sin\delta\sin\omega t\cos\omega t\right]dt$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

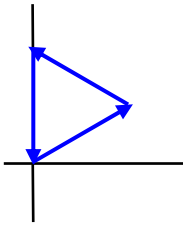
$$= \frac{E_0^2}{2}\left[\left(1+\sqrt{2}\cos\delta\right)^2 + 2\sin^2\delta\right] = \frac{E_0^2}{2}\left[3+2\sqrt{2}\cos\delta\right]$$

Since the intensity is proportional to this average square of the electric field, and the intensity is maximum when $\delta = 0$, we obtain the relative intensity by dividing the square of the electric field by the maximum square of the electric field.

$$\frac{I_\theta}{I_0} = \frac{\bar{E}_\theta^2}{E_{\delta=0}^2} = \boxed{\frac{3+2\sqrt{2}\cos\delta}{3+2\sqrt{2}}, \text{ with } \delta = \frac{2\pi}{\lambda} d\sin\theta}$$

22. (*a*) If the sources have equal intensities, their electric fields will have the same magnitudes. We show a phasor diagram with each of the electric fields shifted by an angle δ. As shown in the sketch, the three electric fields and their sum form a symmetric trapezoid. Since E_{20} and $E_{\theta 0}$ are parallel, and E_{20} is rotated from E_{10} and E_{30} by the angle δ, the magnitude of $E_{\theta 0}$ is the sum of the components of E_{10}, E_{20}, and E_{30} that are parallel to E_{20}.

$$E_{\theta 0} = E_{10}\cos\delta + E_{20} + E_{30}\cos\delta = E_{10}\left(1+2\cos\delta\right)$$



We set the intensity proportional to the square of the electric field magnitude and divide by the maximum intensity (at $\delta = 0$) to determine the relative intensity.

$$\frac{I_\theta}{I_0} = \frac{E_{\theta 0}^2}{E_{\delta=0}^2} = \frac{\left[E_{10}\left(1+2\cos\delta\right)\right]^2}{\left[E_{10}\left(1+2\cos 0\right)\right]^2} = \boxed{\frac{\left(1+2\cos\delta\right)^2}{9}, \ \delta = \frac{2\pi}{\lambda} d\sin\theta}$$

(*b*) The intensity will be at its maximum when $\cos\delta = 1$. In this case the three phasors are all in line.

$$\cos\delta_{\max} = 1 \ \rightarrow \ \delta_{\max} = 2m\pi = \frac{2\pi}{\lambda} d\sin\theta_{\max} \ \rightarrow \ \boxed{\sin\theta_{\max} = \frac{m\lambda}{d}, \quad m = 0, 1, 2, \cdots}$$

The intensity will be a minimum when $1+2\cos\delta = 0$. In this case the three phasors add to 0 and form an equilateral triangle as shown in the second diagram, for the case of $k = 1$, where k is defined below.

$$1+2\cos\delta_{\min} = 0 \ \rightarrow$$

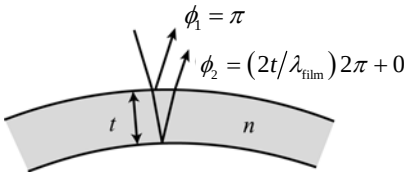
$$\delta_{\min} = \cos^{-1}\left(-\tfrac{1}{2}\right) = \begin{cases} \frac{2}{3}\pi + 2m\pi = 2\pi\left(m+\frac{1}{3}\right) \\ \frac{4}{3}\pi + 2m\pi = 2\pi\left(m+\frac{2}{3}\right) \end{cases}, \ m = 0, 1, 2, \cdots$$

This can be written as one expression with two parameters.

$$\delta_{\min} = 2\pi\left(m+\tfrac{1}{3}k\right) = \frac{2\pi}{\lambda} d\sin\theta_{\min}, \ k = 1, 2; \ m = 0, 1, 2, \cdots \ \rightarrow$$

$$\boxed{\sin\theta_{\min} = \frac{\lambda}{d}\left(m+\tfrac{1}{3}k\right) = , \ k = 1, 2; \ m = 0, 1, 2, \cdots}$$

23. From Example 34-7, we see that the thickness is related to the bright color wavelength by $t = \lambda/4n$.



$$t = \lambda/4n \ \rightarrow \ \lambda = 4nt = 4(1.32)(120\,\text{nm}) = \boxed{634\,\text{nm}}$$

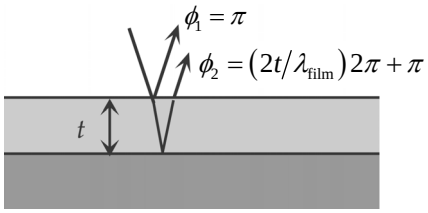
24. Between the 25 dark lines there are 24 intervals. When we add the half-interval at the wire end, we have 24.5 intervals over the length of the plates.

$$\frac{28.5\,\text{cm}}{24.5\,\text{intervals}} = \boxed{1.16\,\text{cm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

25. (*a*) An incident wave that reflects from the outer surface of the bubble has a phase change of $\phi_1 = \pi$. An incident wave that reflects from the inner surface of the bubble has a phase change due to the additional path length, so $\phi_2 = \left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi$. For destructive interference with a minimum non-zero thickness of bubble, the net phase change must be π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi\right] - \pi = \pi \quad \rightarrow \quad t = \tfrac{1}{2}\lambda_{\text{film}} = \frac{\lambda}{2n} = \frac{480\,\text{nm}}{2(1.33)} = \boxed{180\,\text{nm}}$$



(*b*) For the next two larger thicknesses, the net phase change would be 3π and 5π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi\right] - \pi = 3\pi \quad \rightarrow \quad t = \lambda_{\text{film}} = \frac{\lambda}{n} = \frac{480\,\text{nm}}{(1.33)} = \boxed{361\,\text{nm}}$$

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi\right] - \pi = 5\pi \quad \rightarrow \quad t = \lambda_{\text{film}} = \frac{\lambda}{n} = \tfrac{3}{2}\frac{480\,\text{nm}}{(1.33)} = \boxed{541\,\text{nm}}$$

(*c*) If the thickness were much less than one wavelength, then there would be very little phase change introduced by additional path length, and so the two reflected waves would have a phase difference of about $\phi_1 = \pi$. This would produce destructive interference.

26. An incident wave that reflects from the top surface of the coating has a phase change of $\phi_1 = \pi$. An incident wave that reflects from the glass $(n \approx 1.5)$ at the bottom surface of the coating has a phase change due to both the additional path length and a phase change of π on reflection, so $\phi_2 = \left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi + \pi$. For constructive interference with a minimum non-zero thickness of coating, the net phase change must be 2π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi + \pi\right] - \pi = 2\pi \quad \rightarrow \quad t = \tfrac{1}{2}\lambda_{\text{film}} = \tfrac{1}{2}\left(\frac{\lambda}{n_{\text{film}}}\right).$$

The lens reflects the most for $\lambda = 570\,\text{nm}$. The minimum non-zero thickness occurs for $m = 1$:

$$t_{\text{min}} = \frac{\lambda}{2n_{\text{film}}} = \frac{(570\,\text{nm})}{2(1.25)} = \boxed{228\,\text{nm}}$$

Since the middle of the spectrum is being selectively reflected, the transmitted light will be stronger in the red and blue portions of the visible spectrum.

27. (*a*) When illuminated from above at A, a light ray reflected from the air-oil interface undergoes a phase shift of $\phi_1 = \pi$. A ray reflected at the oil-water interface undergoes no phase shift. If the oil thickness at A is negligible compared to the wavelength of the light, then there is no significant shift in phase due to a path distance traveled by a ray in the oil. Thus the light reflected from the two surfaces will destructively interfere for all visible wavelengths, and the oil will appear black when viewed from above.

(*b*) From the discussion in part (*a*), the ray reflected from the air-oil interface undergoes a phase shift of $\phi_1 = \pi$. A ray that reflects from the oil-water interface has no phase change due to

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

reflection, but has a phase change due to the additional path length of $\phi_2 = \left(\frac{2t}{\lambda_{\text{oil}}}\right)2\pi$. For constructive interference, the net phase change must be a multiple of 2π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{\text{oil}}}\right)2\pi\right] - \pi = m(2\pi) \quad \rightarrow \quad t = \tfrac{1}{2}\left(m+\tfrac{1}{2}\right)\lambda_{\text{oil}} = \tfrac{1}{2}\left(m+\tfrac{1}{2}\right)\frac{\lambda}{n_{\text{o}}}$$

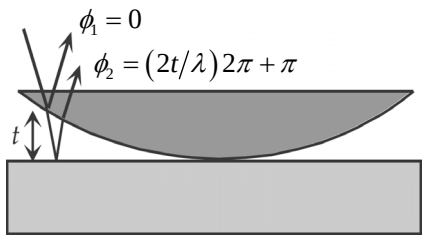
From the diagram, we see that point B is the second thickness that yields constructive interference for 580 nm, and so we use $m = 1$. (The first location that yields constructive interference would be for $m = 0$.)

$$t = \tfrac{1}{2}\left(m+\tfrac{1}{2}\right)\frac{\lambda}{n_{\text{o}}} = \tfrac{1}{2}\left(1+\tfrac{1}{2}\right)\frac{580\,\text{nm}}{1.50} = \boxed{290\,\text{nm}}$$

28. When illuminated from above, the light ray reflected from the air-oil interface undergoes a phase shift of $\phi_1 = \pi$. A ray reflected at the oil-water interface undergoes no phase shift due to reflection, but has a phase change due to the additional path length of $\phi_2 = \left(\frac{2t}{\lambda_{\text{oil}}}\right)2\pi$. For constructive interference to occur, the net phase change must be a multiple of 2π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{\text{oil}}}\right)2\pi\right] - \pi = m(2\pi) \quad \rightarrow \quad t = \tfrac{1}{2}\left(m+\tfrac{1}{2}\right)\lambda_{\text{oil}} = \tfrac{1}{2}\left(m+\tfrac{1}{2}\right)\frac{\lambda}{n_{\text{o}}}$$

For $\lambda = 650\,\text{nm}$, the possible thicknesses are as follows.



$$t_{650} = \tfrac{1}{2}\left(m+\tfrac{1}{2}\right)\frac{650\,\text{nm}}{1.50} = 108\,\text{nm},\ 325\,\text{nm},\ 542\,\text{nm},\ \cdots$$

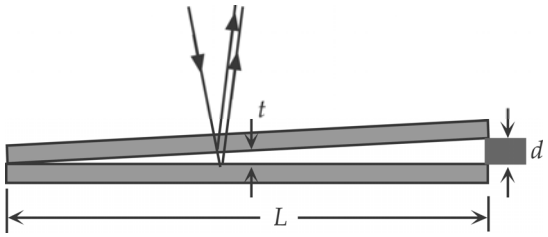
For $\lambda = 390\,\text{nm}$, the possible thicknesses are as follows.

$$t_{390} = \tfrac{1}{2}\left(m+\tfrac{1}{2}\right)\frac{390\,\text{nm}}{1.50} = 65\,\text{nm},\ 195\,\text{nm},\ 325\,\text{nm},\ 455\,\text{nm},\ \cdots$$

The minimum thickness of the oil slick must be $\boxed{325\,\text{nm}}$.

29. An incident wave that reflects from the convex surface of the lens has no phase change, so $\phi_1 = 0$. An incident wave that reflects from the glass underneath the lens has a phase change due to both the additional path length and a phase change of π on reflection, so $\phi_2 = \left(\frac{2t}{\lambda}\right)2\pi + \pi$. For destructive interference (dark rings), the net phase change must be an odd-integer multiple of π, so

$\phi_{\text{net}} = \phi_2 - \phi_1 = (2m+1)\pi,\ m = 0, 1, 2, \cdots$. Because $m = 0$ corresponds to the dark center, m represents the number of the ring.



$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda}\right)2\pi + \pi\right] - 0 = (2m+1)\pi,\ m = 0, 1, 2, \cdots \quad \rightarrow$$

$$t = \tfrac{1}{2}m\lambda_{\text{air}} = \tfrac{1}{2}(31)(560\,\text{nm}) = 8680\,\text{nm} = \boxed{8.68\,\mu\text{m}}$$

The thickness of the lens is the thickness of the air at the edge of the lens:

30. An incident wave that reflects from the second surface of the upper piece of glass has no phase change, so $\phi_1 = 0$. An incident wave that reflects from the first surface of the second piece of glass has a phase change due to both the additional path length and a phase change of π on reflection, so $\phi_2 = \left(\frac{2t}{\lambda}\right)2\pi + \pi$. For destructive interference (dark lines), the net phase change must be an odd-integer multiple of π, so $\phi_{\text{net}} = \phi_2 - \phi_1 = (2m+1)\pi,\ m = 0, 1, 2, \cdots$. Because $m = 0$ corresponds to the left edge of the diagram, the 28th dark line corresponds to $m = 27$. The 28th dark line also has a gap thickness of d.

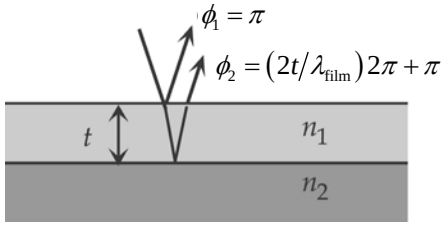
$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda}\right)2\pi + \pi\right] - 0 = (2m+1)\pi \ \rightarrow\ t = \tfrac{1}{2}m\lambda \ \rightarrow$$

$$d = \tfrac{1}{2}(27)(670\,\text{nm}) = 9045\,\text{nm} \approx \boxed{9.0\,\mu\text{m}}$$

31. With respect to the incident wave, the wave that reflects from the air at the top surface of the air layer has a phase change of $\phi_1 = 0$. With respect to the incident wave, the wave that reflects from the glass at the bottom surface of the air layer has a phase change due to both the additional path length and reflection, so $\phi_2 = \left(\frac{2t}{\lambda}\right)2\pi + \pi$. For constructive interference, the net phase change must be an even non-zero integer multiple of π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda}\right)2\pi + \pi\right] - 0 = 2m\pi \ \rightarrow\ t = \tfrac{1}{2}\left(m - \tfrac{1}{2}\right)\lambda,\ m = 1, 2, \cdots.$$

The minimum thickness is with $m = 1$.



$$t_{\text{min}} = \tfrac{1}{2}(450\,\text{nm})\left(1 - \tfrac{1}{2}\right) = \boxed{113\,\text{nm}}$$

For destructive interference, the net phase change must be an odd-integer multiple of π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda}\right)2\pi + \pi\right] - 0 = (2m+1)\pi \ \rightarrow\ t = \tfrac{1}{2}m\lambda,\ = 0, 1, 2, \cdots$$

The minimum non-zero thickness is $t_{\text{min}} = \tfrac{1}{2}(450\,\text{nm})(1) = \boxed{225\,\text{nm}}$.

32. With respect to the incident wave, the wave that reflects from the top surface of the alcohol has a phase change of $\phi_1 = \pi$. With respect to the incident wave, the wave that reflects from the glass at the bottom surface of the alcohol has a phase change due to both the additional path length and a phase change of π on reflection, so $\phi_2 = \left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi + \pi$. For constructive interference, the net phase change must be an even non-zero integer multiple of π.

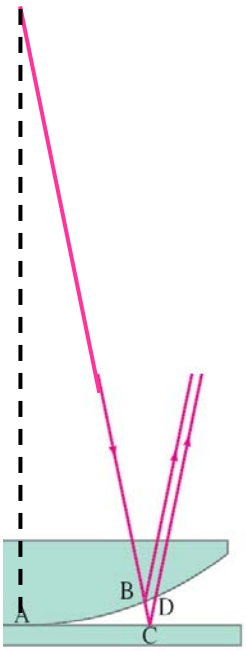
$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{1\text{film}}}\right)2\pi + \pi\right] - \pi = m_1 2\pi \ \rightarrow\ t = \tfrac{1}{2}\lambda_{1\text{film}}m_1 = \tfrac{1}{2}\frac{\lambda_1}{n_{\text{film}}}m_1,\ m_1 = 1, 2, 3, \ldots.$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

For destructive interference, the net phase change must be an odd-integer multiple π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{2\text{film}}}\right)2\pi + \pi\right] - \pi = (2m_2 + 1)\pi \quad \rightarrow \quad t = \tfrac{1}{4}\frac{\lambda_2}{n_{\text{film}}}(2m_2 + 1),\ m_2 = 0, 1, 2, \ldots.$$

Set the two expressions for the thickness equal to each other.



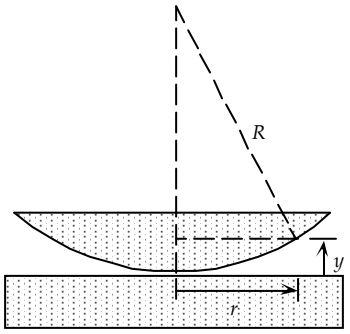
$$\tfrac{1}{2}\frac{\lambda_1}{n_{\text{film}}}m_1 = \tfrac{1}{4}\frac{\lambda_2}{n_{\text{film}}}(2m_2 + 1) \quad \rightarrow \quad \frac{2m_2 + 1}{2m_1} = \frac{\lambda_1}{\lambda_2} = \frac{(635\,\text{nm})}{(512\,\text{nm})} = 1.24 \approx 1.25 = \frac{5}{4}$$

Thus we see that $m_1 = m_2 = 2$, and the thickness of the film is

$$t = \tfrac{1}{2}\frac{\lambda_1}{n_{\text{film}}}m_1 = \tfrac{1}{2}\left(\frac{635\,\text{nm}}{1.36}\right)(2) = \boxed{467\,\text{nm}} \text{ or } t = \tfrac{1}{4}\frac{\lambda_2}{n_{\text{film}}}(2m_2 + 1) = \tfrac{1}{4}\left(\frac{512\,\text{nm}}{1.36}\right)(5) = \boxed{471\,\text{nm}}$$

With 2 sig.fig., the thickness is 470 nm. The range of answers is due to rounding λ_1/λ_2.

33. With respect to the incident wave, the wave that reflects from point B in the first diagram will not undergo a phase change, and so $\phi_B = 0$. With respect to the incident wave, the wave that reflects from point C in the first diagram has a phase change due to both the additional path length in air, and a phase change of π on reflection, and so we say that $\phi_D = \frac{2y}{\lambda}(2\pi) + \pi$, where y is the thickness of the air gap from B to C (or C to D). For dark rings, the net phase difference of the waves that recombine as they leave the glass moving upwards must be an odd-integer multiple of π.



$$\phi_{\text{net}} = \phi_D - \phi_B = \frac{2y}{\lambda}(2\pi) + \pi = (2m + 1)\pi \quad \rightarrow$$

$$y_{\text{dark}} = \tfrac{1}{2}m\lambda,\ m = 0, 1, 2, \cdots$$

Because $m = 0$ corresponds to the dark center, m represents the number of the dark ring.

Let the air gap of y be located a horizontal distance r from the center of the lens, as seen in the second diagram. Consider the dashed right triangle in the second diagram.

$$R^2 = r^2 + (R - y)^2 \quad \rightarrow$$

$$R^2 = r^2 + R^2 - 2Ry + y^2 \quad \rightarrow$$

$$r^2 = 2Ry - y^2$$

If we assume that $y \ll R$, then $r^2 \approx 2Ry$.

$$r^2 = 2Ry \quad \rightarrow \quad r_{\text{dark}}^2 = 2Ry_{\text{dark}} = 2R(\tfrac{1}{2}m\lambda) \quad \rightarrow \quad \boxed{r_{\text{dark}} = \sqrt{m\lambda R},\ m = 0, 1, 2, \cdots}$$

34. From Problem 33, we have $r = \sqrt{m\lambda R} = (m\lambda R)^{1/2}$. To find the distance between adjacent rings, we assume $m >> 1 \quad \rightarrow \quad \Delta m = 1 \ll m$. Since $\Delta m \ll m$, $\Delta r \approx \frac{dr}{dm}\Delta m$.

$$r = (m\lambda R)^{1/2} \quad ; \quad \frac{dr}{dm} = \tfrac{1}{2}(m\lambda R)^{-1/2}\lambda R$$

$$\Delta r \approx \frac{dr}{dm}\Delta m = \left[\tfrac{1}{2}(m\lambda R)^{-1/2}\lambda R\right](1) = \left[\frac{\lambda^2 R^2}{4m\lambda R}\right]^{1/2} = \boxed{\sqrt{\frac{\lambda R}{4m}}}$$

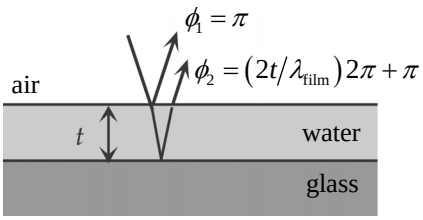
35. The radius of the *m*-th ring in terms of the wavelength of light and the radius of curvature is derived in Problem 33 as $r = \sqrt{m\lambda R}$. Using this equation, with the wavelength of light in the liquid given by Eq. 34-1, we divide the two radii and solve for the index of refraction.

$$\frac{r_{\text{air}}}{r_{\text{liquid}}} = \frac{\sqrt{m\lambda R}}{\sqrt{m(\lambda/n)R}} = \sqrt{n} \quad \rightarrow \quad n = \left(\frac{r_{\text{air}}}{r_{\text{liquid}}}\right)^2 = \left(\frac{2.92\text{ cm}}{2.54\text{ cm}}\right)^2 = \boxed{1.32}$$



36. We use the equation derived in Problem 33, where *r* is the radius of the lens (1.7 cm) to solve for the radius of curvature. Since the outer edge is the 44th bright ring, which would be halfway between the 44th and 45th dark fringes, we set *m*=44.5

$$r = \sqrt{m\lambda R} \quad \rightarrow \quad R = \frac{r^2}{m\lambda} = \frac{(0.017\text{ m})^2}{(44.5)(580\times10^{-9}\text{ m})} = 11.20\text{ m} \approx \boxed{11\text{m}}$$

We calculate the focal length of the lens using Eq. 33-4 (the lensmaker's equation) with the index of refraction of lucite taken from Table 32-1.

$$\frac{1}{f} = (n-1)\left(\frac{1}{R_1}+\frac{1}{R_2}\right) = (1.51-1)\left(\frac{1}{11.2\text{ m}}+\frac{1}{\infty}\right) = 0.0455\text{ m}^{-1} \quad \rightarrow \quad f = \frac{1}{0.0455\text{ m}^{-1}} = \boxed{22\text{ m}}$$

37. (*a*) Assume the indices of refraction for air, water, and glass are 1.00, 1.33, and 1.50, respectively. When illuminated from above, a ray reflected from the air-water interface undergoes a phase shift of $\phi_1 = \pi$, and a ray reflected at the water-glass interface also undergoes a phase shift of π. Thus, the two rays are unshifted in phase relative to each other due to reflection. For constructive interference, the path difference $2t$ must equal an integer number of wavelengths in water.

$$2t = m\lambda_{\text{water}} = m\frac{\lambda}{n_{\text{water}}},\ m = 0, 1, 2, \cdots \quad \rightarrow \quad \boxed{\lambda = \frac{2n_{\text{water}}t}{m}}$$

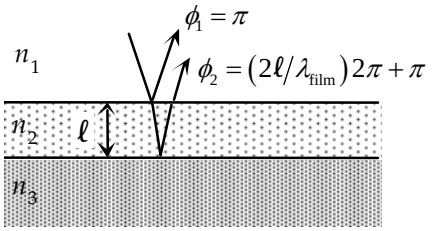
(*b*) The above relation can be solved for the *m*-value associated with the reflected color. If this *m*-value is an integer the wavelength undergoes constructive interference upon reflection.

$$\lambda = \frac{2n_{\text{water}}t}{m} \quad \rightarrow \quad m = \frac{2n_{\text{water}}t}{\lambda}$$

For a thickness $t = 200\mu\text{m} = 2\times10^5\text{ nm}$ the *m*-values for the two wavelengths are calculated.

$$m_{700\text{ nm}} = \frac{2n_{\text{water}}t}{\lambda} = \frac{2(1.33)(2\times10^5\text{ nm})}{700\text{ nm}} = 760$$

$$m_{400\text{ nm}} = \frac{2n_{\text{water}}t}{\lambda} = \frac{2(1.33)(2\times10^5\text{ nm})}{400\text{ nm}} = 1330$$



Since both wavelengths yield integers for m, they are both reflected.

(*c*) All *m*-values between *m* = 760 and *m* = 1330 will produce reflected visible colors. There are 1330 – (760 – 1) = $\boxed{571}$ such values.

(*d*) This mix of a large number of wavelengths from throughout the visible spectrum will give the thick layer a white or grey appearance.

38. We assume $n_1 < n_2 < n_3$ and that most of the incident light is transmitted. If the amplitude of an incident ray is taken to be E_0, then the amplitude of a reflected ray is rE_0, with $r << 1$. The light reflected from the top surface of the film therefore has an amplitude of rE_0 and is phase shifted by $\phi_1 = \pi$ from the incident wave, due to the higher index of refraction. The light transmitted at that top surface has an amplitude of $(1-r)E_0$. That light is then reflected off the bottom surface of the film, and we assume that it has the same reflection coefficient. Thus the amplitude of that second reflected ray is $r(1-r)E_0 = (r-r^2)E_0 \approx rE_0$, the same amplitude as the first reflected ray. Due to traveling through the film and reflecting from the glass, the second ray has a phase shift of $\phi_2 = \pi + 2\pi(2\ell/\lambda_{\text{film}}) = \pi + 4\pi\ell n_2/\lambda$, where ℓ is the thickness of the film. Summing the two reflected rays gives the net reflected wave.

$$E = rE_0\cos(\omega t + \pi) + rE_0\cos(\omega t + \pi + 4\pi\ell/\lambda_n)$$
$$= rE_0\left[(1+\cos 4\pi\ell n_2/\lambda)\cos(\omega t+\pi) - \sin(4\pi\ell n_2/\lambda)\sin(\omega t+\pi)\right]$$

As with the double slit experiment, we set the intensity proportional to the square of the wave amplitude and integrate over one period to calculate the average intensity.

$$I \propto \frac{1}{T}\int_0^T E^2 dt = \frac{1}{T}\int_0^T \left[rE_0\left[(1+\cos 4\pi\ell n_2/\lambda)\cos(\omega t+\pi) - \sin(4\pi\ell n_2/\lambda)\sin(\omega t+\pi)\right]\right]^2 dt$$
$$= \frac{r^2E_0^2}{T}\int_0^T \left[\begin{array}{l}(1+\cos 4\pi\ell n_2/\lambda)^2\cos^2(\omega t+\pi) + \sin^2(4\pi\ell n_2/\lambda)\sin^2(\omega t+\pi) \\ -2(1+\cos 4\pi\ell n_2/\lambda)\sin(4\pi\ell n_2/\lambda)\cos(\omega t+\pi)\sin(\omega t+\pi)\end{array}\right] dt$$
$$= \frac{r^2E_0^2}{2}\left[(1+\cos 4\pi\ell n_2/\lambda)^2 + \sin^2(4\pi\ell n_2/\lambda)\right] = r^2E_0^2(1+\cos 4\pi\ell n_2/\lambda)$$

The reflected intensity without the film is proportional to the square of the intensity of the single reflected electric field.

$$I_0 \propto \frac{1}{T}\int_0^T E_{\text{no film}}^2 dt = \frac{1}{T}\int_0^T \left[rE_0\cos(\omega t+\pi)\right]^2 dt = \frac{r^2E_0^2}{T}\int_0^T \left[\cos^2(\omega t+\pi)\right]dt = \frac{r^2E_0^2}{2}$$

Dividing the intensity with the film to that without the film gives the factor by which the intensity is reduced.

$$\frac{I}{I_0} = \frac{r^2E_0^2(1+\cos 4\pi\ell n_2/\lambda)}{\frac{1}{2}r^2E_0^2} = 2(1+\cos 4\pi\ell n_2/\lambda)$$

To determine the thickness of the film, the phase difference between the two reflected waves with $\lambda = 550\,\text{nm}$ must be an odd integer multiple of π so that there is destructive interference. The minimum thickness will be for *m* = 0.

$$\phi_2 - \phi_1 = [\pi + 4\pi\ell n_2/\lambda] - \pi = (2m+1)\pi \;\rightarrow\; \ell = \frac{\lambda_n}{4} = \frac{\lambda}{4n} = \frac{550\,\text{nm}}{4n}$$

It is interesting to see that the same result is obtained if we set the reflected intensity equal to zero for a wavelength of 550 nm.

$$\frac{I}{I_0} = 2(1+\cos 4\pi\ell n_2/\lambda) = 0 \;\rightarrow\; \cos 4\pi\ell n_2/\lambda = -1 \;\rightarrow\; 4\pi\ell n_2/\lambda = \pi \;\rightarrow\; \ell = \frac{550\,\text{nm}}{4n}$$

Finally, we insert the two given wavelengths (430 nm and 670 nm) into the intensity equation to determine the reduction in intensities.

$$\text{For } \lambda = 430 \text{ nm}, \quad \frac{I}{I_0} = 2\left(1+\cos 4\pi \frac{550 \text{ nm}/4n}{430 \text{ nm}/n}\right) = 2\left(1+\cos 4\pi \frac{550 \text{ nm}}{4(430 \text{ nm})}\right) = 0.721 \approx \boxed{72\%}$$

$$\text{For } \lambda = 670 \text{ nm}, \quad \frac{I}{I_0} = 2\left(1+\cos 4\pi \frac{550 \text{ nm}}{4(670 \text{ nm})}\right) = 0.308 \approx \boxed{31\%}$$

39. From the discussion in section 34-6, we see that the path length change is twice the distance that the mirror moves. One fringe shift corresponds to a change in path length of λ, and so corresponds to a mirror motion of $\frac{1}{2}\lambda$. Let *N* be the number of fringe shifts produced by a mirror movement of Δx.

$$N = \frac{\Delta x}{\frac{1}{2}\lambda} \quad \rightarrow \quad \Delta x = \tfrac{1}{2} N\lambda = \tfrac{1}{2}(650)\left(589\times 10^{-9}\text{ m}\right) = \boxed{1.91\times 10^{-4}\text{ m}}$$

40. From the discussion in section 34-6, we see that the path length change is twice the distance that the mirror moves. One fringe shift corresponds to a change in path length of λ, and so corresponds to a mirror motion of $\frac{1}{2}\lambda$. Let *N* be the number of fringe shifts produced by a mirror movement of Δx.

$$N = \frac{\Delta x}{\frac{1}{2}\lambda} \quad \rightarrow \quad \lambda = \frac{2\Delta x}{N} = \frac{2\left(1.25\times 10^{-4}\text{ m}\right)}{384} = 6.51\times 10^{-7}\text{ m} = \boxed{651\text{nm}}$$

41. From the discussion in section 34-6, we see that the path length change is twice the distance that the mirror moves. One fringe shift corresponds to a change in path length of λ, and so corresponds to a mirror motion of $\frac{1}{2}\lambda$. Let *N* be the number of fringe shifts produced by a mirror movement of Δx. The thickness of the foil is the distance that the mirror moves during the 272 fringe shifts.

$$N = \frac{\Delta x}{\frac{1}{2}\lambda} \quad \rightarrow \quad \Delta x = \tfrac{1}{2} N\lambda = \tfrac{1}{2}(272)\left(589\times 10^{-9}\text{ m}\right) = \boxed{8.01\times 10^{-5}\text{ m}}$$

42. One fringe shift corresponds to an effective change in path length of λ. The actual distance has not changed, but the number of wavelengths in the depth of the cavity has. If the cavity has a length *d*, the number of wavelengths in vacuum is $\frac{d}{\lambda}$, and the (greater) number with the gas present is $\frac{d}{\lambda_{\text{gas}}} = \frac{n_{\text{gas}} d}{\lambda}$. Because the light passes through the cavity twice, the number of fringe shifts is twice the difference in the number of wavelengths in the two media.

$$N = 2\left(\frac{n_{\text{gas}} d}{\lambda} - \frac{d}{\lambda}\right) = 2\frac{d}{\lambda}\left(n_{\text{gas}} - 1\right) \quad \rightarrow \quad n_{\text{gas}} = \frac{N\lambda}{2d} + 1 = \frac{(176)\left(632.8\times 10^{-9}\text{ m}\right)}{2\left(1.155\times 10^{-2}\text{ m}\right)} + 1 = \boxed{1.00482}$$

43. There are two interference patterns formed, one by each of the two wavelengths. The fringe patterns overlap but do not interfere with each other. Accordingly, when the bright fringes of one pattern occurs at the same locations as the dark fringes of the other patterns, there will be no fringes seen, since there will be no dark bands to distinguish one fringe from the adjacent fringes.

To shift from one "no fringes" occurrence to the next, the mirror motion must produce an integer number of fringe shifts for each wavelength, and the number of shifts for the shorter wavelength must be one more than the number for the longer wavelength. From the discussion in section 34-6, we see that the path length change is twice the distance that the mirror moves. One fringe shift

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

corresponds to a change in path length of λ, and so corresponds to a mirror motion of $\frac{1}{2}\lambda$. Let N be the number of fringe shifts produced by a mirror movement of Δx.

$$N_1 = 2\frac{\Delta x}{\lambda_1} \;;\; N_2 = 2\frac{\Delta x}{\lambda_2} \;;\; N_2 = N_1 + 1 \;\rightarrow\; 2\frac{\Delta x}{\lambda_2} = 2\frac{\Delta x}{\lambda_1} + 1 \;\rightarrow$$

$$\Delta x = \frac{\lambda_1\lambda_2}{2(\lambda_1 - \lambda_2)} = \frac{(589.6\,\text{nm})(589.0\,\text{nm})}{2(0.6\,\text{nm})} = 2.89\times10^5\,\text{nm} \approx \boxed{2.9\times10^{-4}\,\text{m}}$$

44. We assume the luminous flux is uniform, and so is the same in all directions.

$$F_\ell = E_\ell A = E_\ell 4\pi r^2 = \left(10^5\,\text{lm/m}^2\right)4\pi\left(1.496\times10^{11}\,\text{m}\right)^2 = 2.81\times10^{28}\,\text{lm} \approx \boxed{3\times10^{28}\,\text{lm}}$$

$$I_\ell = \frac{F_\ell}{4\pi\,\text{sr}} = \frac{2.81\times10^{28}\,\text{lm}}{4\pi\,\text{sr}} = 2.24\times10^{27}\,\text{cd} \approx \boxed{2\times10^{27}\,\text{cd}}$$

45. (*a*) The wattage of the bulb is the electric power input to the bulb.

$$\text{luminous efficiency} = \frac{F_\ell}{P} = \frac{1700\,\text{lm}}{100\,\text{W}} = \boxed{17\,\text{lm/W}}$$

(*b*) The illuminance is the luminous flux incident on a surface, divided by the area of the surface. Let N represent the number of lamps, each contributing an identical amount of luminous flux.

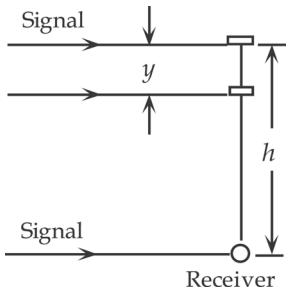
$$E_\ell = \frac{F_\ell}{A} = \frac{N\left[\frac{1}{2}(\text{luminous efficiency})P\right]}{A} \;\rightarrow$$

$$N = \frac{2E_\ell A}{(\text{luminous efficiency})P} = \frac{2\left(250\,\text{lm/m}^2\right)(25\,\text{m})(30\,\text{m})}{(60\,\text{lm/W})(40\,\text{W})} = 156\,\text{lamps} \approx \boxed{160\,\text{lamps}}$$

46. (*a*) For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell\tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$. For adjacent fringes, $\Delta m = 1$.

$$d\sin\theta = m\lambda \;\rightarrow\; d\frac{x}{\ell} = m\lambda \;\rightarrow\; x = \frac{\lambda m\ell}{d} \;\rightarrow\; \Delta x = \Delta m\frac{\lambda\ell}{d} \;\rightarrow$$

$$d = \frac{\lambda\ell\Delta m}{\Delta x} = \frac{\left(5.0\times10^{-7}\,\text{m}\right)(4.0\,\text{m})(1)}{\left(2.0\times10^{-2}\,\text{m}\right)} = \boxed{1.0\times10^{-4}\,\text{m}}$$



(*b*) For minima, we use Eq. 34-2b. The fourth-order minimum corresponds to $m = 3$, and the fifth-order minimum corresponds to $m = 4$. The slit separation, screen distance, and location on the screen are the same for the two wavelengths.

$$d\sin\theta = \left(m + \tfrac{1}{2}\right)\lambda \;\rightarrow\; d\frac{x}{\ell} = \left(m + \tfrac{1}{2}\right)\lambda \;\rightarrow\; \left(m_\text{A} + \tfrac{1}{2}\right)\lambda_\text{A} = \left(m_\text{B} + \tfrac{1}{2}\right)\lambda_\text{B} \;\rightarrow$$

$$\lambda_\text{B} = \lambda_\text{A}\frac{\left(m_\text{A} + \frac{1}{2}\right)}{\left(m_\text{B} + \frac{1}{2}\right)} = \left(5.0\times10^{-7}\,\text{m}\right)\frac{3.5}{4.5} = \boxed{3.9\times10^{-7}\,\text{m}}$$

47. The wavelength of the signal is $\lambda = \dfrac{v}{f} = \dfrac{\left(3.00\times10^8\ \text{m/s}\right)}{\left(75\times10^6\ \text{Hz}\right)} = 4.00\,\text{m}.$

(*a*) There is a phase difference between the direct and reflected signals from both the path difference, $\left(\dfrac{h}{\lambda}\right)2\pi$, and the reflection, π.

The total phase difference is the sum of the two.

$$\phi = \left(\frac{h}{\lambda}\right)2\pi + \pi = \frac{(122\,\text{m})}{(4.00\,\text{m})}2\pi + \pi = 62\pi = 31(2\pi)$$

Since the phase difference is an integer multiple of 2π, the interference is constructive.

(*b*) When the plane is 22 m closer to the receiver, the phase difference is as follows.

$$\phi = \left[\frac{(h-y)}{\lambda}\right]2\pi + \pi = \left[\frac{(122\,\text{m} - 22\,\text{m})}{(4.00\,\text{m})}\right]2\pi + \pi = 51\pi = \frac{51}{2}(2\pi)$$

Since the phase difference is an odd-half-integer multiple of 2π, the interference is destructive.

48. Because the measurements are made far from the antennas, we can use the analysis for the double slit. Use Eq. 34-2a for constructive interference, and 34-2b for destructive interference. The wavelength of the signal is $\lambda = \dfrac{v}{f} = \dfrac{\left(3.00\times10^8\,\text{m/s}\right)}{\left(88.5\times10^6\,\text{Hz}\right)} = 3.39\,\text{m}.$

For constructive interference, the path difference is a multiple of the wavelength:

$$d\sin\theta = m\lambda,\ m = 0, 1, 2, 3, \ldots; \quad \rightarrow \quad \theta = \sin^{-1}\frac{m\lambda}{d}$$

$$\theta_{1\ \text{max}} = \sin^{-1}\frac{(1)(3.39\,\text{m})}{9.0\,\text{m}} = \boxed{22°}\ ;\ \theta_{2\ \text{max}} = \sin^{-1}\frac{(2)(3.39\,\text{m})}{9.0\,\text{m}} = \boxed{49°}\ ;$$

$$\theta_{3\ \text{max}} = \sin^{-1}\frac{(3)(3.39\,\text{m})}{9.0\,\text{m}} = \text{impossible}$$

For destructive interference, the path difference is an odd multiple of half a wavelength:

$$d\sin\theta = \left(m+\tfrac{1}{2}\right)\lambda,\ m = 0, 1, 2, 3, \ldots; \quad \rightarrow \quad \theta = \sin^{-1}\frac{\left(m+\frac{1}{2}\right)\lambda}{d}$$

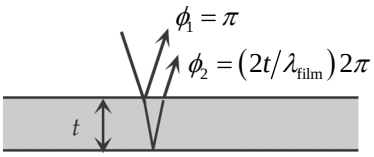
$$\theta_{0\ \text{max}} = \sin^{-1}\frac{\left(\frac{1}{2}\right)(3.39\,\text{m})}{9.0\,\text{m}} = \boxed{11°}\ ;\ \theta_{1\ \text{max}} = \sin^{-1}\frac{\left(\frac{3}{2}\right)(3.39\,\text{m})}{9.0\,\text{m}} = \boxed{34°}\ ;$$

$$\theta_{2\ \text{max}} = \sin^{-1}\frac{\left(\frac{5}{2}\right)(3.39\,\text{m})}{9.0\,\text{m}} = \boxed{70°}\ ;\ \theta_{3\ \text{max}} = \sin^{-1}\frac{\left(\frac{7}{2}\right)(3.39\,\text{m})}{9.0\,\text{m}} = \text{impossible}$$

These angles are applicable both above and below the midline, and both to the left and the right of the antennas.

49. For constructive interference, the path difference is a multiple of the wavelength, as given by Eq. 34-2a. The location on the screen is given by $x = \ell\tan\theta$, as seen in Fig. 34-7(c). For small angles, we have $\sin\theta \approx \tan\theta \approx x/\ell$. Second order means $m = 2$.

$$d\sin\theta = m\lambda \quad \rightarrow \quad d\frac{x}{\ell} = m\lambda \quad \rightarrow \quad x = \frac{\lambda m\ell}{d}\ ;\ x_1 = \frac{\lambda_1 m\ell}{d}\ ;\ x_2 = \frac{\lambda_2 m\ell}{d} \quad \rightarrow$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\Delta x = x_1 - x_2 = \frac{\lambda_1 m\ell}{d} - \frac{\lambda_2 m\ell}{d} \quad \rightarrow$$

$$\lambda_2 = \lambda_1 - \frac{d\,\Delta x}{m\ell} = 690\times10^{-9}\,\text{m} - \frac{\left(6.6\times10^{-4}\,\text{m}\right)\left(1.23\times10^{-3}\,\text{m}\right)}{2\left(1.60\,\text{m}\right)} = 4.36\times10^{-7}\,\text{m} \approx \boxed{440\,\text{nm}}$$

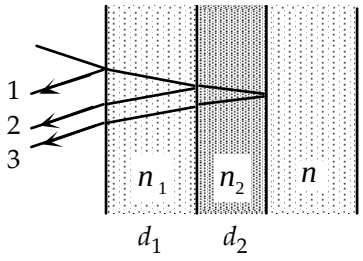
50. PLEASE NOTE: In early versions of the textbook, in which the third line of this problem states that "… light is a minimum only for …," the resulting answer does not work out properly. It yields values of $m = 6$ and $m = 4$ for the integers in the interference relationship. Accordingly, the problem was changed to read "… light is a maximum only for … ." The solution here reflects that change.

With respect to the incident wave, the wave that reflects at the top surface of the film has a phase change of $\phi_1 = \pi$. With respect to the incident wave, the wave that reflects from the bottom surface of the film has a phase change due to the additional path length and no phase change due to reflection, so $\phi_2 = \left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi + 0$. For constructive interference, the net phase change must be an integer multiple of 2π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi - \pi = 2\pi m \quad \rightarrow \quad t = \tfrac{1}{2}\left(m + \tfrac{1}{2}\right)\lambda_{\text{film}} = \tfrac{1}{2}\left(m + \tfrac{1}{2}\right)\frac{\lambda}{n_{\text{film}}},\ m = 0,\ 1,\ 2,\ \ldots.$$

Evaluate the thickness for the two wavelengths.

$$t = \tfrac{1}{2}\left(m_1 + \tfrac{1}{2}\right)\frac{\lambda_1}{n_{\text{film}}} = \tfrac{1}{2}\left(m_2 + \tfrac{1}{2}\right)\frac{\lambda_2}{n_{\text{film}}} \quad \rightarrow \quad \frac{\left(m_2 + \tfrac{1}{2}\right)}{\left(m_1 + \tfrac{1}{2}\right)} = \frac{\lambda_1}{\lambda_2} = \frac{688.0\,\text{nm}}{491.4\,\text{nm}} = 1.40 = \frac{7}{5}$$



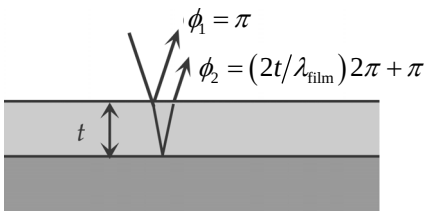
Thus $m_2 = 3$ and $m_1 = 2$. Evaluate the thickness with either value and the corresponding wavelength.

$$t = \tfrac{1}{2}\left(m_1 + \tfrac{1}{2}\right)\frac{\lambda_1}{n_{\text{film}}} = \tfrac{1}{2}\left(\tfrac{5}{2}\right)\frac{688.0\,\text{nm}}{1.58} = \boxed{544\,\text{nm}} \ ;\ t = \tfrac{1}{2}\left(m_2 + \tfrac{1}{2}\right)\frac{\lambda_2}{n_{\text{film}}} = \tfrac{1}{2}\left(\tfrac{7}{2}\right)\frac{491.4\,\text{nm}}{1.58} = \boxed{544\,\text{nm}}$$

51. From the discussion in section 34-6, we see that the path length change is twice the distance that the mirror moves. The phase shift is 2π for every wavelength of path length change. The intensity as a function of phase shift is given by Eq. 34-6.

$$\frac{\delta}{2\pi} = \frac{\text{path change}}{\lambda} = \frac{2x}{\lambda} \quad \rightarrow \quad \delta = \frac{4\pi x}{\lambda} \ ;\ I = I_0\cos^2\frac{\delta}{2} = \boxed{I_0\cos^2\left(\frac{2\pi x}{\lambda}\right)}$$

52. To maximize reflection, the three rays shown in the figure should be in phase. We first compare rays 2 and 3. Ray 2 reflects from $n_2 > n_1$, and so has a phase shift of $\phi_2 = \pi$. Ray 3 will have a phase change due to the additional path length in material 2, and a phase shift of π because of reflecting from $n > n_2$. Thus $\phi_3 = \left(\frac{2d_2}{\lambda_2}\right)2\pi + \pi$. For constructive interference the net phase change for rays 2 and 3 must be a non-zero integer multiple of 2π.



$$\Delta\phi_{2-3} = \phi_3 - \phi_2 = \left[\left(\frac{2d_2}{\lambda_2}\right)2\pi + \pi\right] - \pi = 2m\pi \quad \rightarrow \quad d_2 = \tfrac{1}{2}m\lambda_2,\ m = 1,\ 2,\ 3\cdots$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The minimum thickness is for $m = 1$, and so $d_2 = \frac{1}{2}m\lambda_2 = \boxed{\dfrac{\lambda}{2n_2}}$.

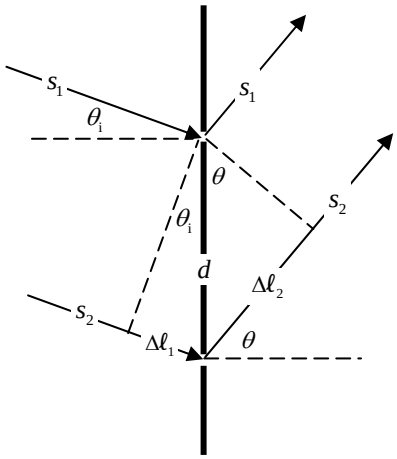
Now consider rays 1 and 2. The exact same analysis applies, because the same relationship exists between the indices of refraction: $n_1 > n$ and $n_2 > n_1$. Thus $d_1 = \boxed{\dfrac{\lambda}{2n_1}}$.

53. With respect to the incident wave, the wave that reflects from the top surface of the coating has a phase change of $\phi_1 = \pi$. With respect to the incident wave, the wave that reflects from the glass $(n \approx 1.5)$ at the bottom surface of the coating has a phase change due to both the additional path length and reflection, so $\phi_2 = \left(\dfrac{2t}{\lambda_{\text{film}}}\right)2\pi + \pi$. For destructive interference, the net phase change must be an odd-integer multiple of π.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi + \pi\right] - \pi = (2m+1)\pi \quad \rightarrow$$

$$t = \tfrac{1}{4}(2m+1)\lambda_{\text{film}} = \tfrac{1}{4}(2m+1)\frac{\lambda}{n_{\text{film}}},\ m = 0, 1, 2, \ldots$$

The minimum thickness has $m = 0$, and so $t_{\min} = \frac{1}{4}\dfrac{\lambda}{n_{\text{film}}}$.



(*a*) For the blue light: $t_{\min} = \frac{1}{4}\dfrac{(450\,\text{nm})}{(1.38)} = 81.52\,\text{nm} \approx \boxed{82\,\text{nm}}$.

(*b*) For the red light: $t_{\min} = \frac{1}{4}\dfrac{(700\,\text{nm})}{(1.38)} = 126.8\,\text{nm} \approx \boxed{130\,\text{nm}}$.

54. The phase difference caused by the path difference back and forth through the coating must correspond to half a wavelength in order to produce destructive interference.

$$2t = \tfrac{1}{2}\lambda \quad \rightarrow \quad t = \tfrac{1}{4}\lambda = \tfrac{1}{4}(2\,\text{cm}) = \boxed{0.5\,\text{cm}}$$

55. We consider a figure similar to Figure 34-12, but with the incoming rays at an angle of θ_i to the normal. Ray s_2 will travel an extra distance $\Delta\ell_1 = d\sin\theta_i$ before reaching the slits, and an extra distance $\Delta\ell_2 = d\sin\theta$ after leaving the slits. There will be a phase difference between the waves due to the path difference $\Delta\ell_1 + \Delta\ell_2$. When this total path difference is a multiple of the wavelength, constructive interference will occur.

$$\Delta\ell_1 + \Delta\ell_2 = d\sin\theta_i + d\sin\theta = m\lambda \quad \rightarrow$$

$$\sin\theta = \frac{m\lambda}{d} - \sin\theta_i, \quad m = 0, 1, 2, \cdots$$

Since the rays leave the slits at all angles in the forward direction, we could have drawn the leaving rays with a downward tilt instead of an upward tilt. This would make the ray s_2 traveling a longer distance from the slits to the screen. In

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

this case the path difference would be $\Delta\ell_2 - \Delta\ell_1$, and would result in the following expression.

$$\Delta\ell_2 - \Delta\ell_1 = d\sin\theta - d\sin\theta_i = m\lambda \quad \rightarrow \quad \sin\theta = \frac{m\lambda}{d} + \sin\theta_i, \quad m = 0, 1, 2, \cdots$$

$$\Delta\ell_1 - \Delta\ell_2 = d\sin\theta_i - d\sin\theta = m\lambda \quad \rightarrow \quad \sin\theta = -\frac{m\lambda}{d} + \sin\theta_i, \quad m = 0, 1, 2, \cdots$$

We combine the statements as follows.

$$\boxed{\sin\theta = \frac{m\lambda}{d} \pm \sin\theta_i, \quad m = 0, 1, 2, \cdots}$$

Because of an arbitrary choice of taking $\Delta\ell_2 - \Delta\ell_1$, we could also have formulated the problem so that the result would be expressed as $\boxed{\sin\theta = \sin\theta_i \pm \frac{m\lambda}{d}, \quad m = 0, 1, 2, \cdots}$.

56. The signals will be out of phase when the path difference equals an odd number of half-wavelengths. Let the 175-m distance be represented by *d*.

$$\sqrt{y^2 + d^2} - y = \left(m + \tfrac{1}{2}\right)\lambda,\ m = 0, 1, 2, 3, \ldots \quad \rightarrow \quad \sqrt{y^2 + d^2} = y + \left(m + \tfrac{1}{2}\right)\lambda \quad \rightarrow$$

$$y^2 + d^2 = y^2 + 2y\left(m + \tfrac{1}{2}\right)\lambda + \left(m + \tfrac{1}{2}\right)^2\lambda^2 \quad \rightarrow \quad y = \frac{d^2 - \left(m + \tfrac{1}{2}\right)^2\lambda^2}{2\left(m + \tfrac{1}{2}\right)\lambda}$$

We evaluate this for the first three values of *m*. The wavelength is $\lambda = \frac{c}{f} = \frac{3.00 \times 10^8\ \text{m/s}}{6.0 \times 10^6\ \text{Hz}} = 50\,\text{m}.$

$$y = \frac{d^2 - \left(m + \tfrac{1}{2}\right)^2\lambda^2}{2\left(m + \tfrac{1}{2}\right)\lambda} = \frac{(175\,\text{m})^2 - \left(m + \tfrac{1}{2}\right)^2(50\,\text{m})^2}{2\left(m + \tfrac{1}{2}\right)(50\,\text{m})} = 600\,\text{m}, 167\,\text{m}, 60\,\text{m}, 0\,\text{m}$$

The first three points on the *y* axis where the signals are out of phase are at $y = \boxed{0, 60\,\text{m, and } 167\,\text{m}}$.

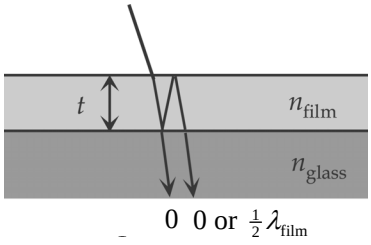
57. As explained in Example 34-6 the $\frac{1}{2}$-cycle phase change at the lower surface means that destructive interference occurs when the thickness *t* is such that $2t = m\lambda,\ m = 0, 1, 2, \ldots$. Set $m = 1$ to find the smallest nonzero value of *t*.

$$t = \tfrac{1}{2}\lambda = \tfrac{1}{2}(680\,\text{nm}) = \boxed{340\,\text{nm}}$$

As also explained in Example 34-6, constructive interference will occur when $2t = \left(m + \tfrac{1}{2}\right)\lambda$, $m = 0, 1, 2, \ldots$. We set $m = 0$ to find the smallest value of *t*:

$$t = \tfrac{1}{4}\lambda = \tfrac{1}{4}(680\,\text{nm}) = \boxed{170\,\text{nm}}$$

58. The reflected wave appears to be coming from the virtual image, so this corresponds to a double slit, with the separation being *d* = 2S. The reflection from the mirror produces a π phase shift, however, so the maxima and minima are interchanged, as described in Problem 11.



$$\sin\theta_{\max} = \left(m + \tfrac{1}{2}\right)\frac{\lambda}{2\text{S}},\ m = 0, 1, 2, \cdots \ ; \ \sin\theta_{\min} = m\frac{\lambda}{2\text{S}},\ m = 0, 1, 2, \cdots$$

59. Since the two sources are 180° out of phase, destructive interference will occur when the path length difference between the two sources and the receiver is 0, or an integer number of wavelengths. Since the antennae are separated by a distance of $d = \lambda/2$, the path length difference can never be greater than $\lambda/2$, so the only points of destructive interference occur when the receiver is equidistant from each antenna, that is, at $\boxed{\theta_{\text{destructive}} = 0° \text{ and } 180°}$. Constructive interference occurs when the path difference is a half integer wavelength. Again, since the separation distance between the two

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

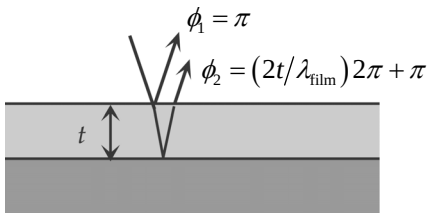
antennas is $d = \lambda/2$, the maximum path length difference is $\lambda/2$, which occurs along the line through the antennae, therefore the constructive interference only occurs at $\boxed{\theta_{\text{constructive}} = 90° \text{ and } 270°}$. As expected, these angles are reversed from those in phase, found in Example 34-5c.

60. If we consider the two rays shown in the diagram, we see that the first ray passes through with no reflection, while the second ray has reflected twice. If $n_{\text{film}} < n_{\text{glass}}$, the first reflection from the glass produces a phase shift equivalent to $\frac{1}{2}\lambda_{\text{film}}$, while the second reflection from the air produces no shift. When we compare the two rays at the film-glass surface, we see that the second ray has a total shift in phase, due to its longer path length ($2t$) and reflection $\left(\frac{1}{2}\lambda_{\text{film}}\right)$. We set this path difference equal to an integer number of wavelengths for maximum intensity and equal to a half-integer number of wavelengths for minimum intensity.

max: $2t + \frac{1}{2}\lambda_{\text{film}} = m\lambda_{\text{film}},\ m = 1, 2, 3, \ldots \ \rightarrow\ \boxed{t = \frac{\frac{1}{2}\left(m - \frac{1}{2}\right)\lambda}{n_{\text{film}}},\ m = 1, 2, 3, \ldots}$

min: $2t + \frac{1}{2}\lambda_{\text{film}} = \left(m + \frac{1}{2}\right)\lambda_{\text{film}},\ m = 0, 1, 2, 3, \ldots \ \rightarrow\ \boxed{t = \frac{\frac{1}{2}m\lambda}{n_{\text{film}}},\ m = 0, 1, 2, 3, \ldots}$

At $t = 0$, or in the limit $t \ll \lambda/n_{\text{film}}$, the transmitted beam will be at a minimum. Each time the thickness increases by a quarter wavelength the intensity switches between a maximum and a minimum.



If $n_{\text{film}} > n_{\text{glass}}$, the first reflection from the glass produces no shift, while the second reflection from the air also produces no shift. When we compare the two rays at the film-glass surface, we see that the second ray has a total shift due solely to the difference in path lengths, $2t$.
For maxima, we have

max: $2t = m\lambda_{\text{film}},\ m = 0, 1, 2, 3, \ldots \ \rightarrow\ \boxed{t = \frac{\frac{1}{2}m\lambda}{n_{\text{film}}},\ m = 0, 1, 2, 3, \ldots}$

min: $2t = \left(m - \frac{1}{2}\right)\lambda_{\text{film}},\ m = 1, 2, 3, \ldots \ \rightarrow\ \boxed{t = \frac{\frac{1}{2}\left(m - \frac{1}{2}\right)\lambda}{n_{\text{film}}},\ m = 1, 2, 3, \ldots}$

At $t = 0$, or in the limit $t \ll \lambda/n_{\text{film}}$, the transmitted beam will be at a maximum. Each time the thickness increases by a quarter wavelength the intensity switches between a maximum and a minimum.

61. With respect to the incident wave, the wave that reflects from the top surface of the film has a phase change of $\phi_1 = \pi$. With respect to the incident wave, the wave that reflects from the glass $(n = 1.52)$ at the bottom surface of the film has a phase change due to both the additional path length and reflection, so $\phi_2 = \left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi + \pi$. For constructive interference, the net phase change must be an even non-zero integer multiple of π.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\phi_{\text{net}} = \phi_2 - \phi_1 = \left[\left(\frac{2t}{\lambda_{\text{film}}}\right)2\pi + \pi\right] - \pi = m2\pi \quad \rightarrow \quad t = \tfrac{1}{2}m\lambda_{\text{film}} = \tfrac{1}{2}m\frac{\lambda}{n_{\text{film}}},\ m = 1,\ 2,\ 3,\ \ldots\ .$$

The minimum non-zero thickness occurs for $m = 1$.

$$t_{\min} = \frac{\lambda}{2n_{\text{film}}} = \frac{643\,\text{nm}}{2(1.34)} = \boxed{240\,\text{nm}}$$

62. The path difference to a point on the *x* axis from the two sources is $\Delta d = d_2 - d_1 = \sqrt{x^2 + d^2} - x$. For the two signals to be out of phase, this path difference must be an odd number of half-wavelengths, so $\Delta d = \left(m + \tfrac{1}{2}\right)\lambda,\ m = 0,\ 1,\ 2,\ \cdots$. Also, the maximum path difference is $d = 3\lambda$. Thus the path difference must be $\tfrac{1}{2}\lambda$, $\tfrac{3}{2}\lambda$, or $\tfrac{5}{2}\lambda$ for the signals to be out of phase (*m* = 0, 1, or 2). We solve for *x* for the three path differences.

$$\Delta d = \sqrt{x^2 + d^2} - x = \left(m + \tfrac{1}{2}\right)\lambda \quad \rightarrow \quad \sqrt{x^2 + d^2} = x + \left(m + \tfrac{1}{2}\right)\lambda \quad \rightarrow$$

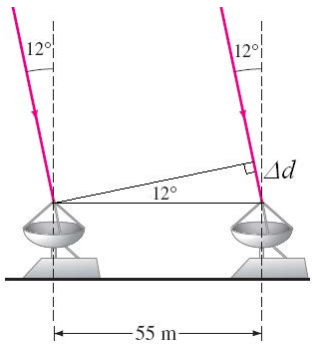
$$x^2 + d^2 = x^2 + 2x\left(m + \tfrac{1}{2}\right)\lambda + \left(m + \tfrac{1}{2}\right)^2\lambda^2 \quad \rightarrow$$

$$x = \frac{d^2 - \left(m + \tfrac{1}{2}\right)^2\lambda^2}{2\left(m + \tfrac{1}{2}\right)\lambda} = \frac{9\lambda^2 - \left(m + \tfrac{1}{2}\right)^2\lambda^2}{2\left(m + \tfrac{1}{2}\right)\lambda} = \frac{9 - \left(m + \tfrac{1}{2}\right)^2}{2\left(m + \tfrac{1}{2}\right)}\lambda$$

$$m = 0: x = \frac{9 - \left(0 + \tfrac{1}{2}\right)^2}{2\left(0 + \tfrac{1}{2}\right)}\lambda = \boxed{8.75\lambda} \ ; \ m = 1: x = \frac{9 - \left(1 + \tfrac{1}{2}\right)^2}{2\left(1 + \tfrac{1}{2}\right)}\lambda = \boxed{2.25\lambda}$$

$$m = 2: x = \frac{9 - \left(2 + \tfrac{1}{2}\right)^2}{2\left(2 + \tfrac{1}{2}\right)}\lambda = \boxed{0.55\lambda}$$

63. For both configurations, we have $d\sin\theta = m\lambda$. The angles and the orders are to be the same. The slit separations and wavelengths will be different. Use the fact that frequency and wavelength are related by $v = f\lambda$. The speed of sound in room-temperature air is given in Chapter 16 as 343 m/s.



$$d\sin\theta = m\lambda \quad \rightarrow \quad \frac{\sin\theta}{m} = \frac{\lambda}{d} = \frac{\lambda_{\text{L}}}{d_{\text{L}}} = \frac{\lambda_{\text{S}}}{d_{\text{S}}} \quad \rightarrow$$

$$d_{\text{S}} = d_{\text{L}}\frac{\lambda_{\text{S}}}{\lambda_{\text{L}}} = d_{\text{L}}\frac{\frac{v_{\text{S}}}{f_{\text{S}}}}{\frac{v_{\text{L}}}{f_{\text{L}}}} = d_{\text{L}}\frac{v_{\text{S}}f_{\text{L}}}{v_{\text{L}}f_{\text{S}}} = \left(1.0\times10^{-4}\,\text{m}\right)\left(\frac{343\,\text{m/s}}{3.00\times10^{8}\,\text{m/s}}\right)\left(\frac{4.6\times10^{14}\,\text{Hz}}{262\,\text{Hz}}\right) = \boxed{200\,\text{m}}$$

The answer has 2 significant figures.

64. Light traveling from a region 12° from the vertical would have to travel a slightly longer distance to reach the far antenna. Using trigonometry we calculate this distance, as was done in Young's double slit experiment. Dividing this additional distance by the speed of light gives us the necessary time shift.

$$\Delta t = \frac{\Delta d}{c} = \frac{\ell\sin\theta}{c} = \frac{(55\,\text{m})\sin12°}{3.00\times10^{8}\ \text{m/s}} = 3.81\times10^{-8}\ \text{s} = \boxed{38.1\,\text{ns}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

65. In order for the two reflected halves of the beam to be 180° out of phase with each other, the minimum path difference ($2t$) should be $\frac{1}{2}\lambda$ in the plastic. Notice that there is no net phase difference between the two halves of the beam due to reflection, because both halves reflect from the same material.

$$2t = \tfrac{1}{2}\frac{\lambda}{n} \quad \rightarrow \quad t = \frac{\lambda}{4n} = \frac{780\,\text{nm}}{4(1.55)} = \boxed{126\,\text{nm}}$$

66. We determine n for each angle using a spreadsheet. The results are shown below.

N	25	50	75	100	125	150
$\theta(\text{degree})$	5.5	6.9	8.6	10.0	11.3	12.5
n	1.75	2.19	2.10	2.07	2.02	1.98

The average value is $n_{\text{avg}} = \boxed{2.02}$. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH34.XLS," on tab "Problem 34.66."

CHAPTER 35: Diffraction and Polarization

Responses to Questions

1. Radio waves have a much longer wavelength than visible light and will diffract around normal-sized objects (like hills). The wavelengths of visible light are very small and will not diffract around normal-sized objects.

2. You see a pattern of dark and bright lines parallel to your fingertips in the narrow opening between your fingers.

3. Light from all points of an extended source produces diffraction patterns, and these many different diffraction patterns overlap and wash out each other so that no distinct pattern can be easily seen. When using white light, the diffraction patterns of the different wavelengths will overlap because the locations of the fringes depend on wavelength. Monochromatic light will produce a more distinct diffraction pattern.

4. (*a*) If the slit width is increased, the diffraction pattern will become more compact.
   (*b*) If the wavelength of the light is increased, the diffraction pattern will spread out.

5. (*a*) A slit width of 50 nm would produce a central maximum so spread out that it would cover the entire width of the screen. No minimum (and therefore no diffraction pattern) will be seen. The different wavelengths will all overlap, so the light on the screen will be white. It will also be dim, compared to the source, because it is spread out.
   (*b*) For the 50,000 nm slit, the central maximum will be very narrow, about a degree in width for the blue end of the spectrum and about a degree and a half for the red. The diffraction pattern will not be distinct, because most of the intensity will be in the small central maximum and the fringes for the different wavelengths of white light will not coincide.

6. (*a*) If the apparatus is immersed in water, the wavelength of the light will decrease $\left(\lambda' = \frac{\lambda}{n} \right)$ and the diffraction pattern will become more compact.
   (*b*) If the apparatus is placed in a vacuum, the wavelength of the light will increase slightly, and the diffraction pattern will spread out very slightly.

7. The intensity pattern is actually a function of the form $\left(\frac{\sin x}{x} \right)^2$ (see equations 35-7 and 35-8). The maxima of this function do not coincide exactly with the maxima of $\sin^2 x$. You can think of the intensity pattern as the combination of a $\sin^2 x$ function and a $1/x^2$ function, which forces the intensity function to zero and shifts the maxima slightly.

8. Similarities: Both have a regular pattern of light and dark fringes. The angular separation of the fringes is proportional to the wavelength of the light, and inversely proportional to the slit size or slit separation. Differences: The single slit diffraction maxima decrease in brightness from the center. Maxima for the double slit interference pattern would be equally bright (ignoring single slit effects) and are equally spaced.

9. No. *D* represents the slit width and *d* the distance between the centers of the slits. It is possible for the distance between the slit centers to be greater than the width of the slits; it is not possible for the distance between the slit centers to be less than the width of the slits.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

10. (*a*) Increasing the wavelength, λ, will spread out the diffraction pattern, since the locations of the minima are given by $\sin\theta = m\lambda/D$. The interference pattern will also spread out; the interference maxima are given by $\sin\theta = m\lambda/d$. The number of interference fringes in the central diffraction maximum will not change.
    (*b*) Increasing the slit separation, *d*, will decrease the spacing between the interference fringes without changing the diffraction, so more interference maxima will fit in the central maximum of the diffraction envelope.
    (*c*) Increasing the slit width, *D*, will decrease the angular width of the diffraction central maximum without changing the interference fringes, so fewer bright fringes will fit in the central maximum.

11. Yes. As stated in Section 35-5, "It is not possible to resolve detail of objects smaller than the wavelength of the radiation being used."

12. Yes. Diffraction effects will occur for both real and virtual images.

13. A large mirror has better resolution and gathers more light than a small mirror.

14. No. The resolving power of a lens is on the order of the wavelength of the light being used, so it is not possible to resolve details smaller than the wavelength of the light. Atoms have diameters of about 10^{-8} cm and the wavelength of visible light is on the order of 10^{-5} cm.

15. Violet light would give the best resolution in a microscope, because the wavelengths are shortest.

16. Yes. (See the introduction to Section 35-7.) The analysis for a diffraction grating of many slits is essentially the same as for Young's double slit interference. However, the bright maxima of a multiple-slit grating are much sharper and narrower than those in a double-slit pattern.

17. The answer depends on the slit spacing of the grating being used. If the spacing is small enough, only the first order will appear so there will not be any overlap. For wider slit spacing there can be overlap. If there is overlap, it will be the higher orders of the shorter wavelength light overlapping with lower orders of the longer wavelength light. See, for instance, Example 35-9, which shows the overlap of the third order blue light with the second order red light.

18. The bright lines will coincide, but those for the grating will be much narrower with wider dark spaces in between. The grating will produce a much sharper pattern.

19. (*a*) Violet light will be at the top of the rainbow created by the diffraction grating. Principal maxima for a diffraction grating are at positions given by $\sin\theta = \dfrac{m\lambda}{d}$. Violet light has a shorter wavelength than red light and so will appear at a smaller angle away from the direction of the horizontal incident beam.
    (*b*) Red light will appear at the top of the rainbow created by the prism. The index of refraction for violet light in a given medium is slightly greater than for red light in the same medium, and so the violet light will bend more and will appear farther from the direction of the horizontal incident beam.

20. The tiny peaks are produced when light from some but not all of the slits interferes constructively. The peaks are tiny because light from only some of the slits interferes constructively.

21. Polarization demonstrates the transverse wave nature of light, and cannot be explained if light is considered only as particles.

22. Take the sunglasses outside and look up at the sky through them. Rotate the sunglasses (about an axis perpendicular to the lens) through at least 180°. If the sky seems to lighten and darken as you rotate the sunglasses, then they are polarizing. You could also look at a liquid crystal display or reflections from the floor while rotating the glasses, or put one pair of glasses on top of the other and rotate them. If what you see through the glasses changes as you rotate them, then the glasses are polarizing.

23. Black. If there were no atmosphere, there would be no scattering of the sunlight coming to Earth.

Solutions to Problems

1. We use Eq. 35-1 to calculate the angular distance from the middle of the central peak to the first minimum. The width of the central peak is twice this angular distance.

$$\sin\theta_1 = \frac{\lambda}{D} \rightarrow \theta_1 = \sin^{-1}\left(\frac{\lambda}{D}\right) = \sin^{-1}\left(\frac{680\times10^{-9}\,\text{m}}{0.0365\times10^{-3}\,\text{m}}\right) = 1.067°$$

$$\Delta\theta = 2\theta_1 = 2(1.067°) = \boxed{2.13°}$$

2. The angle from the central maximum to the first dark fringe is equal to half the width of the central maximum. Using this angle and Eq. 35-1, we calculate the wavelength used.

$$\theta_1 = \tfrac{1}{2}\Delta\theta = \tfrac{1}{2}(32°) = 16°$$

$$\sin\theta_1 = \frac{\lambda}{D} \rightarrow \lambda = D\sin\theta_1 = \left(2.60\times10^{-3}\ \text{mm}\right)\ \sin(16°) = 7.17\times10^{-4}\ \text{mm} = \boxed{717\ \text{nm}}$$

3. The angle to the first maximum is about halfway between the angles to the first and second minima. We use Eq. 35-2 to calculate the angular distance to the first and second minima. Then we average these to values to determine the approximate location of the first maximum. Finally, using trigonometry, we set the linear distance equal to the distance to the screen multiplied by the tangent of the angle.

$$D\sin\theta_m = m\lambda \rightarrow \theta_m = \sin^{-1}\left(\frac{m\lambda}{D}\right)$$

$$\theta_1 = \sin^{-1}\left(\frac{1\times580\times10^{-9}\ \text{m}}{3.8\times10^{-6}\ \text{m}}\right) = 8.678° \qquad \theta_2 = \sin^{-1}\left(\frac{2\times580\times10^{-9}\ \text{m}}{3.8\times10^{-6}\ \text{m}}\right) = 17.774°$$

$$\theta = \frac{\theta_1+\theta_2}{2} = \frac{8.678°+17.774°}{2} = 13.23°$$

$$y = \ell\tan\theta_1 = (10.0\ \text{m})\tan(13.23°) = \boxed{2.35\ \text{m}}$$

4. (*a*) We use Eq. 35-2, using m=1,2,3,… to calculate the possible diffraction minima, when the wavelength is 0.50 cm.

$$D\sin\theta_m = m\lambda \rightarrow \theta_m = \sin^{-1}\left(\frac{m\lambda}{D}\right)$$

$$\theta_1 = \sin^{-1}\left(\frac{1\times0.50\ \text{cm}}{1.6\ \text{cm}}\right) = 18.2° \qquad \theta_2 = \sin^{-1}\left(\frac{2\times0.50\ \text{cm}}{1.6\ \text{cm}}\right) = 38.7°$$

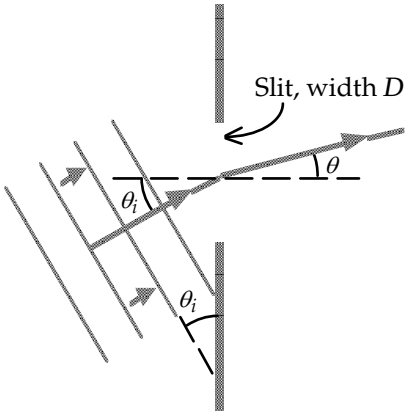
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\theta_3 = \sin^{-1}\left(\frac{3\times 0.50\text{ cm}}{1.6\text{ cm}}\right) = 69.6° \qquad \theta_4 = \sin^{-1}\left(\frac{4\times 0.50\text{ cm}}{1.6\text{ cm}}\right) \rightarrow \text{ no solution}$$

There are three diffraction minima: 18°, 39°, and 70°.

(*b*) We repeat the process from part (*a*) using a wavelength of 1.0 cm.

$$\theta_1 = \sin^{-1}\left(\frac{1\times 1.0\text{ cm}}{1.6\text{ cm}}\right) = 38.7° \qquad \theta_2 = \sin^{-1}\left(\frac{2\times 1.0\text{ cm}}{1.6\text{ cm}}\right) = \text{no real solution}$$



The only diffraction minima is at 39°

(*c*) We repeat the process from part (*a*) using a wavelength of 3.0 cm.

$$\theta_1 = \sin^{-1}\left(\frac{1\times 3.0\text{ cm}}{1.6\text{ cm}}\right) = \text{no real solution}$$

There are no diffraction minima.

5. The path-length difference between the top and bottom of the slit for the incident wave is $D\sin\theta_i$. The path-length difference between the top and bottom of the slit for the diffracted wave is $D\sin\theta$. When the net path-length difference is equal to a multiple of the wavelength, there will be an even number of segments of the wave having a path-length difference of $\lambda/2$. We set the path-length difference equal to m (an integer) times the wavelength and solve for the angle of the diffraction minimum.

$$D\sin\theta_i - D\sin\theta = m\lambda \rightarrow$$

$$\boxed{\sin\theta = \sin\theta_i - \frac{m\lambda}{D}, \quad m = \pm 1, \pm 2, ...}$$

From this equation we see that when $\theta = 23.0°$, the minima will be symmetrically distributed around a central maximum at 23.0°

6. The angle from the central maximum to the first bright maximum is half the angle between the first bright maxima on either side of the central maximum. The angle to the first maximum is about halfway between the angles to the first and second minima. We use Eq. 35-2, setting $m = 3/2$, to calculate the slit width, *D*.

$$\theta_1 = \tfrac{1}{2}\Delta\theta = \tfrac{1}{2}(35°) = 17.5°$$

$$D\sin\theta_m = m\lambda \rightarrow D = \frac{m\lambda}{\sin\theta_1} = \frac{(3/2)(633\text{ nm})}{\sin 17.5°} = 3157.6\text{ nm} \approx \boxed{3.2\,\mu\text{m}}$$

7. We use the distance to the screen and half the width of the diffraction maximum to calculate the angular distance to the first minimum. Then using this angle and Eq. 35-1 we calculate the slit width. Then using the slit width and the new wavelength we calculate the angle to the first minimum and the width of the diffraction maximum.

$$\tan\theta_1 = \frac{\left(\frac{1}{2}\Delta y_1\right)}{\ell} \rightarrow \theta_1 = \tan^{-1}\frac{\left(\frac{1}{2}\Delta y_1\right)}{\ell} = \tan^{-1}\frac{\left(\frac{1}{2}\times 0.06\text{ m}\right)}{2.20\text{ m}} = 0.781°$$

$$\sin\theta_1 = \frac{\lambda_1}{D} \rightarrow D = \frac{\lambda_1}{\sin\theta_1} = \frac{580\text{ nm}}{\sin 0.781°} = 42{,}537\text{ nm}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\sin\theta_2 = \frac{\lambda_2}{D} \rightarrow \theta_2 = \sin^{-1}\left(\frac{\lambda_2}{D}\right) = \sin^{-1}\left(\frac{460\,\text{nm}}{42{,}537\,\text{nm}}\right) = 0.620°$$

$$\Delta y_2 = 2\ell\tan\theta_2 = 2(2.20\,\text{m})\tan(0.620°) = 0.0476\,\text{m} \approx \boxed{4.8\,\text{cm}}$$

8. (*a*) There will be no diffraction minima if the angle for the first minimum is greater than 90°. We set the angle in Eq. 35-1 equal to 90° and solve for the slit width.

$$\sin\theta = \frac{\lambda}{D} \rightarrow D = \frac{\lambda}{\sin 90°} = \boxed{\lambda}$$

(*b*) For no visible light to exhibit a diffraction minimum, the slit width must be equal to the shortest visible wavelength.

$$D = \lambda_{\text{min}} = \boxed{400\text{ nm}}.$$

9. We set the angle to the first minimum equal to half of the separation angle between the dark bands. We insert this angle into Eq. 35-1 to solve for the slit width.

$$\theta = \tfrac{1}{2}\Delta\theta = \tfrac{1}{2}(55.0°) = 27.5°$$

$$\sin\theta = \frac{\lambda}{D} \rightarrow D = \frac{\lambda}{\sin\theta} = \frac{440\,\text{nm}}{\sin 27.5°} = \boxed{953\,\text{nm}}$$

10. We find the angle to the first minimum using Eq. 35-1. The distance on the screen from the central maximum is found using the distance to the screen and the tangent of the angle. The width of the central maximum is twice the distance from the central maximum to the first minimum.

$$\sin\theta_1 = \frac{\lambda}{D} \rightarrow \theta_1 = \sin^{-1}\left(\frac{\lambda}{D}\right) = \sin^{-1}\left(\frac{450\times10^{-9}\,\text{m}}{1.0\times10^{-3}\,\text{m}}\right) = \underline{\underline{0.02578°}}$$

$$y_1 = \ell\tan\theta_1 = (5.0\text{ m})\tan 0.02578° = 0.00225\text{ m}$$

$$\Delta y = 2y_1 = 2(0.00225\text{ m}) = 0.0045\text{ m} = \boxed{0.45\text{ cm}}$$

11. (*a*) For vertical diffraction we use the height of the slit (1.5 μm) as the slit width in Eq. 35-1 to calculate the angle between the central maximum to the first minimum. The angular separation of the first minima is equal to twice this angle.

$$\sin\theta_1 = \frac{\lambda}{D} \rightarrow \theta_1 = \sin^{-1}\frac{\lambda}{D} = \sin^{-1}\frac{780\times10^{-9}\,\text{m}}{1.5\times10^{-6}\,\text{m}} = 31.3°$$

$$\Delta\theta = 2\theta_1 = 2(31.3°) \approx \boxed{63°}$$

(*b*) To find the horizontal diffraction we use the width of the slit (3.0 μm) in Eq. 35-1.

$$\sin\theta_1 = \frac{\lambda}{D} \rightarrow \theta_1 = \sin^{-1}\frac{\lambda}{D} = \sin^{-1}\frac{780\times10^{-9}\,\text{m}}{3.0\times10^{-6}\,\text{m}} = 15.07°$$

$$\Delta\theta = 2\theta_1 = 2(15.07°) \approx \boxed{30°}$$

12. (*a*) If we consider the slit made up of *N* wavelets each of amplitude E_0, the total amplitude at the central maximum, where they are all in phase, is NE_0. Doubling the size of the slit doubles the number of wavelets and thus the total amplitude of the electric field. Because the intensity is proportional to the square of the electric field amplitude, the intensity at the central maximum is increased by a factor of 4.

$$I \propto E^2 = (2E_0)^2 = 4E_0^2 \propto \boxed{4I_0}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) From Eq. 35-1 we see that, for small angles, the width of the central maximum is inversely proportional to the slit width. Therefore doubling the slit width will cut the area of the central peak in half. Since the intensity is spread over only half the area, where the intensity is four times the initial intensity, the average intensity (or energy) over the central maximum has doubled. This is true for all fringes, so when the slit width is doubled, allowing twice the energy to pass through the slit, the average energy within each slit will also double, in accord with the conservation of energy.

13. We use Eq. 35-8 to calculate the intensity, where the angle θ is found from the displacement from the central maximum (15 cm) and the distance to the screen.

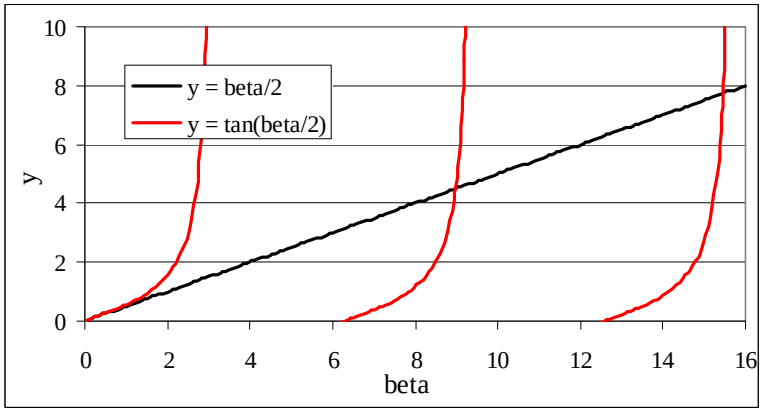
$$\tan\theta = \frac{y}{\ell} \rightarrow \theta = \tan^{-1}\left(\frac{15\,\text{cm}}{25\,\text{cm}}\right) = 31.0°$$

$$\beta = \frac{2\pi}{\lambda} D\sin\theta = \frac{2\pi}{\left(750\times10^{-9}\,\text{m}\right)}\left(1.0\times10^{-6}\,\text{m}\right)\sin 31.0° = 4.31\,\text{rad}$$

$$\frac{I}{I_0} = \left(\frac{\sin\beta/2}{\beta/2}\right)^2 = \left(\frac{\sin(4.31\,\text{rad}/2)}{4.31\,\text{rad}/2}\right)^2 = 0.1498 \approx \boxed{0.15}$$

So the light intensity at 15 cm is about 15% of the maximum intensity.

14. (*a*) The secondary maxima do not occur precisely where $\sin(\beta/2)$ is a maximum, that is at $\beta/2 = (m+\frac{1}{2})\pi$ where $m = 1, 2, 3, ...,$ because the diffraction intensity (Eq. 35-7) is the ratio of the sine function and $\beta/2$. Near the maximum of the sine function, the denominator of the intensity function causes the intensity to decrease more rapidly than the sine function causes it to increase. This results in the intensity reaching a maximum slightly before the sine function reaches its maximum.



(*b*) We set the derivative of Eq. 35-7 with respect to β equal to zero to determine the intensity extrema.

$$0 = \frac{dI}{d\beta} = \frac{d}{d\beta} I_o\left[\frac{\sin(\beta/2)}{\beta/2}\right]^2 = 2I_o\left[\frac{\sin(\beta/2)}{\beta/2}\right]\left[\frac{\cos(\beta/2)}{\beta} - \frac{\sin(\beta/2)}{\beta^2/2}\right]$$

When the first term in brackets is zero, the intensity is a minimum, so the intensity is a maximum when the second term in brackets is zero.

$$0 = \frac{\cos(\beta/2)}{\beta} - \frac{\sin(\beta/2)}{\beta^2/2} \rightarrow \boxed{\beta/2 = \tan(\beta/2)}$$

(*c*) The first and secondary maxima are found where these two curves intersect, or $\boxed{\beta_1 = 8.987}$ and $\boxed{\beta_2 = 15.451.}$ We calculate the percent difference between these and the maxima of the sine curve, $\beta_1' = 3\pi$ and $\beta_2' = 5\pi$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\left.\frac{\Delta\beta}{\beta}\right|_1 = \frac{\beta_1 - \beta_1'}{\beta_1'} = \frac{8.987 - 3\pi}{3\pi} = -0.0464 = \boxed{-4.64\%}$$

$$\left.\frac{\Delta\beta}{\beta}\right|_2 = \frac{15.451 - 5\pi}{5\pi} = -0.0164 = \boxed{-1.64\%}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH35.XLS," on tab "Problem 35.14."

15. If the central diffraction peak contains nine fringes, there will be four fringes on each side of the central peak. Thus the fifth maximum of the double slit must coincide with the first minimum of the diffraction pattern. We use Eq. 34-2a with $m = 5$ to find the angle of the fifth interference maximum and set that angle equal to the first diffraction minimum, given by Eq. 35-1, to solve for the ratio of the slit separation to slit width.

$$d\sin\theta = m\lambda \;\rightarrow\; \sin\theta = \frac{5\lambda}{d} \;;\; \sin\theta = \frac{\lambda}{D} = \frac{5\lambda}{d} \;\rightarrow\; \boxed{d = 5D}$$

16. (*a*) If the central diffraction peak is to contain seventeen fringes, there will be eight fringes on each side of the central peak. Thus, the ninth minimum of the double slit must coincide with the first minimum of the diffraction pattern. We use Eq. 34-2b with $m = 8$ to find the angle of the ninth interference minimum and set that angle equal to the first diffraction minimum, given by Eq. 35-1, to solve for the ratio of the slit separation to slit width.

$$d\sin\theta = \left(m + \tfrac{1}{2}\right)\lambda \;\rightarrow\; \sin\theta = \frac{\left(8 + \frac{1}{2}\right)\lambda}{d} = \frac{8.5\lambda}{d}$$

$$\sin\theta = \frac{\lambda}{D} = \frac{8.5\lambda}{d} \;\rightarrow\; \boxed{d = 8.5D}$$

Therefore, for the first diffraction minimum to be at the ninth interference minimum, the separation of slits should be 8.5 times the slit width.

(*b*) If the first diffraction minimum is to occur at the ninth interference maximum, we use Eq. 34-2a with $m = 9$ to find the angle of the ninth interference maximum and set that angle equal to the first diffraction minimum, given by Eq. 35-1, to solve for the ratio of the slit separation to slit width.

$$d\sin\theta = m\lambda \;\rightarrow\; \sin\theta = \frac{9\lambda}{d} = \frac{9\lambda}{d} \;;\; \sin\theta = \frac{\lambda}{D} = \frac{9\lambda}{d} \;\rightarrow\; \boxed{d = 9D}$$

Therefore, for the first diffraction minimum to be at the ninth interference maximum, the separation of slits should be 9 times the slit width.

17. Given light with $\lambda = 605\text{ nm}$ passing through double slits with separation $d = 0.120\text{ mm}$, we use Eq. 34-2a to find the highest integer m value for the interference fringe that occurs before the angle $\theta = 90^\circ$.

$$d\sin\theta = m\lambda \;\rightarrow\; m = \frac{\left(0.120\times10^{-3}\text{m}\right)\sin 90^\circ{}^\circ}{605\times10^{-9}\text{m}} = 198$$

So, including the $m = 0$ fringe, and the symmetric pattern of interference fringes on each side of $\theta = 0$, there are potentially a total of $198 + 198 + 1 = 397$ fringes. However, since slits have width $a = 0.040\text{ mm}$, the potential interference fringes that coincide with the slits' diffraction minima will be absent. Let the diffraction minima be indexed by $m' = 1, 2, 3,$ etc. We then set the diffraction angles in Eq. 34-2a and Eq. 35-2 equal to solve for the *m* values of the absent fringes.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\sin\theta = \frac{m'\lambda}{D} = \frac{m\lambda}{d} \quad \rightarrow \quad \frac{m}{m'} = \frac{d}{D} = \frac{0.120\text{ mm}}{0.040\text{ mm}} = 3 \quad \rightarrow \quad m = 3m'$$

Using $m' = 1, 2, 3,$ etc., the 66 interference fringes on each side of $\theta = 0$ with $m = 3, 6, 9, ..., 198$ will be absent. Thus the number of fringes on the screen is $397 - 2(66) = \boxed{265}$.

18. In a double-slit experiment, if the central diffraction peak contains 13 interference fringes, there is the $m = 0$ fringe, along with fringes up to $m = 6$ on each side of $\theta = 0$. Then, at angle θ, the $m = 7$ interference fringe coincides with the first diffraction minima. We set this angle in Eq. 34-2a and 35-2 equal to solve for the relationship between the slit width and separation.

$$\sin\theta_1 = \frac{m'\lambda}{D} = \frac{m\lambda}{d} \quad \rightarrow \quad \frac{d}{D} = \frac{m}{m'} = \frac{7}{1} = 7 \quad \rightarrow \quad d = 7D$$

Now, we use these equations again to find the *m* value at the second diffraction minimum, $m' = 0$.

$$\sin\theta_2 = \frac{m'\lambda}{D} = \frac{m\lambda}{d} \quad \rightarrow \quad m = m'\frac{d}{D} = 2\frac{7D}{D} = 14$$

Thus, the $\boxed{\text{six fringes}}$ corresponding to $m = 8$ to $m = 13$ will occur within the first and second diffraction minima.

19. (*a*) The angle to each of the maxima of the double slit are given by Eq. 34-2a. The distance of a fringe on the screen from the center of the pattern is equal to the distance between the slit and screen multiplied by the tangent of the angle. For small angles, we can set the tangent equal to the sine of the angle. The slit spacing is found by subtracting the distance between two adjacent fringes.

$$\sin\theta_m = \frac{m\lambda}{d} \qquad y_m = \ell\tan\theta_m \approx \ell\sin\theta_m = \ell\frac{m\lambda}{d}$$

$$\Delta y = y_{m+1} - y_m = \ell\frac{(m+1)\lambda}{d} - \ell\frac{m\lambda}{d} = \frac{\ell\lambda}{d} = \frac{(1.0\text{ m})(580\times10^{-9}\text{ m})}{0.030\times10^{-3}\text{m}} = 0.019\text{ m} = \boxed{1.9\text{ cm}}$$

(*b*) We use Eq. 35-1 to determine the angle between the center and the first minimum. Then by multiplying the distance to the screen by the tangent of the angle we find the distance from the center to the first minima. The distance between the two first order diffraction minima is twice the distance from the center to one of the minima.

$$\sin\theta_1 = \frac{\lambda}{D} \quad \rightarrow \quad \theta_1 = \sin^{-1}\frac{\lambda}{D} = \sin^{-1}\frac{580\times10^{-9}\text{ m}}{0.010\times10^{-3}\text{m}} = 3.325°$$

$$y_1 = \ell\tan\theta_1 = (1.0\text{ m})\tan 3.325° = 0.0581\text{ m}$$

$$\Delta y = 2y_1 = 2(0.0581\text{m}) = 0.116\text{ m} \approx \boxed{12\text{ cm}}$$

20. We set $d = D$ in Eqs. 34-4 and 35-6 to show $\beta = \delta$. Replacing δ with β in Eq. 35-9, and using the double angle formula we show that Eq. 35-9 reduces to Eq. 35-7, with $\beta' = 2\beta$. Finally using Eq. 35-6 again, we show that $\beta' = 2\beta$ implies that the new slit width D' is simply double the initial slit width.

$$\delta = \frac{2\pi}{\lambda}d\sin\theta = \frac{2\pi}{\lambda}D\sin\theta = \beta$$

$$I_\theta = I_0\left(\frac{\sin\beta/2}{\beta/2}\right)^2\cos^2(\delta/2) = I_0\frac{\sin^2(\beta/2)\cos^2(\beta/2)}{(\beta/2)^2} = I_0\frac{\frac{1}{4}\sin^2\left[2(\beta/2)\right]}{(\beta/2)^2}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= I_0 \frac{\sin^2\beta}{\beta^2} = \boxed{I_0 \frac{\sin^2(\beta'/2)}{(\beta'/2)^2}}, \text{ where } \beta' = 2\beta.$$

$$\beta' = \frac{2\pi}{\lambda} D' \sin\theta = 2\left(\frac{2\pi}{\lambda} D \sin\theta\right) \rightarrow \boxed{D' = 2D}$$

21. Using Eq. 34-2a we determine the angle at which the third-order interference maximum occurs. Then we use Eq. 35-9 to determine the ratio of the intensity of the third-order maximum, where β is given by Eq. 35-6 and δ is given by Eq. 34-4.

$$d\sin\theta = m\lambda \;\Rightarrow\; \theta = \sin^{-1}\left(\frac{m\lambda}{d}\right) = \sin^{-1}\left(\frac{3\lambda}{40.0\lambda}\right) = 4.301°$$

$$\frac{\beta}{2} = \frac{2\pi}{2\lambda} D\sin\theta = \frac{\pi(40.0\lambda/5)}{\lambda}\sin(4.301°) = 1.885 \text{ rad}$$

$$\frac{\delta}{2} = \frac{2\pi d}{2\lambda}\sin\theta = \frac{\pi(40.0\lambda)}{\lambda}\sin(4.301°) = 9.424 \text{ rad}$$

$$I = I_o\left[\frac{\sin(\beta/2)}{\beta/2}\right]^2\left[\cos\left(\frac{\delta}{2}\right)\right]^2 = I_o\left[\frac{\sin(1.885 \text{ rad})}{1.885 \text{ rad}}\right]^2\left[\cos(9.424)\right]^2 = \boxed{0.255 I_o}$$

22. We use Eq. 34-2a to determine the order of the double slit maximum that corresponds to the same angle as the first order single slit minimum, from Eq. 35-1. Since this double slit maximum is darkened, inside the central diffraction peak, there will be the zeroth order fringe and on either side of the central peak a number of maximum equal to one less than the double slit order. Therefore, there will be $2(m-1)+1$, or $2m-1$ fringes.

$$d\sin\theta = m\lambda \;\rightarrow\; m = \frac{d\sin\theta}{\lambda} = \frac{d}{\lambda}\left(\frac{\lambda}{D}\right) = \frac{d}{D} \;;\; N = 2m - 1 = 2\frac{d}{D} - 1$$

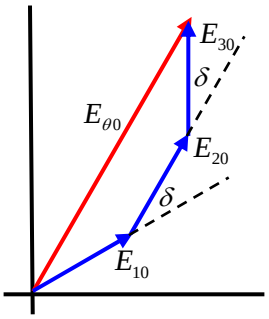
(*a*) We first set the slit separation equal to twice the slit width, $d = 2.00\,D$.

$$N = 2\frac{2.00D}{D} - 1 = \boxed{3}$$

(*b*) Next we set $d = 12.0\,D$.

$$N = 2\frac{12.00D}{D} - 1 = \boxed{23}$$

(*c*) For the previous two parts, the ratio of slits had been an integer value. This corresponded to the single slit minimum overlapping the double slit maximum. Now that $d = 4.50\,D$, the single slit minimum overlaps a double slit minimum. Therefore, the last order maximum, $m = 4$, is not darkened and $N = 2m + 1$.



$$N = 2m + 1 = 2(4) + 1 = \boxed{9}$$

(*d*) In this case the ratio of the slit separation to slit width is not an integer, nor a half-integer value. The first order single-slit minimum falls between the seventh order maximum and the seventh order minimum. Therefore, the seventh order maximum will partially be seen as a fringe.

$$N = 2m + 1 = 2(7) + 1 = \boxed{15}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

23. (*a*) If $D \approx \lambda$, the central maximum of the diffraction pattern will be very wide. Thus we need consider only the interference between slits. We construct a phasor diagram for the interference, with $\delta = \frac{2\pi}{\lambda} d \sin\theta$ as the phase difference between adjacent slits. The magnitude of the electric fields of the slits will have the same magnitude, $E_{10} = E_{20} = E_{30} = E_0$. From the symmetry of the phasor diagram we see that $\phi = \delta$. Adding the three electric field vectors yields the net electric field.

$$E_{\theta 0} = E_{10}\cos\delta + E_{20} + E_{30}\cos\delta = E_0\left(1 + 2\cos\delta\right)$$

The central peak intensity occurs when $\delta = 0$. We set the intensity proportional to the square of the electric field and calculate the ratio of the intensities.

$$\frac{I_\theta}{I_0} = \frac{E_{\theta 0}^2}{E_{00}^2} = \frac{E_0^2\left(1+2\cos\delta\right)^2}{E_0^2\left(1+2\cos 0\right)^2} = \boxed{\frac{\left(1+2\cos\delta\right)^2}{9}}$$

(*b*) We find the locations of the maxima and minima by setting the first derivative of the intensity equal to zero.

$$\frac{dI_\theta}{d\delta} = \frac{d}{d\delta}\frac{I_0}{9}\left(1+2\cos\delta\right)^2 = \frac{2I_0}{9}\left(1+2\cos\delta\right)\left(-2\sin\delta\right) = 0$$

This equation is satisfied when either of the terms in parentheses is equal to zero. When $1 + 2\cos\delta = 0$, the intensity equals zero and is a minimum.

$$1 + 2\cos\delta = 0 \rightarrow \delta = \cos^{-1}\left(-\tfrac{1}{2}\right) = \frac{2\pi}{3}, \frac{4\pi}{3}, \frac{8\pi}{3}, \frac{10\pi}{3}, \ldots$$

Maxima occur for $\sin\delta = 0$, which also says $\cos\delta = \pm 1$.

$$\sin\delta = 0 \rightarrow \delta = \sin^{-1} 0 = 0, \pi, 2\pi, 3\pi, \ldots$$

When $\cos\delta = 1$, the intensity is a principal maximum. When $\cos\delta = -1$, the intensity is a secondary maximum.

$$I_\theta(0) = I_0\frac{\left(1+2\cos\delta\right)^2}{9} = I_0\frac{\left(1+2\cos 0\right)^2}{9} = I_0$$

$$I_\theta(\pi) = I_0\frac{\left(1+2\cos\pi\right)^2}{9} = I_0\frac{\left(1+2(-1)\right)^2}{9} = \frac{I_0}{9}$$

$$I_\theta(2\pi) = I_0\frac{\left(1+2\cos 2\pi\right)^2}{9} = I_0\frac{\left(1+2\right)^2}{9} = I_0$$

Thus we see that, since $\cos\delta$ alternates between +1 and –1, there is only a single secondary maximum between each principal maximum.

24. The angular resolution is given by Eq. 35-10.

$$\theta = 1.22\frac{\lambda}{D} = 1.22\frac{560\times10^{-9}\ \text{m}}{254\times10^{-2}\ \text{m}} = 2.69\times10^{-7}\ \text{rad}\left(\frac{180^\circ}{\pi\ \text{rad}}\right)\left(\frac{3600''}{1^\circ}\right) = \boxed{0.055''}$$

25. The angular resolution is given by Eq. 35-10. The distance between the stars is the angular resolution times the distance to the stars from the Earth.

$$\theta = 1.22\frac{\lambda}{D}\ ;\ \ell = r\theta = 1.22\frac{r\lambda}{D} = 1.22\frac{(16\text{ly})\left(\frac{9.46\times10^{15}\text{m}}{1\text{ly}}\right)\left(550\times10^{-9}\text{m}\right)}{(0.66\,\text{m})} = \boxed{1.5\times10^{11}\text{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

26. We find the angle θ subtended by the planet by dividing the orbital radius by the distance of the star to the earth. Then using Eq. 35-10 we calculate the minimum diameter aperture needed to resolve this angle.

$$\theta = \frac{r}{d} = \frac{1.22\lambda}{D} \rightarrow$$

$$D = \frac{1.22\lambda d}{r} = \frac{1.22\left(550\times10^{-9}\,\text{m}\right)\left(4\,\text{ly}\right)\left(9.461\times10^{15}\,\text{m/ly}\right)}{\left(1\,\text{AU}\right)\left(1.496\times10^{11}\,\text{m/AU}\right)} = 0.17\,\text{m} \approx \boxed{20\,\text{cm}}$$

27. We find the angular half-width of the flashlight beam using Eq. 35-10 with $D = 5$ cm and $\lambda = 550$ nm. We set the diameter of the beam equal to twice the radius, where the radius of the beam is equal to the angular half-width multiplied by the distance traveled, 3.84×10^{8} m.

$$\theta = \frac{1.22\lambda}{D} = \frac{1.22\left(550\times10^{-9}\,\text{m}\right)}{0.050\,\text{m}} = 1.3\times10^{-5}\,\text{rad}$$

$$d = 2\left(r\theta\right) = 2\left(3.84\times10^{8}\,\text{m}\right)\left(1.3\times10^{-5}\,\text{rad}\right) = \boxed{1.0\times10^{4}\,\text{m}}$$

28. To find the focal length of the eyepiece we use Eq. 33-7, where the objective focal length is 2.00 m, θ' is the ratio of the minimum resolved distance and 25 cm, and θ is the ratio of the object on the moon and the distance to the moon. We ignore the inversion of the image.

$$\frac{f_o}{f_e} = \frac{\theta'}{\theta} \rightarrow f_e = f_o\frac{\theta}{\theta'} = f_o\frac{\left(d_o/\ell\right)}{\left(d/N\right)} = \left(2.0\,\text{m}\right)\frac{\left(7.5\,\text{km}/384{,}000\,\text{km}\right)}{\left(0.10\,\text{mm}/250\,\text{mm}\right)} = 0.098\,\text{m} = \boxed{9.8\,\text{cm}}$$

We use Eq. 35-10 to determine the resolution limit.

$$\theta = 1.22\frac{\lambda}{D} = 1.22\frac{560\times10^{-9}\ \text{m}}{0.11\,\text{m}} = \boxed{6.2\times10^{-6}\ \text{rad}}$$

This corresponds to a minimum resolution distance, $r = \left(384{,}000\,\text{km}\right)\left(6.2\times10^{-6}\,\text{rad}\right) = \boxed{2.4\,\text{km}}$, which is smaller than the 7.5 km object we wish to observe.

29. We set the resolving power as the focal length of the lens multiplied by the angular resolution, as in Eq. 35-11. The resolution is the inverse of the resolving power.

$$\frac{1}{RP(f/2)} = \left[\frac{1.22\lambda f}{D}\right]^{-1} = \frac{D}{1.22\lambda f} = \frac{25\ \text{mm}}{1.22\left(560\times10^{-6}\,\text{mm}\right)\left(50.0\ \text{mm}\right)} = \boxed{730\ \text{lines/mm}}$$

$$\frac{1}{RP(f/16)} = \frac{3.0\ \text{mm}}{1.22\left(560\times10^{-6}\,\text{mm}\right)\left(50.0\ \text{mm}\right)} = \boxed{88\ \text{lines/mm}}$$

30. We use Eq. 35-13 to calculate the angle for the second order maximum.

$$d\sin\theta = m\lambda \rightarrow \theta = \sin^{-1}\left(\frac{m\lambda}{d}\right) = \sin^{-1}\left(\frac{2\left(480\times10^{-9}\ \text{m}\right)}{1.35\times10^{-5}\ \text{m}}\right) = \boxed{4.1°}$$

31. We use Eq. 35-13 to calculate the wavelengths from the given angles. The slit separation, *d*, is the inverse of the number of lines per cm, *N*. We assume that 12,000 is good to 3 significant figures.

$$d\sin\theta = m\lambda \rightarrow \lambda = \frac{\sin\theta}{Nm}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\lambda_1 = \frac{\sin 28.8°}{12{,}000\ /\text{cm}} = 4.01\times10^{-5}\ \text{cm} = \boxed{401\ \text{nm}} \qquad \lambda_2 = \frac{\sin 36.7°}{12{,}000\ /\text{cm}} = 4.98\times10^{-5}\ \text{cm} = \boxed{498\ \text{nm}}$$

$$\lambda_3 = \frac{\sin 38.6°}{12{,}000\ /\text{cm}} = 5.201\times10^{-5}\ \text{cm} = \boxed{520\ \text{nm}} \qquad \lambda_4 = \frac{\sin 47.9°}{12{,}000\ /\text{cm}} = 6.18\times10^{-5}\ \text{cm} = \boxed{618\ \text{nm}}$$

32. We use Eq. 35-13 to find the wavelength, where the number of lines, *N*, is the inverse of the slit separation, or $d=1/N$.

$$d\sin\theta = m\lambda \rightarrow \lambda = \frac{\sin\theta}{mN} = \frac{\sin 26.0°}{3(3500\ /\text{cm})} = 4.17\times10^{-5}\text{cm} \approx \boxed{420\,\text{nm}}$$

33. Because the angle increases with wavelength, to have a complete order we use the largest wavelength. We set the maximum angle is 90° to determine the largest integer *m* in Eq. 35-13.

$$d\sin\theta = m\lambda \rightarrow m = \frac{\sin\theta}{\lambda N} = \frac{\sin 90°}{(700\times10^{-9}\ \text{m})(6800\ /\text{cm})(100\ \text{cm/m})} = 2.1$$

Thus, two full spectral orders can be seen on each side of the central maximum, and a portion of the third order.

34. We find the slit separation from Eq. 35-13. Then set the number of lines per centimeter equal to the inverse of the slit separation, $N=1/d$.

$$d\sin\theta = m\lambda \rightarrow N = \frac{1}{d} = \frac{\sin\theta}{m\lambda} = \frac{\sin 15.0°}{3(650\times10^{-7}\,\text{cm})} = \boxed{1300\,\text{lines/cm}}$$

35. Since the same diffraction grating is being used for both wavelengths of light, the slit separation will be the same. We solve Eq. 35-13 for the slit separation for both wavelengths and set the two equations equal. The resulting equation is then solved for the unknown wavelength.

$$d\sin\theta = m\lambda \;\Rightarrow\; d = \frac{m_1\lambda_1}{\sin\theta_1} = \frac{m_2\lambda_2}{\sin\theta_2} \;\Rightarrow\; \lambda_2 = \frac{m_1}{m_2}\frac{\sin\theta_2}{\sin\theta_1}\lambda_1 = \frac{2}{1}\frac{\sin 20.6°}{\sin 53.2°}(632.8\,\text{nm}) = \boxed{556\,\text{nm}}$$

36. We find the first order angles for the maximum and minimum wavelengths using Eq. 35-13, where the slit separation distance is the inverse of the number of lines per centimeter. Then we set the distance from the central maximum of the maximum and minimum wavelength equal to the distance to the screen multiplied by the tangent of the first order angle. The width of the spectrum is the difference in these distances.

$$d\sin\theta = m\lambda \rightarrow \theta = \sin^{-1}\left(\frac{m\lambda}{d}\right) = \sin^{-1}(m\lambda N)$$

$$\theta_1 = \sin^{-1}\left[(410\times10^{-7}\,\text{cm})(7800\ \text{lines/cm})\right] = 18.65°$$

$$\theta_2 = \sin^{-1}\left[(750\times10^{-7}\,\text{cm})(7800\ \text{lines/cm})\right] = 35.80°$$

$$\Delta y = y_2 - y_1 = \ell(\tan\theta_2 - \tan\theta_1) = (2.80\ \text{m})(\tan 35.80° - \tan 18.65°) = \boxed{1.1\,\text{m}}$$

37. We find the second order angles for the maximum and minimum wavelengths using Eq. 35-13, where the slit separation distance is the inverse of the number of lines per centimeter. Subtracting these two angles gives the angular width.

$$d\sin\theta = m\lambda \rightarrow \theta = \sin^{-1}\left(\frac{m\lambda}{d}\right) = \sin^{-1}(m\lambda N)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\theta_1 = \sin^{-1}\left[2\left(4.5\times10^{-7}\text{ m}\right)\left(6.0\times10^{5}\text{ /m}\right)\right] = 32.7°$$

$$\theta_2 = \sin^{-1}\left[2\left(7.0\times10^{-7}\text{ m}\right)\left(6.0\times10^{5}\text{ /m}\right)\right] = 57.1°$$

$$\Delta\theta = \theta_2 - \theta_1 = 57.1° - 32.7° = \boxed{24°}$$

38. The $m = 1$ brightness maximum for the wavelength of 1200 nm occurs at angle θ. At this same angle $m = 2$, $m = 3$, etc. brightness maximum will form for other wavelengths. To find these wavelengths, we use Eq. 35-13, where the right hand side of the equation remains constant, and solve for the wavelengths of higher order.

$$d\sin\theta = m_1\lambda_1 = m\lambda_m \Rightarrow \lambda_m = \frac{m_1\lambda_1}{m} = \frac{\lambda_1}{m}$$

$$\lambda_2 = \frac{1200\text{ nm}}{2} = 600\text{ nm} \qquad \lambda_3 = \frac{1200\text{ nm}}{3} = 400\text{ nm} \qquad \lambda_4 = \frac{1200\text{ nm}}{4} = 300\text{ nm}$$

Higher order maxima will have shorter wavelengths. Therefore in the range 360 nm to 2000 nm, the only wavelengths that have a maxima at the angle θ are $\boxed{\text{600 nm and 400 nm}}$ besides the 1200 nm.

39. Because the angle increases with wavelength, we compare the maximum angle for the second order with the minimum angle for the third order, using Eq. 35-13, by calculating the ratio of the sines for each angle. Since this ratio is greater than one, the maximum angle for the second order is larger than the minimum angle for the first order and the spectra overlap.

$$d\sin\theta = m\lambda \;\rightarrow\; \sin\theta = \left(\frac{m\lambda}{d}\right) \;;\; \frac{\sin\theta_2}{\sin\theta_3} = \frac{2\lambda_2/d}{3\lambda_3/d} = \frac{2\lambda_2}{3\lambda_3} = \frac{2\left(700\text{ nm}\right)}{3\left(400\text{ nm}\right)} = 1.2$$

To determine which wavelengths overlap, we set this ratio of sines equal to one and solve for the second order wavelength that overlaps with the shortest wavelength of the third order. We then repeat this process to find the wavelength of the third order that overlaps with the longest wavelength of the second order.

$$\frac{\sin\theta_2}{\sin\theta_3} = 1 = \frac{2\lambda_2/d}{3\lambda_3/d} = \frac{2\lambda_2}{3\lambda_3} \;\rightarrow\; \lambda_3 = \frac{2}{3}\lambda_{2,\max} = \frac{2}{3}\left(700\text{ nm}\right) = 467\text{ nm}$$

$$\rightarrow\; \lambda_2 = \frac{3}{2}\lambda_{3,\min} = \frac{3}{2}\left(400\text{ nm}\right) = 600\text{ nm}$$

Therefore, the wavelengths $\boxed{\text{600 nm – 700 nm of the second order}}$ overlap with the wavelengths $\boxed{\text{400 nm – 467 nm of the third order.}}$ Note that these wavelengths are independent of the slit spacing.

40. We set the diffraction angles as one half the difference between the angles on opposite sides of the center. Then we solve Eq. 35-13 for the wavelength, with *d* equal to the inverse of the number of lines per centimeter.

$$\theta_1 = \frac{\theta_r - \theta_\ell}{2} = \frac{26°38' - \left(-26°18'\right)}{2} = 26°28' = 26 + 28/60 = 26.47°$$

$$\lambda_1 = d\sin\theta = \frac{\sin\theta}{N} = \frac{\sin 26.47°}{9650\text{ line/cm}} = 4.618\times10^{-5}\text{ cm} = \boxed{462\text{ nm}}$$

$$\theta_2 = \frac{\theta_{2r} - \theta_{2\ell}}{2} = \frac{41°02' - \left(-40°27'\right)}{2} = 40°44.5' = 40 + 44.5/60 = 40.742°$$

$$\lambda_2 = \frac{\sin 40.742°}{9650\text{ line/cm}} = 6.763\times10^{-5}\text{ cm} = \boxed{676\text{ nm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41. If the spectrometer were immersed in water, the wavelengths calculated in Problem 40 would be wavelengths in water. To change those wavelengths into wavelengths in air, we must multiply by the index of refraction.

$$\lambda_{\underset{\text{air}}{1}} = \left(4.618\times10^{-5}\text{cm}\right)(1.33) = \boxed{614\,\text{nm}} \;;\; \lambda_{\underset{\text{air}}{2}} = \left(6.763\times10^{-5}\text{cm}\right)(1.33) = \boxed{899\,\text{nm}}$$

Note that the second wavelength is not in the visible range.

42. We solve Eq. 35-13 for the slit separation width, *d*, using the given information. Then setting *m*=3, we solve for the angle of the third order maximum.

$$\sin\theta = \frac{m\lambda}{d} \;\rightarrow\; d = \frac{m\lambda}{\sin\theta} = \frac{1(589\,\text{nm})}{\sin 16.5^\circ} = 2074\,\text{nm} = \boxed{2.07\,\mu\text{m}}$$

$$\theta_3 = \sin^{-1}\left(\frac{m\lambda}{d}\right) = \sin^{-1}\left(\frac{3\times589\,\text{nm}}{2074\,\text{nm}}\right) = \boxed{58.4^\circ}$$

43. We find the angle for each "boundary" color from Eq. 35-13, and then use the fact that the displacement on the screen is given by $\tan\theta = \frac{y}{L}$, where *y* is the displacement on the screen from the central maximum, and *L* is the distance from the grating to the screen.

$$\sin\theta = \frac{m\lambda}{d} \;;\; d = \frac{1}{610\,\text{lines/mm}}\left(\frac{1\text{m}}{10^3\text{mm}}\right) = \left(1/6.1\times10^5\right)\text{m} \;;\; y = L\tan\theta = L\tan\left[\sin^{-1}\frac{m\lambda}{d}\right]$$

$$\ell_1 = L\tan\left[\sin^{-1}\frac{m\lambda_{\text{red}}}{d}\right] - L\tan\left[\sin^{-1}\frac{m\lambda_{\text{violet}}}{d}\right]$$

$$= (0.32\,\text{m})\left\{\tan\left[\sin^{-1}\frac{(1)\left(700\times10^{-9}\text{m}\right)}{\left(1/6.1\times10^5\right)\text{m}}\right] - \tan\left[\sin^{-1}\frac{(1)\left(400\times10^{-9}\text{m}\right)}{\left(1/6.1\times10^5\right)\text{m}}\right]\right\}$$

$$= 0.0706\,\text{m} \approx \boxed{7\,\text{cm}}$$

$$\ell_2 = L\tan\left[\sin^{-1}\frac{m\lambda_{\text{red}}}{d}\right] - L\tan\left[\sin^{-1}\frac{m\lambda_{\text{violet}}}{d}\right]$$

$$= (0.32\,\text{m})\left\{\tan\left[\sin^{-1}\frac{(2)\left(700\times10^{-9}\text{m}\right)}{\left(1/6.1\times10^5\right)\text{m}}\right] - \tan\left[\sin^{-1}\frac{(2)\left(400\times10^{-9}\text{m}\right)}{\left(1/6.1\times10^5\right)\text{m}}\right]\right\}$$

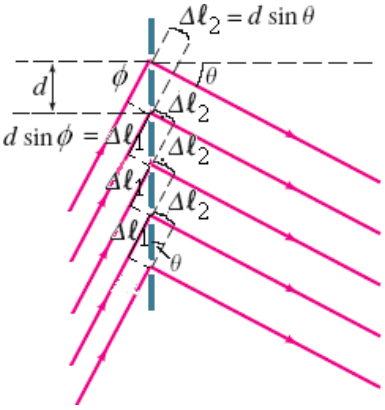
$$= 0.3464\,\text{m} \approx \boxed{35\,\text{cm}}$$

The second order rainbow is dispersed over a larger distance.

44. (*a*) Missing orders occur when the angle to the interference maxima (Eq. 34-2a) is equal to the angle of a diffraction minimum (Eq. 35-2). We set $d = 2D$ and show that the even interference orders are missing.

$$\sin\theta = \frac{m_1\lambda}{d} = \frac{m_2\lambda}{D} \;\rightarrow\; \frac{m_1}{m_2} = \frac{d}{D} = \frac{2D}{D} = 2 \;\rightarrow\; m_1 = 2m_2$$

Since $m_2 = 1, 2, 3, 4, \ldots$, all even orders of m_1 correspond to the diffraction minima and will be missing from the interference pattern.



(*b*) Setting the angle of interference maxima equal to the angle of diffraction minimum, with the orders equal to integers we determine the relationship between the slit size and separation that will produce missing orders.

$$\sin\theta = \frac{m_1\lambda}{d} = \frac{m_2\lambda}{D} \quad \rightarrow \quad \boxed{\frac{d}{D} = \frac{m_1}{m_2}}$$

(*c*) When $d = D$, all interference maxima will overlap with diffraction minima so that no fringes will exist. This is expected because if the slit width and separation distance are the same, the slits will merge into one single opening.

45. (*a*) Diffraction maxima occur at angles for which the incident light constructive interferes. That is, when the path length difference between two rays is equal to an integer number of wavelengths. Since the light is incident at an angle ϕ relative to the grating, each succeeding higher ray, as shown in the diagram, travels a distance $\Delta\ell_1 = d\sin\phi$ farther to reach the grating. After passing through the grating the higher rays travel a distance to the screen that is again longer by $\Delta\ell_2 = d\sin\theta$. By setting the total path length difference equal to an integer number of wavelengths, we are able to determine the location of the bright fringes.

$$\Delta\ell = \Delta\ell_1 + \Delta\ell_1 = d\left(\sin\phi + \sin\theta\right) = \pm m\lambda, \qquad m = 0,1,2,....$$

(*b*) The ± allows for the incident angle and the diffracted angle to have positive and negative values.

(*c*) We insert the given data, with *m*=1, to solve for the angles θ.

$$\theta = \sin^{-1}\left(-\sin\phi \pm \frac{m\lambda}{d}\right) = \sin^{-1}\left(-\sin 15° \pm \frac{550\times10^{-9}\,\text{m}}{0.01\,\text{m}/5000\,\text{lines}}\right) = \boxed{0.93° \text{ and } -32°}$$

46. Using Eq. 35-13 we calculate the maximum order possible for this diffraction grating, by setting the angle equal to 90°. Then we set the resolving power equal to the product of the number of grating lines and the order, where the resolving power is the wavelength divided by the minimum separation in wavelengths (Eq. 35-19) and solve for the separation.

$$\sin\theta = \frac{m\lambda}{d} \quad \rightarrow \quad m = \frac{d\sin\theta}{\lambda} = \frac{(0.01\,\text{m}/6500\,\text{lines})\sin 90°}{624\times10^{-9}\,\text{m}} = 2.47 \approx 2$$

$$\frac{\lambda}{\Delta\lambda} = Nm \;\Rightarrow\; \Delta\lambda = \frac{\lambda}{Nm} = \frac{624\text{ nm}}{(6500\text{ lines/cm})(3.18\text{ cm})(2)} = \boxed{0.015\text{ nm}}$$

The resolution is best for the second order, since it is more spread out than the first order.

47. (*a*) The resolving power is given by Eq. 35-19.

$$\text{R} = Nm \quad \rightarrow \quad \text{R}_1 = (16{,}000)(1) = \boxed{16{,}000} \;;\; \text{R}_1 = (16{,}000)(2) = \boxed{32{,}000}$$

(*b*) The wavelength resolution is also given by Eq. 35-19.

$$\text{R} = \frac{\lambda}{\Delta\lambda} = Nm \quad \rightarrow \quad \Delta\lambda = \frac{\lambda}{Nm}$$

$$\Delta\lambda_1 = \frac{410\,\text{nm}}{(16{,}000)(1)} = 2.6\times10^{-2}\,\text{nm} = \boxed{26\,\text{pm}} \;;\; \Delta\lambda_1 = \frac{410\,\text{nm}}{(32{,}000)(1)} = 1.3\times10^{-2}\,\text{nm} = \boxed{13\,\text{pm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

48. (*a*) We use Eq. 35-13, with the angle equal to 90° to determine the maximum order.

$$\sin\theta = \frac{m\lambda}{d} \quad \rightarrow \quad m = \frac{d\sin\theta}{\lambda} = \frac{(1050\,\text{nm})\sin 90°}{580\,\text{nm}} = 1.81$$

Since the order must be an integer number there will only be one principal maximum on either side of the central maximum. Counting the central maximum and the two other principal maxima there will be a total of three principal maxima.

(*b*) We use Eq. 35-17 to calculate the peak width, where the full peak width is double the half-peak width and the angle to the peak is given by Eq. 35-13.

$$\theta_0 = 0$$

$$\Delta\theta_0 = 2\frac{\lambda}{Nd\cos\theta_0} = \frac{2\lambda}{\ell\cos\theta_0} = \frac{2(580\,\text{nm})}{(1.80\times10^{-2}\,\text{m})\cos 0°} = 6.4\times10^{-5}\,\text{rad} = 0.0037°$$

$$\theta_{\pm1} = \sin^{-1}\left(\frac{m\lambda}{d}\right) = \sin^{-1}\left(\frac{\pm1\times580\,\text{nm}}{1050\,\text{nm}}\right) = \pm33.5°$$

$$\Delta\theta_{\pm1} = \frac{2\lambda}{\ell\cos\theta_{\pm1}} = \frac{2(580\,\text{nm})}{(1.80\times10^{-2}\,\text{m})\cos(\pm33.5°)} = 7.7\times10^{-5}\,\text{rad} = 0.0044°$$

49. We use Eq. 35-20, with $m = 1$.

$$m\lambda = 2d\sin\phi \quad \rightarrow \quad \phi = \sin^{-1}\frac{m\lambda}{2d} = \sin^{-1}\frac{(1)(0.138\,\text{nm})}{2(0.285\,\text{nm})} = 14.0°$$

50. We use Eq. 35-20 for X-ray diffraction.

(*a*) Apply Eq. 35-20 to both orders of diffraction.

$$m\lambda = 2d\sin\phi \quad \rightarrow \quad \frac{m_1}{m_2} = \frac{\sin\phi_1}{\sin\phi_2} \quad \rightarrow \quad \phi_2 = \sin^{-1}\left(\frac{m_2}{m_1}\sin\phi_1\right) = \sin^{-1}\left(\frac{2}{1}\sin 26.8°\right) = 64.4°$$

(*b*) Use the first order data.

$$m\lambda = 2d\sin\phi \quad \rightarrow \quad \lambda = \frac{2d\sin\phi}{m} = \frac{2(0.24\,\text{nm})\sin 26.8°}{1} = 0.22\,\text{nm}$$

51. For each diffraction peak, we can measure the angle and count the order. Consider Eq. 35-20.

$$m\lambda = 2d\sin\phi \quad \rightarrow \quad \lambda = 2d\sin\phi_1 \;;\; 2\lambda = 2d\sin\phi_2 \;;\; 3\lambda = 2d\sin\phi_3$$

From each equation, all we can find is the ratio $\frac{\lambda}{d} = 2\sin\phi = \sin\phi_2 = \frac{2}{3}\sin\phi_3$. No, we cannot separately determine the wavelength or the spacing.

52. Use Eq. 35-21. Since the initial light is unpolarized, the intensity after the first polarizer will be half the initial intensity. Let the initial intensity be I_0.

$$I_1 = \tfrac{1}{2}I_0 \;;\; I_2 = I_1\cos^2\theta = \tfrac{1}{2}I_0\cos^2\theta \quad \rightarrow \quad \frac{I_2}{I_0} = \frac{\cos^2 65°}{2} = 0.089$$

53. If I_0 is the intensity passed by the first Polaroid, the intensity passed by the second will be I_0 when the two axes are parallel. To calculate a reduction to half intensity, we use Eq. 35-21.

$$I = I_0\cos^2\theta = \tfrac{1}{2}I_0 \quad \rightarrow \quad \cos^2\theta = \tfrac{1}{2} \quad \rightarrow \quad \theta = 45°$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

54. We assume that the light is coming from air to glass, and use Eq. 35-22b.

$$\tan\theta_p = n_{glass} = 1.58 \quad \rightarrow \quad \theta_p = \tan^{-1} 1.58 = \boxed{57.7°}$$

55. The light is traveling from water to diamond. We use Eq. 35-22a.

$$\tan\theta_p = \frac{n_{diamond}}{n_{water}} = \frac{2.42}{1.33} = 1.82 \quad \rightarrow \quad \theta_p = \tan^{-1} 1.82 = \boxed{61.2°}$$

56. The critical angle exists when light passes from a material with a higher index of refraction (n_1) into a material with a lower index of refraction (n_2). Use Eq. 32-7.

$$\frac{n_2}{n_1} = \sin\theta_C = \sin 55°$$

To find the Brewster angle, use Eq. 35-22a. If light is passing from high index to low index, we have the following.

$$\frac{n_2}{n_1} = \tan\theta_p = \sin 55° \quad \rightarrow \quad \theta_p = \tan^{-1}(\sin 55°) = \boxed{39°}$$

If light is passing from low index to high index, we have the following.

$$\frac{n_1}{n_2} = \tan\theta_p = \frac{1}{\sin 55°} \quad \rightarrow \quad \theta_p = \tan^{-1}\left(\frac{1}{\sin 55°}\right) = \boxed{51°}$$

57. Let the initial intensity of the unpolarized light be I_0. The intensity after passing through the first Polaroid will be $I_1 = \frac{1}{2} I_0$. Then use Eq. 35-21.

$$I_2 = I_1 \cos^2\theta = \tfrac{1}{2} I_0 \cos^2\theta \quad \rightarrow \quad \theta = \cos^{-1}\sqrt{\frac{2I_2}{I_0}}$$

(*a*) $\theta = \cos^{-1}\sqrt{\dfrac{2I_2}{I_0}} = \cos^{-1}\sqrt{\dfrac{2}{3}} = \boxed{35.3°}$

(*b*) $\theta = \cos^{-1}\sqrt{\dfrac{2I_2}{I_0}} = \cos^{-1}\sqrt{\dfrac{2}{10}} = \boxed{63.4°}$

58. For the first transmission, the angle between the light and the polarizer is 18.0°. For the second transmission, the angle between the light and the polarizer is 36.0°. Use Eq. 35-21 twice.

$$I_1 = I_0 \cos^2 18.0° \ ; \ I_2 = I_1 \cos^2 36.0° = I_0 \cos^2 18.0° \cos^2 36.0° = 0.592 I_0$$

Thus the transmitted intensity is $\boxed{59.2\%}$ of the incoming intensity.

59. First case: the light is coming from water to air. Use Eq. 35-22a.

$$\tan\theta_p = \frac{n_{air}}{n_{water}} \quad \rightarrow \quad \theta_p = \tan^{-1}\frac{n_{air}}{n_{water}} = \tan^{-1}\frac{1.00}{1.33} = \boxed{36.9°}$$

Second case: for total internal reflection, the light must also be coming from water into air. Use Eq. 32-7.

$$\sin\theta_C = \frac{n_{air}}{n_{water}} \quad \rightarrow \quad \theta_p = \sin^{-1}\frac{n_{air}}{n_{water}} = \sin^{-1}\frac{1.00}{1.33} = \boxed{48.8°}$$

Third case: the light is coming from air to water. Use Eq. 35-22b.

$$\tan\theta_p = n_{water} \quad \rightarrow \quad \theta_p = \tan^{-1} n_{water} = \tan^{-1} 1.33 = \boxed{53.1°}$$

Note that the two Brewster's angles add to give 90.0°.

60. When plane-polarized light passes through a sheet oriented at an angle θ, the intensity decreases according to Eq. 35-21, $I = I_0 \cos^2\theta$. For $\theta = 45°$, $\cos^2\theta = \frac{1}{2}$. Thus sheets 2 through 6 will each reduce the intensity by a factor of $\frac{1}{2}$. The first sheet reduces the intensity of the unpolarized incident light by $\frac{1}{2}$ as well. Thus we have the following.

$$I = I_0\left(\tfrac{1}{2}\right)^6 = \boxed{0.016 I_0}$$

61. We assume vertically polarized light of intensity I_0 is incident upon the first polarizer. The angle between the polarization direction and the polarizer is θ. After the light passes that first polarizer, the angle between that light and the next polarizer will be $90° - \theta$. Apply Eq. 35-21.

$$I_1 = I_0 \cos^2\theta \;;\; I = I_1 \cos^2(90° - \theta) = I_0 \cos^2\theta \cos^2(90° - \theta) = \boxed{I_0 \cos^2\theta \sin^2\theta}$$

We can also use the trigonometric identity $\sin\theta\cos\theta = \frac{1}{2}\sin 2\theta$ to write the final intensity as

$I = I_0 \cos^2\theta \sin^2\theta = \boxed{\tfrac{1}{4} I_0 \sin^2 2\theta}$.

$$\frac{dI}{d\theta} = \frac{d}{d\theta}\left(\tfrac{1}{4} I_0 \sin^2 2\theta\right) = \tfrac{1}{4} I_0 (2\sin 2\theta)(\cos 2\theta) 2 = I_0 \sin 2\theta \cos 2\theta = \boxed{\tfrac{1}{2} I_0 \sin 4\theta}$$

$$\tfrac{1}{2} I_0 \sin 4\theta = 0 \;\rightarrow\; 4\theta = 0, 180°, 360° \;\rightarrow\; \theta = 0, 45°, 90°$$

Substituting the three angles back into the intensity equation, we see that the angles $0°$ and $90°$ both give minimum intensity. The angle $\boxed{45° \text{ gives the maximum intensity}}$ of $\frac{1}{4} I_0$.

62. We set the intensity of the beam as the sum of the maximum and minimum intensities. Using Eq. 35-21, we determine the intensity of the beam after it has passed through the polarizer. Since I_{min} is polarized perpendicular to I_{max} and the polarizer is rotated at an angle ϕ from the polarization of I_{max}, the polarizer is oriented at an angle of $(90° - \phi)$ from I_{min}.

$$I_0 = I_{max} + I_{min}$$

$$I = I_0 \cos^2\phi = I_{max} \cos^2\phi + I_{min} \cos^2(90 - \phi) = I_{max} \cos^2\phi + I_{min} \sin^2\phi$$

We solve the percent polarization equation for I_{min} and insert the result into our intensity equation.

$$p = \frac{I_{max} - I_{min}}{I_{max} + I_{min}} \;\rightarrow\; I_{min} = \frac{1-p}{1+p} I_{max}$$

$$I = I_{max} \cos^2\phi + \left(\frac{1-p}{1+p} I_{max}\right)\sin^2\phi = I_{max}\left[\frac{(1+p)\cos^2\phi + (1-p)\sin^2\phi}{1+p}\right]$$

$$= I_{max}\left[\frac{(\cos^2\phi + \sin^2\phi) + p(\cos^2\phi - \sin^2\phi)}{1+p}\right] = \boxed{I_{max}\left[\frac{1 + p\cos 2\phi}{1+p}\right]}$$

63. Because the width of the pattern is much smaller than the distance to the screen, the angles from the diffraction pattern for this first order will be small. Thus we may make the approximation that $\sin\theta = \tan\theta$. We find the angle to the first minimum from the distances, using half the width of the full first order pattern. Then we use Eq. 35-2 to find the slit width.

$$\tan\theta_{1\,min} = \tfrac{1}{2}\frac{(8.20\,\text{cm})}{(285\,\text{cm})} = 0.01439 = \sin\theta_{1\,min}$$

$$D\sin\theta = m\lambda \;\rightarrow\; D = \frac{m\lambda}{\sin\theta} = \frac{(1)(415\,\text{nm})}{0.01439} = 2.88\times10^4\,\text{nm} = \boxed{2.88\times10^{-5}\,\text{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

64. If the original intensity is I_0, the first polarizers will reduce the intensity to one half the initial intensity, or $I_1 = \frac{1}{2} I_0$. Each subsequent polarizer oriented at an angle θ to the preceding one will reduce the intensity by $\cos^2\theta$, as given by Eq. 35-21. We set the final intensity equal to one quarter of the initial intensity, with $\theta = 10°$ for each polarizer and solve for the minimum number of polarizers.

$$I = \tfrac{1}{2} I_0 \left(\cos^2\theta\right)^{n-1} \;\Rightarrow\; n = 1 + \frac{\ln\left(2I/I_0\right)}{\ln\left(\cos^2\theta\right)} = 1 + \frac{\ln\left(2\times 0.25\right)}{\ln\left(\cos^2 10°\right)} = 23.6 \approx \boxed{24 \text{ polarizers}}$$

We round the number of lenses up to the integer number of polarizers, so that the intensity will be less than 25% of the initial intensity.

65. The lines act like a grating. We assume that we see the first diffractive order, so $m = 1$. Use Eq. 35-13.

$$d\sin\theta = m\lambda \;\rightarrow\; d = \frac{m\lambda}{\sin\theta} = \frac{(1)(480\,\text{nm})}{\sin 56°} = \boxed{580\,\text{nm}}$$

66. We assume the sound is diffracted when it passes through the doorway, and find the angles of the minima from Eq. 35-2.

$$\lambda = \frac{v}{f} \;;\; D\sin\theta = m\lambda = \frac{mv}{f} \;\rightarrow\; \theta = \sin^{-1}\frac{mv}{Df},\; m = 1,\, 2,\, 3,\, \ldots$$

$$m = 1:\;\; \theta = \sin^{-1}\frac{mv}{Df} = \sin^{-1}\frac{(1)(340\,\text{m/s})}{(0.88\,\text{m})(850\,\text{Hz})} = \boxed{27°}$$

$$m = 2:\;\; \theta = \sin^{-1}\frac{mv}{Df} = \sin^{-1}\frac{(2)(340\,\text{m/s})}{(0.88\,\text{m})(850\,\text{Hz})} = \boxed{65°}$$

$$m = 3:\;\; \theta = \sin^{-1}\frac{mv}{Df} = \sin^{-1}\frac{(3)(340\,\text{m/s})}{(0.88\,\text{m})(850\,\text{Hz})} = \sin^{-1} 1.36 = \text{impossible}$$

Thus the whistle would not be heard clearly at angles of $\boxed{27° \text{ and } 65° \text{ on either side of the normal.}}$

67. We find the angles for the first order from Eq. 35-13.

$$\theta_1 = \sin^{-1}\frac{m\lambda}{d} = \sin^{-1}\frac{(1)\left(4.4\times 10^{-7}\ \text{m}\right)}{0.01\ \text{m}/7600} = 19.5°$$

$$\theta_2 = \sin^{-1}\frac{(1)\left(6.8\times 10^{-7}\ \text{m}\right)}{0.01\ \text{m}/7600} = 31.1°$$

The distances from the central white line on the screen are found using the tangent of the angle and the distance to the screen.

$$y_1 = L\tan\theta_1 = (2.5\,\text{m})\tan 19.5° = 0.89\,\text{m}$$

$$y_2 = L\tan\theta_2 = (2.5\,\text{m})\tan 31.1° = 1.51\,\text{m}$$

Subtracting these two distances gives the linear separation of the two lines.

$$y_2 - y_1 = 1.51\,\text{m} - 0.89\,\text{m} = \boxed{0.6\,\text{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

68. Because the angle increases with wavelength, to miss a complete order we use the smallest visible wavelength, 400 nm. The maximum angle is 90°. With these parameters we use Eq. 35-13 to find the slit separation, *d*. The inverse of the slit separation gives the number of lines per unit length.

$$d\sin\theta = m\lambda \;\rightarrow\; d = \frac{m\lambda}{\sin\theta} = \frac{2(400\,\text{nm})}{\sin 90°} = \boxed{800\,\text{nm}}$$

$$\frac{1}{d} = \frac{1}{800\times10^{-7}\,\text{cm}} = \boxed{12{,}500\,\text{lines/cm}}$$

69. We find the angles for the two first-order peaks from the distance to the screen and the distances along the screen to the maxima from the central peak.

$$\tan\theta_1 = \frac{y_1}{\ell} \;\rightarrow\; \theta_1 = \tan^{-1}\frac{y_1}{\ell} = \tan^{-1}\frac{(3.32\,\text{cm})}{(66.0\,\text{cm})} = 2.88°$$

$$\tan\theta_2 = \frac{y_2}{\ell} \;\rightarrow\; \theta_2 = \tan^{-1}\frac{y_2}{\ell} = \tan^{-1}\frac{(3.71\,\text{cm})}{(66.0\,\text{cm})} = 3.22°$$

Inserting the wavelength of yellow sodium light and the first order angle into Eq. 35-13, we calculate the separation of lines. Then, using the separation of lines and the second angle, we calculate the wavelength of the second source. Finally, we take the inverse of the line separation to determine the number of lines per centimeter on the grating.

$$d\sin\theta_1 = m\lambda_1 \;\rightarrow\; d = \frac{m\lambda_1}{\sin\theta_1} = \frac{1(589\text{ nm})}{\sin 2.88°} = 11{,}720\,\text{nm}$$

$$\lambda_2 = \frac{d\sin\theta_1}{m} = (11{,}720\,\text{nm})\sin 3.22° = \boxed{658\,\text{nm}}$$

$$\frac{1}{d} = \frac{1\text{ line}}{11{,}720\times10^{-7}\,\text{cm}} = \boxed{853\,\text{lines/cm}}$$

70. We find the angles for the first order from Eq. 35-13, with $m = 1$. The slit spacing is the inverse of the lines/cm of the grating.

$$d = \frac{1}{8100\,\text{lines/cm}}\times\frac{1\,\text{m}}{100\,\text{cm}} = \frac{1}{8.1\times10^5}\,\text{m} \;;\; d\sin\theta = m\lambda \;\rightarrow\; \theta = \sin^{-1}\frac{m\lambda}{d} \;\rightarrow$$

$$\Delta\theta = \sin^{-1}\frac{\lambda_1}{d} - \sin^{-1}\frac{\lambda_2}{d} = \sin^{-1}\frac{656\times10^{-9}\,\text{m}}{\left(\frac{1}{8.1\times10^5}\,\text{m}\right)} - \sin^{-1}\frac{410\times10^{-9}\,\text{m}}{\left(\frac{1}{8.1\times10^5}\,\text{m}\right)} = \boxed{13°}$$

71. (*a*) This is very similar to Example 35-6. We use the same notation as in that Example, and solve for the distance ℓ.

$$s = \ell\theta = \ell\frac{1.22\lambda}{D} \;\rightarrow\; \ell = \frac{Ds}{1.22\lambda} = \frac{(6.0\times10^{-3}\,\text{m})(2.0\,\text{m})}{1.22(560\times10^{-9}\,\text{m})} = \boxed{1.8\times10^4\,\text{m}} = 18\,\text{km}$$

(*b*) We use the same data for the eye and the wavelength.

$$\theta = \frac{1.22\lambda}{D} = \frac{1.22(560\times10^{-9}\,\text{m})}{(6.0\times10^{-3}\,\text{m})} = 1.139\times10^{-4}\,\text{rad}\left(\frac{180°}{\pi\,\text{rad}}\right)\left(\frac{3600''}{1°}\right) = \boxed{23''}$$

Our answer is less than the real resolution, because of atmospheric effects and aberrations in the eye.

72. We first find the angular half-width for the first order, using Eq. 35-1, $\sin\theta = \dfrac{\lambda}{D}$. Since this angle is small, we may use the approximation that $\sin\theta \approx \tan\theta$. The width from the central maximum to the first minimum is given by $y = L\tan\theta$. That width is then doubled to find the width of the beam, from the first diffraction minimum on one side to the first diffraction minimum on the other side.

$$y = L\tan\theta = L\sin\theta$$

$$\Delta y = 2y = 2L\sin\theta = 2L\frac{\lambda}{D} = \frac{2\left(3.8\times10^{8}\,\text{m}\right)\left(633\times10^{-9}\,\text{m}\right)}{0.010\,\text{m}} = \boxed{4.8\times10^{4}\,\text{m}}$$

73. The distance between lines on the diffraction grating is found by solving Eq. 35-13 for *d*, the grating spacing. The number of lines per meter is the reciprocal of *d*.

$$d = \frac{m\lambda}{\sin\theta} \quad\rightarrow\quad \frac{1}{d} = \frac{\sin\theta}{m\lambda} = \frac{\sin 21.5^\circ}{(1)6.328\times10^{-7}\,\text{m}} = \boxed{5.79\times10^{5}\,\text{lines/m}}$$

74. (*a*) We calculate the wavelength of the mother's sound by dividing the speed of sound by the frequency of her voice. We use Eq. 34-2b to determine the double slit interference minima with $d = 3.0$ m.

$$\lambda = v/f = \left(340\,\text{m/s}\right)/\left(400\,\text{Hz}\right) = 0.85\,\text{m}$$

$$\theta = \sin^{-1}\left[\frac{\left(m+\tfrac{1}{2}\right)\lambda}{d}\right] = \sin^{-1}\left[\frac{\left(m+\tfrac{1}{2}\right)(0.85\,\text{m})}{(3.0\,\text{m})}\right] = \sin^{-1}\left[0.2833\left(m+\tfrac{1}{2}\right)\right],\ m = 0,1,2,...$$

$$= \boxed{8.1^\circ,\ 25^\circ,\ 45^\circ,\ \text{and}\ 83^\circ}$$

We use Eq. 35-2 to determine the angles for destructive interference from single slit diffraction, with $D = 1.0$ m.

$$\theta = \sin^{-1}\left[\frac{m\lambda}{D}\right] = \sin^{-1}\left[\frac{m(0.85\,\text{m})}{(1.0\,\text{m})}\right] = \sin^{-1}\left[0.85m\right],\ m = 1,2,...$$

$$\theta = \boxed{58^\circ}$$

(*b*) We use the depth and length of the room to determine the angle the sound would need to travel to reach the son.

$$\theta = \tan^{-1}\left(\frac{8.0\,\text{m}}{5.0\,\text{m}}\right) = 58^\circ$$

This angle is close to the single slit diffraction minimum, so the son has a good explanation for not hearing her.

75. We use the Brewster angle, Eq. 35-22b, for light coming from air to water.

$$\tan\theta_\text{p} = n \quad\rightarrow\quad \theta_\text{p} = \tan^{-1}n = \tan^{-1}1.33 = 53.1^\circ$$

This is the angle from the normal, as seen in Fig. 35-41, so the angle above the horizontal is the complement of $90.0^\circ - 53.1^\circ = \boxed{36.9^\circ}$.

76. (*a*) Let the initial unpolarized intensity be I_0. The intensity of the polarized light after passing the first polarizer is $I_1 = \frac{1}{2}I_0$. Apply Eq. 35-21 to find the final intensity.

$$I_2 = I_1\cos^2\theta = I_1\cos^2 90^\circ = \boxed{0}.$$

(*b*) Now the third polarizer is inserted. The angle between the first and second polarizers is 66°, so the angle between the second and third polarizers is 24°. It is still true that $I_1 = \frac{1}{2}I_0$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$I_2 = I_1 \cos^2 66° = \tfrac{1}{2} I_0 \cos^2 66° \;\; ; \;\; I_3 = I_2 \cos^2 24° = \tfrac{1}{2} I_0 \cos^2 66° \cos^2 24° = 0.069 \;\; \rightarrow$$

$$\frac{I_3}{I_1} = \boxed{0.069}$$

(*c*) The two crossed polarizers, which are now numbers 2 and 3, will still not allow any light to pass through them if they are consecutive to each other. Thus $\frac{I_3}{I_1} = \boxed{0}$.

77. The reduction being investigated is that which occurs when the polarized light passes through the second Polaroid. Let I_1 be the intensity of the light that emerges from the first Polaroid, and I_2 be the intensity of the light after it emerges from the second Polaroid. Use Eq. 35-21.

(*a*) $I_2 = I_1 \cos^2 \theta = 0.25 I_1 \;\; \rightarrow \;\; \theta = \cos^{-1} \sqrt{0.25} = \boxed{60°}$

(*b*) $I_2 = I_1 \cos^2 \theta = 0.10 I_1 \;\; \rightarrow \;\; \theta = \cos^{-1} \sqrt{0.10} = \boxed{72°}$

(*c*) $I_2 = I_1 \cos^2 \theta = 0.010 I_1 \;\; \rightarrow \;\; \theta = \cos^{-1} \sqrt{0.010} = \boxed{84°}$

78. (*a*) We apply Eq. 35-21 through the successive polarizers. The initial light is unpolarized. Each polarizer is then rotated $30°$ from the previous one.

$$I_1 = \tfrac{1}{2} I_0 \;\; ; \;\; I_2 = I_1 \cos^2 \theta_2 = \tfrac{1}{2} I_0 \cos^2 \theta_2 \;\; ; \;\; I_3 = I_2 \cos^2 \theta_3 = \tfrac{1}{2} I_0 \cos^2 \theta_2 \cos^2 \theta_3 \;\; ;$$

$$I_4 = I_3 \cos^2 \theta_4 = \tfrac{1}{2} I_0 \cos^2 \theta_2 \cos^2 \theta_3 \cos^2 \theta_4 = \tfrac{1}{2} I_0 \cos^2 30° \cos^2 30° \cos^2 30° = \boxed{0.21 I_0}$$

(*b*) If we remove the second polarizer, then the angle between polarizers # 1 and # 3 is now $60°$.

$$I_1 = \tfrac{1}{2} I_0 \;\; ; \;\; I_3 = I_1 \cos^2 \theta_3 = \tfrac{1}{2} I_0 \cos^2 \theta_3 \;\; ;$$

$$I_4 = I_3 \cos^2 \theta_4 = \tfrac{1}{2} I_0 \cos^2 \theta_3 \cos^2 \theta_4 = \tfrac{1}{2} I_0 \cos^2 60° \cos^2 30° = 0.094 I_0$$

The same value would result by removing the third polarizer, because then the angle between polarizers # 2 and # 4 would be $60°$. Thus we can decrease the intensity by removing either the second or third polarizer.

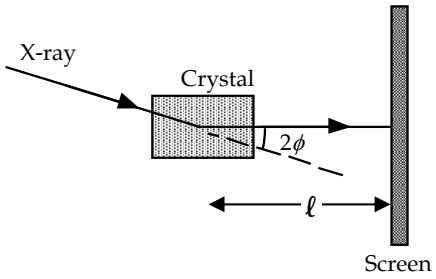
(*c*) If we remove both the second and third polarizers, we will have two polarizers with their axes perpendicular, so no light will be transmitted.

79. For the minimum aperture the angle subtended at the lens by the smallest feature is the angular resolution, given by Eq. 35-10. We let ℓ represent the spatial separation, and r represent the altitude of the camera above the ground.

$$\theta = \frac{1.22\lambda}{D} = \frac{\ell}{r} \;\; \rightarrow \;\; D = \frac{1.22\lambda r}{\ell} = \frac{1.22\left(580 \times 10^{-9}\,\text{m}\right)\left(25000\,\text{m}\right)}{\left(0.05\,\text{m}\right)} = 0.3538\,\text{m} \approx \boxed{0.4\,\text{m}}$$

80. Let I_0 be the initial intensity. Use Eq. 35-21 for both transmissions of the light.

$$I_1 = I_0 \cos^2 \theta_1 \;\; ; \;\; I_2 = I_1 \cos^2 \theta_2 = I_0 \cos^2 \theta_1 \cos^2 \theta_2 = 0.25 I_0 \;\; \rightarrow$$



$$\theta_1 = \cos^{-1}\left(\frac{\sqrt{0.25}}{\cos\theta_2}\right) = \cos^{-1}\left(\frac{\sqrt{0.25}}{\cos 48°}\right) = \boxed{42°}$$

81. We find the spacing from Eq. 35-20.

$$m\lambda = 2d \sin\phi \;\; \rightarrow \;\; d = \frac{m\lambda}{2\sin\phi} = \frac{(2)\left(9.73 \times 10^{-11}\,\text{m}\right)}{2\sin 23.4°} = \boxed{2.45 \times 10^{-10}\,\text{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

82. The angles for Bragg scattering are found from Eq. 35-20, for $m = 1$ and $m = 2$. If the distance from the crystal to the screen is ℓ, the radius of the diffraction ring is given by $r = \ell \tan 2\phi$.

$$2d\sin\phi = m\lambda \;\; ; \;\; r = \ell\tan 2\phi = \ell\tan\left[2\sin^{-1}\left(\frac{m\lambda}{2d}\right)\right]$$

$$r_1 = \ell\tan\left[2\sin^{-1}\left(\frac{m\lambda}{2d}\right)\right]$$

$$= (0.12\,\text{m})\tan\left[2\sin^{-1}\left(\frac{(1)(0.10\times10^{-9}\,\text{m})}{2(0.22\times10^{-9}\,\text{m})}\right)\right] = \boxed{0.059\,\text{m}}$$

$$r_2 = \ell\tan\left[2\sin^{-1}\left(\frac{m\lambda}{2d}\right)\right] = (0.12\,\text{m})\tan\left[2\sin^{-1}\left(\frac{(2)(0.10\times10^{-9}\,\text{m})}{2(0.22\times10^{-9}\,\text{m})}\right)\right] = \boxed{0.17\,\text{m}}$$

83. From Eq. 35-10 we calculate the minimum resolvable separation angle. We then multiply this angle by the distance between the Earth and Moon to obtain the minimum distance between two objects on the Moon that the Hubble can resolve.

$$\theta = \frac{1.22\lambda}{D} = \frac{1.22(550\times10^{-9}\,\text{m})}{2.4\,\text{m}} = 2.796\times10^{-7}\,\text{rad}$$

$$\ell = s\theta = (3.84\times10^{8}\,\text{m})(2.796\times10^{-7}\,\text{rad}) = \boxed{110\,\text{m}}$$

84. From Eq. 35-10 we calculate the minimum resolvable separation angle. We then multiply this angle by the distance between Mars and Earth to obtain the minimum distance between two objects that can be resolved by a person on Mars

$$\theta = \frac{1.22\lambda}{D} = \frac{1.22(550\times10^{-9}\ \text{m})}{0.005\ \text{m}} = 1.34\times10^{-4}\ \text{rad}$$

$$\ell = s\theta = (8\times10^{10}\ \text{m})(1.34\times10^{-4}\ \text{rad}) = \boxed{1.07\times10^{7}\ \text{m}}$$

Since the minimum resolvable distance is much less than the Earth-Moon distance, a person standing on Mars could resolve the Earth and Moon as two separate objects without a telescope.

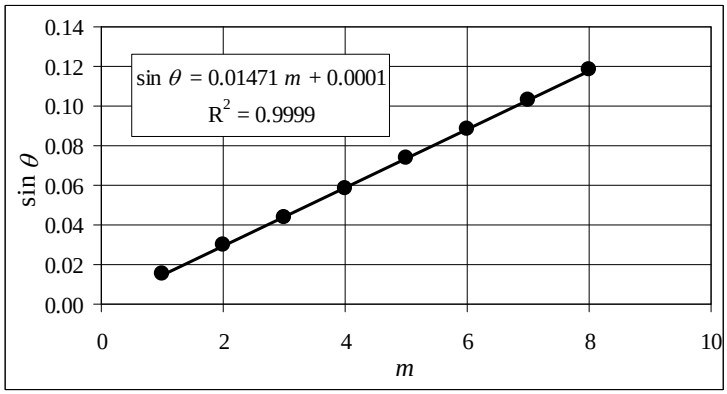
85. The distance x is twice the distance to the first minima. We can write x in terms of the slit width D using Eq. 35-2, with $m = 1$. The ratio $\frac{\lambda}{D}$ is small, so we may approximate $\sin\theta \approx \tan\theta \approx \theta$.

$$\sin\theta = \frac{\lambda}{D} \approx \theta \;\; ; \;\; x = 2y = 2\ell\tan\theta = 2\ell\theta = 2\ell\frac{\lambda}{D}$$

When the plate is heated up the slit width increases due to thermal expansion. Eq. 17-1b is used to determine the new slit width, with the coefficient of thermal expansion, α, given in Table 17-1. Each slit width is used to determine a value for x. Subtracting the two values for x gives the change Δx. We use the binomial expansion to simplify the evaluation.

$$\Delta x = x - x_0 = 2\ell\left(\frac{\lambda}{D_0(1+\alpha\Delta T)}\right) - 2\ell\left(\frac{\lambda}{D_0}\right) = \frac{2\ell\lambda}{D_0}\left(\frac{1}{(1+\alpha\Delta T)} - 1\right) = \frac{2\ell\lambda}{D_0}\left((1+\alpha\Delta T)^{-1} - 1\right)$$

$$= \frac{2\ell\lambda}{D_0}(1-\alpha\Delta T - 1) = -\frac{2\ell\lambda}{D_0}\alpha\Delta T = -\frac{2(2.0\,\text{m})(650\times10^{-9}\,\text{m})}{(22\times10^{-6}\,\text{m})}\left[25\times10^{-6}\,(\text{C}^\circ)^{-1}\right](55\text{C}^\circ)$$



$$= \boxed{-1.7\times10^{-4}\,\text{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

86. The tangent of the angle for each order is the distance in the table divided by the distance to the screen. If we call the distance in the table y and the distance to the screen ℓ, then we have this relationship.

$$\tan\theta = \frac{y}{\ell} \quad \rightarrow \quad \theta = \tan^{-1}\frac{y}{\ell}$$

The relationship between the angle and the wavelength is given by Eq. 35-2, $D\sin\theta = m\lambda$, which can be written as $\sin\theta = \dfrac{\lambda}{D}m$. A plot of $\sin\theta$ vs. m should have a slope of $\dfrac{\lambda}{D}$, and so the wavelength can be determined from the slope and the slit width. The graph is shown, and the slope used to calculate the wavelength.

$$\frac{\lambda}{D} = \text{slope} \quad \rightarrow \quad \lambda = (\text{slope})D = (0.01471)\left(4.000\times10^{-5}\,\text{m}\right) = \boxed{588.4\,\text{nm}}$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH35.XLS," on tab "Problem 35.86."

87. We have N polarizers providing a rotation of $90°$. Thus, each polarizer must rotate the light by an angle of $\theta_N = (90/\text{N})°$. As the light passes through each polarizer, the intensity will be reduced by a factor of $\cos^2\theta_N$. Let the original intensity be I_0.

$$I_1 = I_0\cos^2\theta_N \;;\; I_2 = I_1\cos^2\theta_N = I_0\cos^4\theta_N \;;\; I_3 = I_2\cos^2\theta_N = I_0\cos^6\theta_N$$

$$I_N = I_0(\cos\theta_N)^{2N} = 0.90I_0 \quad \rightarrow \quad \left[\cos(90°/\text{N})\right]^{2N} = 0.90$$

We evaluate $\left[\cos(90°/\text{N})\right]^{2N}$ for various values of N. A table for a few values of N is shown here. We see that N = 24 satisfies the criteria, and so $\theta_N = (90/24\text{N})° = (90/24\text{N})° = 3.75°$. So we need to put 24 polarizers in the path of the original polarized light, each rotated $3.75°$ from the previous one.

N	$[\cos(90/N)]^{2N}$
21	0.8890
22	0.8938
23	0.8982
24	0.9022
25	0.9060

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH35.XLS," on tab "Problem 35.87."

88. (*a*) The intensity of the diffraction pattern is given by Eqs. 35-6 and 35-7. We want to find the angle where $I = \frac{1}{2}I_0$. Doubling this angle will give the desired $\Delta\theta$.

$$I_\theta = I_0\left(\frac{\sin\beta/2}{\beta/2}\right)^2 = \tfrac{1}{2}I_0 \quad \rightarrow \quad \sin\beta/2 = \frac{\beta/2}{\sqrt{2}} \text{ or } \sin\alpha = \frac{\alpha}{\sqrt{2}}, \text{ with } \alpha = \tfrac{1}{2}\beta$$

This equation must be solved numerically. A spreadsheet was developed to find the non-zero values of α that satisfy $\sin\alpha - \dfrac{\alpha}{\sqrt{2}} = 0$. It is apparent from this expression that there will be no solutions for $\alpha > \sqrt{2}$. The only non-zero value is $\alpha = 1.392$. Now use Eq. 35-6 to find θ.

$$\beta = \frac{2\pi}{\lambda}D\sin\theta \quad \rightarrow \quad \theta = \sin^{-1}\frac{\lambda\beta}{2\pi D} = \sin^{-1}\frac{2\lambda\alpha}{2\pi D} = \sin^{-1}\frac{\lambda(1.392)}{\pi D} \;;$$

$$\Delta\theta = 2\theta = \boxed{2\sin^{-1}\frac{\lambda(1.392)}{\pi D}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) For $D = \lambda$: $\Delta\theta = 2\sin^{-1}\dfrac{\lambda(1.392)}{\pi D} = 2\sin^{-1}\dfrac{(1.392)}{\pi} = \boxed{52.6°}$

For $D = 100\lambda$: $\Delta\theta = 2\sin^{-1}\dfrac{\lambda(1.392)}{\pi D} = 2\sin^{-1}\dfrac{(1.392)}{100\pi} = \boxed{0.508°}$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH35.XLS," on tab "Problem 35.88."

CHAPTER 36: The Special Theory of Relativity

Responses to Questions

1. No. The train is an inertial reference frame, and the laws of physics are the same in all inertial reference frames, so there is no experiment you can perform inside the train car to determine if you are moving.

2. The fact that you instinctively think you are moving is consistent with the relativity principle applied to mechanics. Even though you are at rest relative to the ground, when the car next to you creeps forward, you are moving backward relative to that car.

3. As long as the railroad car is traveling with a constant velocity, the ball will land back in his hand.

4. The relativity principle refers only to inertial reference frames. Neither the reference frame of the Earth nor the reference frame of the Sun is inertial. Either reference frame is valid, but the laws of physics will not be the same in each of the frames.

5. The starlight would pass at c, regardless of your spaceship's speed. This is consistent with the second postulate of relativity which states that the speed of light through empty space is independent of the speed of the source or the observer.

6. It deals with space-time (sometimes called "the fabric of space-time") and the actual passage of time in the reference frame, not with the mechanical workings of clocks. Any measurement of time (heartbeats or decay rates, for instance) would be measured as slower than normal when viewed by an observer outside the moving reference frame.

7. Time *actually* passes more slowly in the moving reference frames, according to observers outside the moving frames.

8. This situation is an example of the "twin paradox" applied to parent-child instead of to twins. This might be possible if the woman was traveling at high enough speeds during her trip. Time would have passed more slowly for her and she could have aged less than her son, who stayed on Earth. (Note that the situations of the woman and son are not symmetric; she must undergo acceleration during her journey.)

9. No, you would not notice any change in your heartbeat, mass, height, or waistline, because you are in the inertial frame of the spaceship. Observers on Earth, however, would report that your heartbeat is slower and your mass greater than if you were at rest with respect to them. Your height and waistline will depend on your orientation with respect to the motion. If you are "standing up" in the spaceship such that your height is perpendicular to the direction of travel, then your height would not change but your waistline would shrink. If you happened to be "lying down" so that your body is parallel to the direction of motion when the Earth observers peer through the telescope, then you would appear shorter but your waistline would not change.

10. Yes. However, at a speed of only 90 km/hr, v/c is very small, and therefore γ is very close to one, so the effects would not be noticeable.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

11. Length contraction and time dilation would not occur. If the speed of light were infinite, v/c would be zero for all finite values of v, and therefore γ would always be one, resulting in $\Delta t = \Delta t_0$ and $\ell = \ell_0$.

12. The effects of special relativity, such as time dilation and length contraction, would be noticeable in our everyday activities because everyday speeds would no longer be so small compared to the speed of light. There would be no "absolute time" on which we would all agree, so it would be more difficult, for instance, to plan to meet friends for lunch at a certain time! In addition, 25 m/s would be the limiting speed and nothing in the universe would move faster than that.

13. Both the length contraction and time dilation formulas include the term $\sqrt{1 - v^2/c^2}$. If c were not the limiting speed in the universe, then it would be possible to have a situation with $v > c$. However, this would result in a negative number under the square root, which gives an imaginary number as a result, indicating that c must be the limiting speed.

14. Mr. Tompkins appears shrunk in the horizontal direction, since that is the direction of his motion, and normal size in the vertical direction, perpendicular to his direction of motion. This length contraction is a result of the fact that, to the people on the sidewalk, Mr. Tompkins is in a moving frame of reference. If the speed of light were only 20 mi/h, then the amount of contraction, which depends on γ, would be enough to be noticeable. Therefore, Mr. Tompkins and his bicycle appear very skinny. (Compare to the chapter-opening figure, which is shown from Mr. Tompkin's viewpoint. In this case, Mr. Tompkins sees himself as "normal" but all the objects moving with respect to him are contracted.)

15. No. The relativistic momentum of the electron is given by $p = \gamma mv = \dfrac{mv}{\sqrt{1 - v^2/c^2}}$. At low speeds (compared to c) this reduces to the classical momentum, $p = mv$. As v approaches c, γ approaches infinity so there is no upper limit to the electron's momentum.

16. No. To accelerate a particle with nonzero rest mass up to the speed of light would require an infinite amount of energy, and so is not possible.

17. No. $E = mc^2$ does not conflict with the principle of conservation of energy as long as it is understood that mass is a form of energy.

18. Yes, mass is a form of energy so technically it is correct to say that a spring has more mass when compressed. However, the change in mass of the spring is very small and essentially negligible.

19. "Energy can be neither created nor destroyed." Mass is a form of energy, and mass can be "destroyed" when it is converted to other forms of energy. The total amount of energy remains constant.

20. Technically yes, the notion that velocities simply add is wrong. However, at everyday speeds, the relativistic equations reduce to classical ones, so our ideas about velocity addition are essentially true for velocities that are low compared to the speed of light.

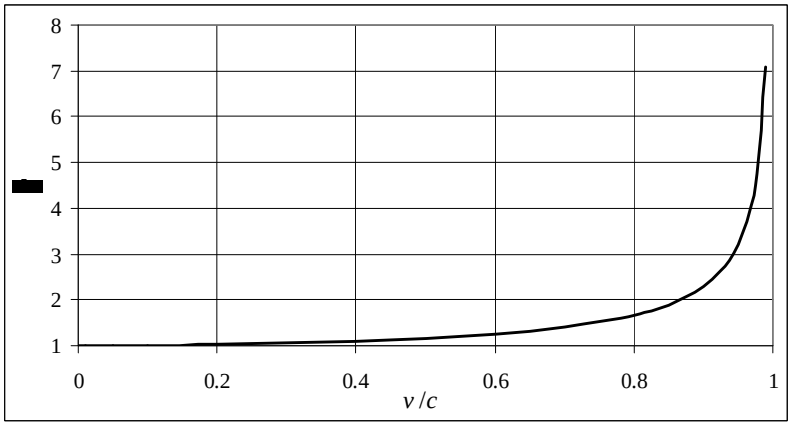
Solutions to Problems



1. You measure the contracted length. Find the rest length from Eq. 36-3a.

$$\ell_0 = \frac{\ell}{\sqrt{1-v^2/c^2}} = \frac{38.2\,\text{m}}{\sqrt{1-(0.850)^2}} = \boxed{72.5\,\text{m}}$$

2. We find the lifetime at rest from Eq. 36-1a.

$$\Delta t_0 = \Delta t\sqrt{1-v^2/c^2} = \left(4.76\times10^{-6}\,\text{s}\right)\sqrt{1-\left(\frac{2.70\times10^8\,\text{m/s}}{3.00\times10^8\,\text{m/s}}\right)^2} = \boxed{2.07\times10^{-6}\,\text{s}}$$

3. The numerical values and graph were generated in a spreadsheet. The graph is shown also. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH36.XLS," on tab "Problem 36.3."

v/c	0.00	0.01	0.05	0.10	0.20	0.30	0.40	0.50	0.60	0.70	0.80	0.90	0.99
γ	1.000	1.000	1.001	1.005	1.021	1.048	1.091	1.155	1.250	1.400	1.667	2.294	7.089

4. The measured distance is the contracted length. Use Eq. 36-3a.

$$\ell = \ell_0\sqrt{1-v^2/c^2} = (135\text{ ly})\sqrt{1-\left(\frac{2.80\times10^8\,\text{m/s}}{3.00\times10^8\,\text{m/s}}\right)^2} = \boxed{48.5\text{ ly}}$$

5. The speed is determined from the time dilation relationship, Eq. 36-1a.

$$\Delta t_0 = \Delta t\sqrt{1-v^2/c^2} \quad \rightarrow$$

$$v = c\sqrt{1-\left(\frac{\Delta t_0}{\Delta t}\right)^2} = c\sqrt{1-\left(\frac{2.60\times10^{-8}\,\text{s}}{4.40\times10^{-8}\,\text{s}}\right)^2} = \boxed{0.807c} = 2.42\times10^8\,\text{m/s}$$

6. The speed is determined from the length contraction relationship, Eq. 36-3a.

$$\ell = \ell_0\sqrt{1-v^2/c^2} \quad \rightarrow \quad v = c\sqrt{1-\left(\frac{\ell}{\ell_0}\right)^2} = c\sqrt{1-\left(\frac{35\text{ly}}{56\text{ly}}\right)^2} = \boxed{0.78c} = 2.3\times10^8\,\text{m/s}$$

7. The speed is determined from the length contraction relationship, Eq. 36-3a. Then the time is found from the speed and the contracted distance.

$$\ell = \ell_0\sqrt{1-v^2/c^2} \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$v = c\sqrt{1-\left(\frac{\ell}{\ell_0}\right)^2} \;;\; t = \frac{\ell}{v} = \frac{\ell}{c\sqrt{1-\left(\frac{\ell}{\ell_0}\right)^2}} = \frac{25\text{ly}}{c\sqrt{1-\left(\frac{25\text{ly}}{65\text{ly}}\right)^2}} = \frac{(25\text{y})c}{c(0.923)} = \boxed{27\text{y}}$$

8. The speed is determined from the length contraction relationship, Eq. 36-3a.

$$\ell = \ell_0\sqrt{1-v^2/c^2} \;\rightarrow\; v = c\sqrt{1-\left(\frac{\ell}{\ell_0}\right)^2} = c\sqrt{1-(0.900)^2} = \boxed{0.436c}$$

9. The change in length is determined from the length contraction relationship, Eq. 36-3a. The speed is very small compared to the speed of light.

$$\ell = \ell_0\sqrt{1-v^2/c^2} \;\rightarrow$$

$$\frac{\ell}{\ell_0} = \sqrt{1-v^2/c^2} = \left(1-\frac{v^2}{c^2}\right)^{1/2} \approx 1-\tfrac{1}{2}\frac{v^2}{c^2} = 1-\tfrac{1}{2}\left(\frac{11.2\times10^3\text{ m/s}}{3.00\times10^8\text{ m/s}}\right)^2 = 1-6.97\times10^{-10}$$

So the percent decrease is $\boxed{\left(6.97\times10^{-8}\right)\%}$.

10. (*a*) The measured length is the contracted length. We find the rest length from Eq. 36-3a.

$$\ell_0 = \frac{\ell}{\sqrt{1-v^2/c^2}} = \frac{4.80\text{ m}}{\sqrt{1-(0.760)^2}} = \boxed{7.39\text{ m}}$$

Distances perpendicular to the motion do not change, so the rest height is $\boxed{1.35\text{m}}$.

(*b*) The time in the spacecraft is the rest time, found from Eq. 36-1a.

$$\Delta t_0 = \Delta t\sqrt{1-v^2/c^2} = (20.0\text{s})\sqrt{1-(0.760)^2} = \boxed{13.0\text{s}}$$

(*c*) To your friend, you moved at the same relative speed: $\boxed{0.760c}$.

(*d*) She would measure the same time dilation: $\boxed{13.0\text{s}}$.

11. (*a*) We use Eq. 36-3a for length contraction with the contracted length 99.0% of the rest length.

$$\ell = \ell_0\sqrt{1-v^2/c^2} \;\rightarrow\; v = c\sqrt{1-\left(\frac{\ell}{\ell_0}\right)^2} = c\sqrt{1-(0.990)^2} = \boxed{0.141c}$$

(*b*) We use Eq. 36-1a for time dilation with the time as measured from a relative moving frame 1.00% greater than the rest time.

$$\Delta t_0 = \Delta t\sqrt{1-v^2/c^2} \;\rightarrow\; v = c\sqrt{1-\left(\frac{\Delta t_0}{\Delta t}\right)^2} = c\sqrt{1-\left(\frac{1}{1.0100}\right)^2} = \boxed{0.140c}$$

We see that a speed of 0.14 *c* results in about a 1% relativistic effect.

12. (*a*) To an observer on Earth, 18.6 ly is the rest length, so the time will be the distance divided by the speed.

$$t_{\text{Earth}} = \frac{\ell_0}{v} = \frac{(18.6\text{ ly})}{0.950c} = 19.58\text{ yr} \approx \boxed{19.6\text{yr}}$$

(*b*) The time as observed on the spacecraft is shorter. Use Eq. 36-1a.

$$\Delta t_0 = \Delta t\sqrt{1-v^2/c^2} = (19.58\text{yr})\sqrt{1-(0.950)^2} = 6.114\text{ yr} \approx \boxed{6.11\text{yr}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) To the spacecraft observer, the distance to the star is contracted. Use Eq. 36-3a.

$$\ell = \ell_0\sqrt{1-v^2/c^2} = (18.6\text{ ly})\sqrt{1-(0.950)^2} = 5.808\text{ ly} \approx \boxed{5.81\text{ ly}}$$

(*d*) To the spacecraft observer, the speed of the spacecraft is their observed distance divided by their observed time.

$$v = \frac{\ell}{\Delta t_0} = \frac{(5.808\text{ ly})}{6.114\text{ yr}} = \boxed{0.950c}$$

13. (*a*) In the Earth frame, the clock on the *Enterprise* will run slower. Use Eq. 36-1a.

$$\Delta t_0 = \Delta t\sqrt{1-v^2/c^2} = (5.0\text{ yr})\sqrt{1-(0.74)^2} = \boxed{3.4\text{ yr}}$$

(*b*) Now we assume the 5.0 years is the time as measured on the *Enterprise*. Again use Eq. 36-1a.

$$\Delta t_0 = \Delta t\sqrt{1-v^2/c^2} \quad \rightarrow \quad \Delta t = \frac{\Delta t_0}{\sqrt{1-v^2/c^2}} = \frac{(5.0\text{ yr})}{\sqrt{1-(0.74)^2}} = \boxed{7.4\text{ yr}}$$

14. We find the speed of the particle in the lab frame, and use that to find the rest frame lifetime and distance.

$$v = \frac{\Delta x_{\text{lab}}}{\Delta t_{\text{lab}}} = \frac{1.00\text{ m}}{3.40\times10^{-9}\text{ s}} = 2.941\times10^8\text{ m/s} = 0.9803c$$

(*a*) Find the rest frame lifetime from Eq. 36-1a.

$$\Delta t_0 = \Delta t_{\text{lab}}\sqrt{1-v^2/c^2} = (3.40\times10^{-9}\text{ s})\sqrt{1-(0.9803)^2} = \boxed{6.72\times10^{-10}\text{ s}}$$

(*b*) In its rest frame, the particle will travel the distance given by its speed and the rest lifetime.

$$\Delta x_0 = v\Delta t_0 = (2.941\times10^8\text{ m/s})(6.72\times10^{-10}\text{ s}) = \boxed{0.198\text{ m}}$$

This could also be found from the length contraction relationship: $\Delta x_0 = \dfrac{\Delta x_{\text{lab}}}{\sqrt{1-v^2/c^2}}$.

15. Since the number of particles passing per second is reduced from *N* to *N* / 2, a time T_0 must have elapsed in the particles' rest frame. The time *T* elapsed in the lab frame will be greater, according to Eq. 36-1a. The particles moved a distance of $2cT_0$ in the lab frame during that time.

$$T_0 = T\sqrt{1-v^2/c^2} \quad \rightarrow \quad T = \frac{T_0}{\sqrt{1-v^2/c^2}} \;;\; v = \frac{x}{T} = \frac{2cT_0}{\dfrac{T_0}{\sqrt{1-v^2/c^2}}} \quad \rightarrow \quad v = \sqrt{\tfrac{4}{5}}c = \boxed{0.894c}$$

16. The dimension along the direction of motion is contracted, and the other two dimensions are unchanged. Use Eq. 36-3a to find the contracted length.

$$\ell = \ell_0\sqrt{1-v^2/c^2} \;;\; V = \ell(\ell_0)^2 = (\ell_0)^3\sqrt{1-v^2/c^2} = (2.0\text{ m})^3\sqrt{1-(0.80)^2} = \boxed{4.8\text{ m}^3}$$

17. The vertical dimensions of the ship will not change, but the horizontal dimensions will be contracted according to Eq. 36-3a. The base will be contracted as follows.

$$\ell_{\text{base}} = \ell\sqrt{1-v^2/c^2} = \ell\sqrt{1-(0.95)^2} = \boxed{0.31\ell}$$

When at rest, the angle of the sides with respect to the base is given by $\theta = \cos^{-1}\dfrac{0.50\ell}{2.0\ell} = 75.52°$.

The vertical component of $\ell_{\text{vert}} = 2\ell\sin\theta = 2\ell\sin 75.52° = 1.936\ell$ is unchanged. The horizontal

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

component, which is $2\ell\cos\theta = 2\ell\left(\frac{1}{4}\right) = 0.50\ell$ at rest, will be contracted in the same way as the base.

$$\ell_{\text{horizontal}} = 0.50\ell\sqrt{1-v^2/c^2} = 0.50\ell\sqrt{1-(0.95)^2} = 0.156\ell$$

Use the Pythagorean theorem to find the length of the leg.

$$\ell_{\text{leg}} = \sqrt{\ell_{\text{horizontal}}^2 + \ell_{\text{vert}}^2} = \sqrt{(0.156\ell)^2 + (1.936\ell)^2} = 1.942\ell \approx \boxed{1.94\ell}$$

18. In the Earth frame, the average lifetime of the pion will be dilated according to Eq. 36-1a. The speed of the pion will be the distance moved in the Earth frame times the dilated time.

$$v = \frac{d}{\Delta t} = \frac{d}{\Delta t_0}\sqrt{1-v^2/c^2} \quad \rightarrow$$

$$v = c\sqrt{\frac{1}{1+\left(\frac{c\Delta t_0}{d}\right)^2}} = c\sqrt{\frac{1}{1+\left(\frac{(3.00\times10^8\,\text{m/s})(2.6\times10^{-8}\,\text{s})}{(25\,\text{m})}\right)^2}} = \boxed{0.95c}$$

19. We take the positive direction in the direction of the *Enterprise*. Consider the alien vessel as reference frame S, and the Earth as reference frame S′. The velocity of the Earth relative to the alien vessel is $v = -0.60c$. The velocity of the *Enterprise* relative to the Earth is $u_x' = 0.90c$. Solve for the velocity of the *Enterprise* relative to the alien vessel, u_x, using Eq. 36-7a.

$$u_x = \frac{(u_x' + v)}{\left(1+\frac{vu_x'}{c^2}\right)} = \frac{(0.90c - 0.60c)}{\left[1+(-0.60)(0.90)\right]} = \boxed{0.65c}$$

We could also have made the *Enterprise* as reference frame S, with $v = -0.90c$, and the velocity of the alien vessel relative to the Earth as $u_x' = 0.60c$. The same answer would result.

Choosing the two spacecraft as the two reference frames would also work. Let the alien vessel be reference frame S, and the *Enterprise* be reference frame S′. Then we have the velocity of the Earth relative to the alien vessel as $u_x = -0.60c$, and the velocity of the Earth relative to the *Enterprise* as $u_x' = -0.90c$. We solve for *v*, the velocity of the *Enterprise* relative to the alien vessel.

$$u_x = \frac{(u_x' + v)}{\left(1+\frac{vu_x'}{c^2}\right)} \quad \rightarrow \quad v = \frac{u_x - u_x'}{\left(1-\frac{u_x'u_x}{c^2}\right)} = \frac{(-.60c)-(-0.90c)}{\left(1-\frac{(-0.90c)(-.60c)}{c^2}\right)} = \boxed{0.65c}$$

20. The Galilean transformation is given in Eq. 36-4.

(*a*) $(x, y, z) = (x' + vt', y', z') = (25\,\text{m} + (30\,\text{m/s})(3.5\,\text{s}), 20\,\text{m}, 0) = \boxed{(130\,\text{m}, 20\,\text{m}, 0)}$

(*b*) $(x, y, z) = (x' + vt', y', z') = (25\,\text{m} + (30\,\text{m/s})(10.0\,\text{s}), 20\,\text{m}, 0) = \boxed{(325\,\text{m}, 20\,\text{m}, 0)}$

21. (*a*) The person's coordinates in S are found using Eq. 36-6, with $x' = 25$ m, $y' = 20$ m, $z' = 0$, and $t' = 3.5\,\mu$s. We set $v = 1.80\times10^8$ m/s.

$$x = \frac{x' + vt'}{\sqrt{1-v^2/c^2}} = \frac{25\,\text{m} + (1.8\times10^8\,\text{m/s})(3.5\,\mu\text{s})}{\sqrt{1-(1.8\times10^8\,\text{m/s})^2/(3.0\times10^8\,\text{m/s})^2}} = \boxed{820\,\text{m}}$$

$$y = y' = \boxed{20\,\text{m}} \;;\; z = z' = \boxed{0}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We repeat part (*a*) using the time $t' = 10.0\,\mu\text{s}$.

$$x = \frac{x' + vt'}{\sqrt{1 - v^2/c^2}} = \frac{25\,\text{m} + \left(1.8\times10^8\,\text{m/s}\right)\left(10.0\,\mu\text{s}\right)}{\sqrt{1 - \left(1.8\times10^8\,\text{m/s}\right)^2 / \left(3.0\times10^8\,\text{m/s}\right)^2}} = \boxed{2280\,\text{m}}$$

$$y = y' = \boxed{20\,\text{m}} \;\; ; \;\; z = z' = \boxed{0}$$

22. We determine the components of her velocity in the S frame using Eq. 36-7, where $u'_x = u'_y = 1.10\times10^8\,\text{m/s}$ and $v = 1.80\times10^8\,\text{m/s}$. Then using trigonometry we combine the components to determine the magnitude and direction.

$$u_x = \frac{u'_x + v}{1 + vu'_x/c^2} = \frac{1.10\times10^8\,\text{m/s} + 1.80\times10^8\,\text{m/s}}{1 + \left(1.80\times10^8\,\text{m/s}\right)\left(1.10\times10^8\,\text{m/s}\right)/\left(3.00\times10^8\,\text{m/s}\right)^2} = 2.38\times10^8\,\text{m/s}$$

$$u_y = \frac{u'_y\sqrt{1 - v^2/c^2}}{1 + vu'_x/c^2} = \frac{\left(1.10\times10^8\,\text{m/s}\right)\sqrt{1 - \left(1.8\times10^8\,\text{m/s}\right)^2/\left(3.0\times10^8\,\text{m/s}\right)^2}}{1 + \left(1.80\times10^8\,\text{m/s}\right)\left(1.10\times10^8\,\text{m/s}\right)/\left(3.00\times10^8\,\text{m/s}\right)^2} = 7.21\times10^7\,\text{m/s}$$

$$u = \sqrt{u_x^2 + u_y^2} = \sqrt{\left(2.38\times10^8\,\text{m/s}\right)^2 + \left(7.21\times10^7\,\text{m/s}\right)^2} = \boxed{2.49\times10^8\,\text{m/s}}$$

$$\theta = \tan^{-1}\frac{u_y}{u_x} = \tan^{-1}\frac{7.21\times10^7\,\text{m/s}}{2.38\times10^8\,\text{m/s}} = \boxed{16.9^\circ}$$

23. (*a*) We take the positive direction to be the direction of motion of spaceship 1. Consider spaceship 2 as reference frame S, and the Earth reference frame S′. The velocity of the Earth relative to spaceship 2 is $v = 0.60c$. The velocity of spaceship 1 relative to the Earth is $u'_x = 0.60c$. Solve for the velocity of spaceship 1 relative to spaceship 2, u_x, using Eq. 36-7a.

$$u_x = \frac{\left(u'_x + v\right)}{\left(1 + \dfrac{vu'_x}{c^2}\right)} = \frac{\left(0.60c + 0.60c\right)}{\left[1 + \left(0.60\right)\left(0.60\right)\right]} = \boxed{0.88c}$$

(*b*) Now consider spaceship 1 as reference frame S. The velocity of the Earth relative to spaceship 1 is $v = -0.60c$. The velocity of spaceship 2 relative to the Earth is $u'_x = -0.60c$. Solve for the velocity of spaceship 2 relative to spaceship 1, u_x, using Eq. 36-7a.

$$u_x = \frac{\left(u'_x + v\right)}{\left(1 + \dfrac{vu'_x}{c^2}\right)} = \frac{\left(-0.60c - 0.60c\right)}{\left[1 + \left(-0.60\right)\left(-0.60\right)\right]} = \boxed{-0.88c}$$

As expected, the two relative velocities are the opposite of each other.

24. (*a*) The Galilean transformation is given in Eq. 36-4.

$$x = x' + vt' = x' + vt = 100\,\text{m} + \left(0.92\right)\left(3.00\times10^8\,\text{m/s}\right)\left(1.00\times10^{-6}\,\text{s}\right) = \boxed{376\,\text{m}}$$

(*b*) The Lorentz transformation is given in Eq. 36-6. Note that we are given *t*, the clock reading in frame S.

$$t = \gamma\left(t' + \frac{vx'}{c^2}\right) \;\; \rightarrow \;\; t' = \frac{t}{\gamma} - \frac{vx'}{c^2}$$

$$x = \gamma\left(x' + vt'\right) \;\; = \gamma\left[x' + v\left(\frac{t}{\gamma} - \frac{vx'}{c^2}\right)\right] = \gamma\left[x' + \frac{v}{c}\left(\frac{ct}{\gamma} - \frac{vx'}{c}\right)\right]$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \frac{1}{\sqrt{1-0.92^2}}\left[(100\,\text{m}) + (0.92)\left(\sqrt{1-0.92^2}\,(3.00\times10^8\,\text{m/s})(1.00\times10^{-6}\,\text{s}) - 0.92(100\,\text{m})\right)\right]$$
$$= \boxed{316\,\text{m}}$$

25. (*a*) We take the positive direction in the direction of the first spaceship. We choose reference frame S as the Earth, and reference frame S′ as the first spaceship. So $v = 0.61c$. The speed of the second spaceship relative to the first spaceship is $u'_x = 0.87c$. We use Eq. 36-7a to solve for the speed of the second spaceship relative to the Earth, *u*.

$$u_x = \frac{(u'_x + v)}{\left(1 + \frac{vu'_x}{c^2}\right)} = \frac{(0.87c + 0.61c)}{[1 + (0.61)(0.87)]} = \boxed{0.97c}$$

(*b*) The only difference is now that $u'_x = -0.87c$.

$$u_x = \frac{(u'_x + v)}{\left(1 + \frac{vu'_x}{c^2}\right)} = \frac{(-0.87c + 0.61c)}{[1 + (0.61)(-0.87)]} = -0.55c$$

The problem asks for the speed, which would be $\boxed{0.55c}$

26. We assume that the given speed of 0.90*c* is relative to the planet that you are approaching. We take the positive direction in the direction that you are traveling. Consider your spaceship as reference frame S, and the planet as reference frame S′. The velocity of the planet relative to you is $v = -0.90c$. The velocity of the probe relative to the planet is $u'_x = 0.95c$. Solve for the velocity of the probe relative to your spaceship, u_x, using Eq. 36-7a.

$$u_x = \frac{(u'_x + v)}{\left(1 + \frac{vu'_x}{c^2}\right)} = \frac{(0.95c - 0.90c)}{[1 + (-0.90)(0.95)]} = \boxed{0.34c}$$

27. We set frame S′ as the frame at rest with the spaceship. In this frame the module has speed $u' = u'_y = 0.82c$. Frame S is the frame that is stationary with respect to the Earth. The spaceship, and therefore frame S′ moves in the *x*-direction with speed 0.76c in this frame, or $v = 0.76c$. We use Eq. 36-7a and 36-7b to determine the components of the module velocity in frame S. Then using trigonometry we combine the components to determine the speed and direction of travel.

$$u_x = \frac{u'_x + v}{1 + vu'_x/c^2} = \frac{0 + 0.76c}{1 + 0} = 0.76c \;\; ; \;\; u_y = \frac{u'_y\sqrt{1 - v^2/c^2}}{1 + vu'_x/c^2} = \frac{0.82c\sqrt{1-0.76^2}}{1+0} = 0.533c$$

$$u = \sqrt{u_x^2 + u_y^2} = \sqrt{(0.76c)^2 + (0.533c)^2} = \boxed{0.93c} \;\; ; \;\; \theta = \tan^{-1}\frac{u_y}{u_x} = \tan^{-1}\frac{0.533c}{0.76c} = \boxed{35°}$$

28. The velocity components of the particle in the S frame are $u_x = u\cos\theta$ and $u_y = u\sin\theta$. We find the components of the particle in the S′ frame from the velocity transformations given in Eqs. 36-7a and 36-7b. Those transformations are for the S′ frame moving with speed *v* relative to the S frame. We can find the transformations from the S frame to the S′ frame by simply changing *v* to –*v* and primed to unprimed variables.

$$u_x = \frac{(u'_x + v)}{(1 + vu'_x/c^2)} \;\rightarrow\; u'_x = \frac{(u_x - v)}{(1 - vu_x/c^2)} \;\; ; \;\; u_y = \frac{u'_y\sqrt{1 - v^2/c^2}}{(1 + vu_x/c^2)} \;\rightarrow\; u'_y = \frac{u_y\sqrt{1 - v^2/c^2}}{(1 - vu_x/c^2)}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\tan\theta' = \frac{u'_y}{u'_x} = \frac{\dfrac{u_y\sqrt{1-v^2/c^2}}{\left(1-vu_x/c^2\right)}}{\dfrac{\left(u_x-v\right)}{\left(1-vu_x/c^2\right)}} = \frac{u_y\sqrt{1-v^2/c^2}}{\left(u_x-v\right)} = \frac{u\sin\theta\sqrt{1-v^2/c^2}}{\left(u\cos\theta-v\right)} = \boxed{\frac{\sin\theta\sqrt{1-v^2/c^2}}{\left(\cos\theta-v/u\right)}}$$

29. (*a*) In frame S′ the horizontal component of the stick length will be contracted, while the vertical component remains the same. We use the trigonometric relations to determine the *x*- and *y*-components of the length of the stick. Then using Eq. 36-3a we determine the contracted length of the *x*-component. Finally, we use the Pythagorean theorem to determine stick length in frame S′.

$$\ell_x = \ell_0\cos\theta \;;\; \ell_y = \ell_0\sin\theta = \ell'_y \;;\; \ell'_x = \ell_x\sqrt{1-v^2/c^2} = \ell_0\cos\theta\sqrt{1-v^2/c^2}$$

$$\ell = \sqrt{\ell'^2_x + \ell'^2_y} = \sqrt{\ell_0{}^2\cos^2\theta\left(1-v^2/c^2\right) + \ell_0{}^2\sin^2\theta} = \boxed{\ell_0\sqrt{1-\left(v\cos\theta/c\right)^2}}$$

(*b*) We calculate the angle from the length components in the moving frame.

$$\theta' = \tan^{-1}\frac{\ell'_y}{\ell'_x} = \tan^{-1}\left(\frac{\ell_0\sin\theta}{\ell_0\cos\theta\sqrt{1-v^2/c^2}}\right) = \tan^{-1}\left(\frac{\tan\theta}{\sqrt{1-v^2/c^2}}\right) = \boxed{\tan^{-1}\left(\gamma\tan\theta\right)}$$

30. (*a*) We choose the train as frame S′ and the Earth as frame S. Since the guns fire simultaneously in S′ , we set these times equal to zero, that is $t'_A = t'_B = 0$. To simplify the problem we also set the location of gunman A equal to zero in frame S′ when the guns were fired, $x'_A = 0$. This places gunman B at $x'_B = 55.0\,\text{m}$. Use Eq. 36-6 to determine the time that each gunman fired his weapon in frame S.

$$t_A = \gamma\left(t'_A + \frac{vx'_A}{c^2}\right) = \gamma\left(0 + \frac{v\times 0}{c^2}\right) = 0$$

$$t_B = \gamma\left(t'_B + \frac{vx'_B}{c^2}\right) = \frac{1}{\sqrt{1-\left(35.0\,\text{m/s}/3.00\times10^8\,\text{m/s}\right)^2}}\left(0 + \frac{(35\,\text{m/s})(55.0\,\text{m})}{\left(3.00\times10^8\,\text{m/s}\right)^2}\right) = 2.14\times10^{-14}\,\text{s}$$

Therefore, in Frame S, A fired first.

(*b*) As found in part (*a*), the difference in time is $\boxed{2.14\times10^{-14}\,\text{s}}$.

(*c*) In the Earth frame of reference, since A fired first, B was struck first. In the train frame, A is moving away from the bullet fired toward him, and B is moving toward the bullet fired toward him. Thus B will be struck first in this frame as well.

31. We set frame S′ as the frame moving with the observer. Frame S is the frame in which the two light bulbs are at rest. Frame S is moving with velocity *v* with respect to frame S′. We solve Eq. 36-6 for the time t' in terms of *t*, *x*, and *v*. Using the resulting equation we determine the time in frame S′ that each bulb is turned on, given that in frame S the bulbs are turned on simultaneously at $t_A = t_B = 0$. Taking the difference in these times gives the time interval as measured by the observing moving with velocity *v*.

$$x = \gamma\left(x' + vt'\right) \rightarrow x' = \frac{x}{\gamma} - vt'$$

$$t = \gamma\left(t' + \frac{vx'}{c^2}\right) = \gamma\left[t' + \frac{v}{c^2}\left(\frac{x}{\gamma} - vt'\right)\right] = \gamma t'\left(1-\frac{v^2}{c^2}\right) + \frac{vx}{c^2} = \frac{t'}{\gamma} + \frac{vx}{c^2} \;\rightarrow\; t' = \gamma\left(t - \frac{vx}{c^2}\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$t'_A = \gamma\left(t_A - \frac{vx_A}{c^2}\right) = \gamma\left(0 - \frac{v\times 0}{c^2}\right) = 0 \;\; ; \;\; t'_B = \gamma\left(t_B - \frac{vx_B}{c^2}\right) = \gamma\left(0 - \frac{v\ell}{c^2}\right) = -\gamma\frac{v\ell}{c^2}$$

$$\Delta t' = t'_B - t'_A = \boxed{-\gamma\frac{v\ell}{c^2}}$$

According to the observer, bulb B turned on first.

32. We set up the two frames such that in frame S, the first object is located at the origin and the second object is located 220 meters from the origin, so $x_A = 0$ and $x_B = 220$ m. We set the time when event A occurred equal to zero, so $t_A = 0$ and $t_B = 0.80\,\mu$s. We then set the location of the two events in frame S′ equal, and using Eq. 36-6 we solve for the velocity.

$$x'_A = x'_B \;\; \rightarrow \;\; \gamma\left(x_A - vt_A\right) = \gamma\left(x_B - vt_B\right) \;\; ; \;\; v = \frac{x_A - x_B}{t_A - t_B} = \frac{0 - 220\,\text{m}}{0 - 0.88\;\mu\text{s}} = \boxed{2.5\times 10^8\,\text{m/s}}$$

33. From the boy's frame of reference, the pole remains at rest with respect to him. As such, the pole will always remain 12.0 m long. As the boy runs toward the barn, relativity requires that the (relatively moving) barn contract in size, making the barn even shorter than its rest length of 10.0 m. Thus it is impossible, in the boy's frame of reference, for the barn to be longer than the pole. So according to the boy, the pole will never completely fit within the barn.

In the frame of reference at rest with respect to the barn, it is possible for the pole to be shorter than the barn. We use Eq. 36-3a to calculate the speed that the boy would have to run for the contracted length of the pole, ℓ, to equal the length of the barn.

$$\ell = \ell_0\sqrt{1 - v^2/c^2} \;\; \rightarrow \;\; v = c\sqrt{1 - \ell^2/\ell_0^2} = c\sqrt{1 - (10.0\text{ m})^2/(12.0\text{ m})^2} = 0.5528c$$

If persons standing at the front and back door of the barn were to close both doors exactly when the pole was completely inside the barn, we would have two simultaneous events in the barn's rest frame S with the pole completely inside the barn. Let us set the time for these two events as $t_A = t_B = 0$. In frame S these two events occur at the front and far side of the barn, or at $x_A = 0$ and $x_B = 10.0$ m. Using Eq. 36-6, we calculate the times at which the barn doors close in the boy's frame of reference.

$$t'_A = \gamma\left(t_A - \frac{vx_A}{c^2}\right) = \gamma\left(0 - \frac{v\times 0}{c^2}\right) = 0$$

$$t'_B = \gamma\left(t_B - \frac{vx_B}{c^2}\right) = \frac{1}{\sqrt{1 - 0.5528^2}}\left[0 - \frac{0.5528(10.0\,\text{m})}{3.00\times 10^8\,\text{m/s}}\right] = -2.211\times 10^{-8}\,\text{s}$$

Therefore, in the boy's frame of reference the far door of the barn closed 22.1 ns before the front door. If we multiply the speed of the boy by this time difference, we calculate the distance the boy traveled between the closing of the two doors.

$$\Delta x = vt = 0.5528\left(3.00\times 10^8\text{ m/s}\right)\left(2.211\times 10^{-8}\text{ s}\right) = 3.67\text{ m}.$$

We use Eq. 36-3a to determine the length of the barn in the boy's frame of reference.

$$\ell = \ell_0\sqrt{1 - v^2/c^2} = (10.0\text{ m})\sqrt{1 - 0.5528^2} = 8.33\text{ m}$$

Subtracting the distance traveled between closing the doors from the length of the pole, we find the length of the barn in the boy's frame of reference.

$$\ell_{0,\text{pole}} - \Delta x = 12.0\text{ m} - 3.67\text{ m} = 8.33\text{ m} = \ell_{\text{barn}}$$

Therefore, in the boy's frame of reference, when the front of the pole reached the far door it was closed. Then 22.1 ns later, when the back of the pole reached the front door, that door was closed. In the boy's frame of reference these two events are not simultaneous.

34. The momentum of the proton is given by Eq. 36-8.

$$p = \gamma mv = \frac{mv}{\sqrt{1 - v^2/c^2}} = \frac{\left(1.67 \times 10^{-27}\ \text{kg}\right)\left(0.75\right)\left(3.00 \times 10^{8}\ \text{m/s}\right)}{\sqrt{1 - \left(0.75\right)^2}} = \boxed{5.7 \times 10^{-19}\ \text{kg}\cdot\text{m/s}}$$

35. (*a*) We compare the classical momentum to the relativistic momentum.

$$\frac{p_{\text{classical}}}{p_{\text{relativistic}}} = \frac{mv}{\dfrac{mv}{\sqrt{1 - v^2/c^2}}} = \sqrt{1 - v^2/c^2} = \sqrt{1 - \left(0.10\right)^2} = 0.995$$

The classical momentum is about $\boxed{-0.5\%}$ in error.

(*b*) We again compare the two momenta.

$$\frac{p_{\text{classical}}}{p_{\text{relativistic}}} = \frac{mv}{\dfrac{mv}{\sqrt{1 - v^2/c^2}}} = \sqrt{1 - v^2/c^2} = \sqrt{1 - \left(0.60\right)^2} = 0.8$$

The classical momentum is $\boxed{-20\%}$ in error.

36. The momentum at the higher speed is to be twice the initial momentum. We designate the initial state with a subscript "0", and the final state with a subscript "f".

$$\frac{p_{\text{f}}}{p_0} = \frac{\dfrac{mv_{\text{f}}}{\sqrt{1 - v_{\text{f}}^2/c^2}}}{\dfrac{mv_0}{\sqrt{1 - v_0^2/c^2}}} = 2 \quad \rightarrow \quad \frac{\dfrac{v_{\text{f}}^2}{1 - v_{\text{f}}^2/c^2}}{\dfrac{v_0^2}{1 - v_0^2/c^2}} = 4 \quad \rightarrow \quad \left(\frac{v_{\text{f}}^2}{1 - v_{\text{f}}^2/c^2}\right) = 4\left[\frac{\left(0.26c\right)^2}{1 - \left(0.26\right)^2}\right] = 0.29c^2 \quad \rightarrow$$

$$v_{\text{f}}^2 = \left(\frac{0.29}{1.29}\right)c^2 \quad \rightarrow \quad v_{\text{f}} = \boxed{0.47c}$$

37. The two momenta, as measured in the frame in which the particle was initially at rest, will be equal to each other in magnitude. The lighter particle is designated with a subscript "1", and the heavier particle with a subscript "2".

$$p_1 = p_2 \quad \rightarrow \quad \frac{m_1 v_1}{\sqrt{1 - v_1^2/c^2}} = \frac{m_2 v_2}{\sqrt{1 - v_2^2/c^2}} \quad \rightarrow$$

$$\frac{v_1^2}{\left(1 - v_1^2/c^2\right)} = \left(\frac{m_2}{m_1}\right)^2 \frac{v_2^2}{\left(1 - v_2^2/c^2\right)} = \left(\frac{6.68 \times 10^{-27}\ \text{kg}}{1.67 \times 10^{-27}\ \text{kg}}\right)^2 \left[\frac{\left(0.60c\right)^2}{1 - \left(0.60\right)^2}\right] = 9.0c^2 \quad \rightarrow$$

$$v_1 = \sqrt{0.90}\,c = \boxed{0.95c}$$

38. We find the proton's momenta using Eq. 36-8.

$$p_{0.45} = \frac{m_{\text{p}} v_1}{\sqrt{1 - \dfrac{v_1^2}{c^2}}} = \frac{m_{\text{p}}\left(0.45c\right)}{\sqrt{1 - \left(0.45\right)^2}} = 0.5039 m_{\text{p}} c \ ; \ p_{0.80} = \frac{m_{\text{p}} v_2}{\sqrt{1 - \dfrac{v_2^2}{c^2}}} = \frac{m_{\text{p}}\left(0.80c\right)}{\sqrt{1 - \left(0.80\right)^2}} = 1.3333 m_{\text{p}} c$$

$$p_{0.98} = \frac{m_{\text{p}} v_2}{\sqrt{1 - \dfrac{v_2^2}{c^2}}} = \frac{m_{\text{p}}\left(0.98c\right)}{\sqrt{1 - \left(0.98\right)^2}} = 4.9247 m_{\text{p}} c$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*a*) $\left(\frac{p_2 - p_1}{p_1}\right)100 = \left(\frac{1.3333m_p c - 0.5039m_p c}{0.5039m_p c}\right)100 = 164.6 \approx \boxed{160\%}$

(*b*) $\left(\frac{p_2 - p_1}{p_1}\right)100 = \left(\frac{4.9247m_p c - 1.3333m_p c}{1.3333m_p c}\right)100 = 269.4 \approx \boxed{270\%}$

39. The rest energy of the electron is given by Eq. 36-12.

$$E = mc^2 = \left(9.11\times10^{-31}\,\text{kg}\right)\left(3.00\times10^8\,\text{m/s}\right)^2 = \boxed{8.20\times10^{-14}\,\text{J}}$$

$$= \frac{\left(8.20\times10^{-14}\,\text{J}\right)}{\left(1.60\times10^{-13}\,\text{J/MeV}\right)} = \boxed{0.511\,\text{MeV}}$$

40. We find the loss in mass from Eq. 36-12.

$$m = \frac{E}{c^2} = \frac{\left(200\,\text{MeV}\right)\left(1.60\times10^{-13}\,\text{J/MeV}\right)}{\left(3.00\times10^8\,\text{m/s}\right)^2} = 3.56\times10^{-28}\,\text{kg} \approx \boxed{4\times10^{-28}\,\text{kg}}$$

41. We find the mass conversion from Eq. 36-12.

$$m = \frac{E}{c^2} = \frac{\left(8\times10^{19}\,\text{J}\right)}{\left(3.00\times10^8\,\text{m/s}\right)^2} = \boxed{900\,\text{kg}}$$

42. We calculate the mass from Eq. 36-12.

$$m = \frac{E}{c^2} = \frac{1}{c^2}\left(mc^2\right) = \frac{1}{c^2}\frac{\left(1.6726\times10^{-27}\,\text{kg}\right)\left(2.9979\times10^8\,\text{m/s}\right)^2}{\left(1.6022\times10^{-13}\,\text{J/MeV}\right)} = \boxed{938.2\,\text{MeV}/c^2}$$

43. Each photon has momentum 0.50 MeV/*c*. Thus each photon has mass 0.50 MeV. Assuming the photons have opposite initial directions, then the total momentum is 0, and so the product mass will not be moving. Thus all of the photon energy can be converted into the mass of the particle. Accordingly, the heaviest particle would have a mass of $\boxed{1.00\,\text{MeV}/c^2}$, which is 1.78×10^{-30} kg. .

44. (*a*) The work is the change in kinetic energy. Use Eq. 36-10b. The initial kinetic energy is 0.

$$W = \Delta K = K_{\text{final}} = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1-0.998^2}} - 1\right)\left(938.3\,\text{MeV}\right) = 1.39\times10^4\,\text{MeV}$$

$$= \boxed{13.9\,\text{GeV}}$$

(*b*) The momentum of the proton is given by Eq. 36-8.

$$p = \gamma mv = \frac{1}{\sqrt{1-0.998^2}}\left(938.3\,\text{MeV}/c^2\right)\left(0.998c\right) = 1.48\times10^4\ \text{MeV}/c = \boxed{14.8\,\text{GeV}/c}$$

45. We find the energy equivalent of the mass from Eq. 36-12.

$$E = mc^2 = \left(1.0\times10^{-3}\,\text{kg}\right)\left(3.00\times10^8\,\text{m/s}\right)^2 = \boxed{9.0\times10^{13}\,\text{J}}$$

We assume that this energy is used to increase the gravitational potential energy.

$$E = mgh \;\rightarrow\; m = \frac{E}{hg} = \frac{9.0\times10^{13}\,\text{J}}{\left(1.0\times10^3\,\text{m}\right)\left(9.80\,\text{m/s}^2\right)} = \boxed{9.2\times10^9\,\text{kg}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

46. The work is the change in kinetic energy. Use Eq. 36-10b. The initial kinetic energy is 0.

$$W_1 = (\gamma_{0.90} - 1)mc^2 \;\; ; \;\; W_2 = K_{0.99c} - K_{0.90c} = (\gamma_{0.99} - 1)mc^2 - (\gamma_{0.90} - 1)mc^2$$

$$\frac{W_2}{W_1} = \frac{(\gamma_{0.99} - 1)mc^2 - (\gamma_{0.90} - 1)mc^2}{(\gamma_{0.90} - 1)mc^2} = \frac{\gamma_{0.99} - \gamma_{0.90}}{\gamma_{0.90} - 1} = \frac{\dfrac{1}{\sqrt{1 - 0.99^2}} - \dfrac{1}{\sqrt{1 - 0.90^2}}}{\dfrac{1}{\sqrt{1 - 0.90^2}} - 1} = \boxed{3.7}$$

47. The kinetic energy is given by Eq. 36-10.

$$K = (\gamma - 1)mc^2 = mc^2 \;\; \rightarrow \;\; \gamma = 2 = \frac{1}{\sqrt{1 - v^2/c^2}} \;\; \rightarrow \;\; v = \sqrt{\frac{3}{4}}c = \boxed{0.866c}$$

48. The total energy of the proton is the kinetic energy plus the mass energy. Use Eq. 36-13 to find the momentum.

$$E = K + mc^2 \;\; ;$$

$$(pc)^2 = E^2 - (mc^2)^2 = (K + mc^2)^2 - (mc^2)^2 = K^2 + 2K(mc^2)$$

$$pc = \sqrt{K^2 + 2K(mc^2)} = K\sqrt{1 + 2\frac{mc^2}{K}} = (950\,\text{MeV})\sqrt{1 + 2\frac{938.3\,\text{MeV}}{950\,\text{MeV}}} = 1638\,\text{MeV}$$

$$p = 1638\,\text{MeV}/c \approx \boxed{1.6\,\text{GeV}/c}$$

49. We find the speed in terms of c. The kinetic energy is given by Eq. 36-10 and the momentum by Eq. 36-8.

$$v = \frac{(2.80 \times 10^8\,\text{m/s})}{(3.00 \times 10^8\,\text{m/s})} = 0.9333c$$

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - 0.9333^2}} - 1\right)(938.3\,\text{MeV}) = 1674.6\,\text{MeV} \approx \boxed{1.67\,\text{GeV}}$$

$$p = \gamma mv = \frac{1}{\sqrt{1 - 0.9333^2}}(938.3\,\text{MeV}/c^2)(0.9333c) = 2439\,\text{MeV}/c \approx \boxed{2.44\,\text{GeV}/c}$$

50. We use Eq. 36-10 to find the speed from the kinetic energy.

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2 \;\; \rightarrow$$

$$v = c\sqrt{1 - \frac{1}{\left(\dfrac{K}{mc^2} + 1\right)^2}} = c\sqrt{1 - \frac{1}{\left(\dfrac{1.25\,\text{MeV}}{0.511\,\text{MeV}} + 1\right)^2}} = \boxed{0.957c}$$

51. Since the proton was accelerated by a potential difference of 125 MV, its potential energy decreased by 125 MeV, and so its kinetic energy increased from 0 to 125 MeV. Use Eq. 36-10 to find the speed from the kinetic energy.

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2 \;\; \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$v = c\sqrt{1-\frac{1}{\left(\frac{K}{mc^2}+1\right)^2}} = c\sqrt{1-\frac{1}{\left(\frac{125\,\text{MeV}}{938.3\,\text{MeV}}+1\right)^2}} = \boxed{0.470c}$$

52. We let M represent the rest mass of the new particle. The initial energy is due to both incoming particles, and the final energy is the rest energy of the new particle. Use Eq. 36-11 for the initial energies.

$$E = 2\left(\gamma mc^2\right) = Mc^2 \quad \rightarrow \quad M = 2\gamma m = \boxed{\frac{2m}{\sqrt{1-v^2/c^2}}}$$

We assumed that energy is conserved, and so there was no loss of energy in the collision. The final kinetic energy is 0, so all of the kinetic energy was lost.

$$K_{\text{lost}} = K_{\text{initial}} = 2(\gamma-1)mc^2 = \boxed{\left(\frac{1}{\sqrt{1-v^2/c^2}}-1\right)2mc^2}$$

53. Since the electron was accelerated by a potential difference of 28 kV, its potential energy decreased by 28 keV, and so its kinetic energy increased from 0 to 28 MeV. Use Eq. 36-10 to find the speed from the kinetic energy.

$$K = (\gamma-1)mc^2 = \left(\frac{1}{\sqrt{1-v^2/c^2}}-1\right)mc^2 \quad \rightarrow$$

$$v = c\sqrt{1-\frac{1}{\left(\frac{K}{mc^2}+1\right)^2}} = c\sqrt{1-\frac{1}{\left(\frac{0.028\,\text{MeV}}{0.511\,\text{MeV}}+1\right)^2}} = \boxed{0.32c}$$

54. We use Eqs. 36-11 and 36-13 in order to find the mass.

$$E^2 = p^2c^2 + m^2c^4 = \left(K+mc^2\right)^2 = K^2 + 2Kmc^2 + m^2c^4 \quad \rightarrow$$

$$m = \frac{p^2c^2 - K^2}{2Kc^2} = \frac{\left(121\,\text{MeV}/c\right)^2c^2 - \left(45\,\text{MeV}\right)^2}{2\left(45\,\text{MeV}\right)c^2} = \boxed{140\,\text{MeV}/c^2} \approx 2.5\times10^{-28}\,\text{kg}$$

The particle is most likely a probably a π^0 meson.

55. (*a*) Since the kinetic energy is half the total energy, and the total energy is the kinetic energy plus the rest energy, the kinetic energy must be equal to the rest energy. We also use Eq. 36-10.

$$K = \tfrac{1}{2}E = \tfrac{1}{2}\left(K+mc^2\right) \quad \rightarrow \quad K = mc^2$$

$$K = (\gamma-1)mc^2 = mc^2 \quad \rightarrow \quad \gamma = 2 = \frac{1}{\sqrt{1-v^2/c^2}} \quad \rightarrow \quad v = \sqrt{\tfrac{3}{4}}c = \boxed{0.866c}$$

(*b*) In this case, the kinetic energy is half the rest energy.

$$K = (\gamma-1)mc^2 = \tfrac{1}{2}mc^2 \quad \rightarrow \quad \gamma = \tfrac{3}{2} = \frac{1}{\sqrt{1-v^2/c^2}} \quad \rightarrow \quad v = \sqrt{\tfrac{5}{9}}c = \boxed{0.745c}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

56. We use Eq. 36-10 for the kinetic energy and Eq. 36-8 for the momentum.

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2 = \left(\frac{1}{\sqrt{1 - \left(\dfrac{8.15\times10^7\ \text{m/s}}{3.00\times10^8\ \text{m/s}}\right)^2}} - 1\right)(938.3\,\text{MeV})$$

$$= \boxed{36.7\,\text{MeV}}$$

$$p = \gamma mv = \frac{mv}{\sqrt{1 - v^2/c^2}} = \frac{1}{c}\frac{mc^2(v/c)}{\sqrt{1 - v^2/c^2}} = \frac{1}{c}\frac{(938.3\,\text{MeV})\left(\dfrac{8.15\times10^7\ \text{m/s}}{3.00\times10^8\ \text{m/s}}\right)}{\sqrt{1 - \left(\dfrac{8.15\times10^7\ \text{m/s}}{3.00\times10^8\ \text{m/s}}\right)^2}} = \boxed{265\,\text{MeV}/c}$$

Evaluate with the classical expressions.

$$K_c = \tfrac{1}{2}mv^2 = \tfrac{1}{2}mc^2\left(\frac{v}{c}\right)^2 = \tfrac{1}{2}(938.3\,\text{MeV})\left(\frac{8.15\times10^7\ \text{m/s}}{3.00\times10^8\ \text{m/s}}\right)^2 = 34.6\,\text{MeV}$$

$$p_c = mv = \frac{1}{c}mc^2\left(\frac{v}{c}\right) = (938.3\,\text{MeV})\left(\frac{8.15\times10^7\ \text{m/s}}{3.00\times10^8\ \text{m/s}}\right) = 255\,\text{MeV}/c$$

Calculate the percent error.

$$\text{error}_K = \frac{K_c - K}{K}\times100 = \frac{34.6 - 36.7}{36.7}\times100 = \boxed{-5.7\%}$$

$$\text{error}_p = \frac{p_c - p}{p}\times100 = \frac{255 - 265}{265}\times100 = \boxed{-3.8\%}$$

57. (*a*) The kinetic energy is found from Eq. 36-10.

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2 = \left(\frac{1}{\sqrt{1 - 0.18^2}} - 1\right)(1.7\times10^4\,\text{kg})(3.00\times10^8\ \text{m/s})^2$$

$$= 2.541\times10^{19}\,\text{J} \approx \boxed{2.5\times10^{19}\,\text{J}}$$

(*b*) Use the classical expression and compare the two results.

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(1.7\times10^4\,\text{kg})\left[(0.18)(3.00\times10^8\ \text{m/s})\right]^2 = 2.479\times10^{19}\,\text{J}$$

$$\%\,\text{error} = \frac{(2.479\times10^{19}\,\text{J}) - (2.541\times10^{19}\,\text{J})}{(2.541\times10^{19}\,\text{J})}\times100 = \boxed{-2.4\%}$$

The classical value is 2.4% too low.

58. The kinetic energy of 998 GeV is used to find the speed of the protons. Since the energy is 1000 times the rest mass, we expect the speed to be very close to *c*. Use Eq. 36-10.

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2 \quad \rightarrow$$

$$v = c\sqrt{1 - \frac{1}{\left(\dfrac{K}{mc^2} + 1\right)^2}} = c\sqrt{1 - \frac{1}{\left(\dfrac{998\,\text{GeV}}{0.938\,\text{GeV}} + 1\right)^2}} = c\,(\text{to 7 sig. fig.})$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$B = \frac{\gamma m v^2}{rqv} = \frac{\gamma m v}{rq} \approx \frac{\left(\frac{K}{mc^2} - 1\right)mc}{rq} = \frac{\left(\frac{998\,\text{GeV}}{0.938\,\text{GeV}} - 1\right)\left(1.673\times10^{-27}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.0\times10^{3}\,\text{m}\right)\left(1.60\times10^{-19}\,\text{C}\right)} = \boxed{3.3\,\text{T}}$$

59. By conservation of energy, the rest energy of the americium nucleus is equal to the rest energies of the other particles plus the kinetic energy of the alpha particle.

$$m_{\text{Am}}c^2 = \left(m_{\text{Np}} + m_\alpha\right)c^2 + K_\alpha \quad \rightarrow$$

$$m_{\text{Np}} = m_{\text{Am}} - m_\alpha - \frac{K_\alpha}{c^2} = 241.05682\,\text{u} - 4.00260\,\text{u} - \frac{5.5\,\text{MeV}}{c^2}\left(\frac{1\,\text{u}}{931.49\,\text{MeV}/c^2}\right) = \boxed{237.04832\,\text{u}}$$

60. (*a*) For a particle of non-zero mass, we derive the following relationship between kinetic energy and momentum.

$$E = K + mc^2 \;\; ; \;\; (pc)^2 = E^2 - \left(mc^2\right)^2 = \left(K + mc^2\right)^2 - \left(mc^2\right)^2 = K^2 + 2K\left(mc^2\right)$$

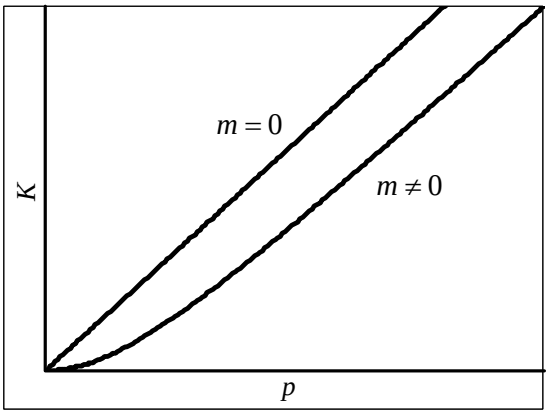
$$K^2 + 2K\left(mc^2\right) - (pc)^2 = 0 \;\; \rightarrow \;\; K = \frac{-2mc^2 \pm \sqrt{4\left(mc^2\right)^2 + 4(pc)^2}}{2}$$

For the kinetic energy to be positive, we take the positive root.

$$K = \frac{-2mc^2 + \sqrt{4\left(mc^2\right)^2 + 4(pc)^2}}{2} = -mc^2 + \sqrt{\left(mc^2\right)^2 + (pc)^2}$$

If the momentum is large, we have the following relationship.

$$K = -mc^2 + \sqrt{\left(mc^2\right)^2 + (pc)^2} \approx pc - mc^2$$



Thus there should be a linear relationship between kinetic energy and momentum for large values of momentum.

If the momentum is small, we use the binomial expansion to derive the classical relationship.

$$K = -mc^2 + \sqrt{\left(mc^2\right)^2 + (pc)^2} = -mc^2 + mc^2\sqrt{1 + \left(\frac{pc}{mc^2}\right)^2}$$

$$\approx -mc^2 + mc^2\left(1 + \tfrac{1}{2}\left(\frac{pc}{mc^2}\right)^2\right) = \frac{p^2}{2m}$$

Thus we expect a quadratic relationship for small values of momentum. The adjacent graph verifies these approximations.

(*b*) For a particle of zero mass, the relationship is simply $K = pc$. See the included graph. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH36.XLS," on tab "Problem 36.60."

61. All of the energy, both rest energy and kinetic energy, becomes electromagnetic energy. We use Eq. 36-11. Both masses are the same.

$$E_{\text{total}} = E_1 + E_2 = \gamma_1 mc^2 + \gamma_2 mc^2 = (\gamma_1 + \gamma_2)mc^2 = \left(\frac{1}{\sqrt{1-0.43^2}} + \frac{1}{\sqrt{1-0.55^2}}\right)(105.7\,\text{MeV})$$

$$= 243.6\,\text{MeV} \approx \boxed{240\,\text{MeV}}$$

62. We use Eqs. 36-11 and 36-13.

$$E = K + mc^2 \;\; ; \;\; (pc)^2 = E^2 - \left(mc^2\right)^2 = \left(K + mc^2\right)^2 - \left(mc^2\right)^2 = K^2 + 2K\left(mc^2\right) \;\; \rightarrow$$

$$\boxed{p = \frac{\sqrt{K^2 + 2K\left(mc^2\right)}}{c}}$$

63. (*a*) We assume the mass of the particle is *m*, and we are given that the velocity only has an *x*-component, u_x. We write the momentum in each frame using Eq. 36-8, and we use the velocity transformation given in Eq. 36-7. Note that there are three relevant velocities: u_x, the velocity in reference frame S; u'_x, the velocity in reference frame S′; and *v*, the velocity of one frame relative to the other frame. There is no velocity in the *y* or *z* directions, in either frame. We reserve the symbol γ for $\frac{1}{\sqrt{1-v^2/c^2}}$, and also use Eq. 36-11 for energy.

$$p_x = \frac{mu_x}{\sqrt{1-u_x^2/c^2}} \;\; ; \;\; p_y = 0 \;\; ; \;\; p_z = 0$$

$$u_x = \frac{u'_x + v}{1 + vu'_x/c^2} \;\; \rightarrow \;\; u'_x = \frac{u_x - v}{1 - vu_x/c^2} \;\; ; \;\; u'_y = u_y \frac{1 + vu'_x/c^2}{\sqrt{1-v^2/c^2}} = 0 \;\; ; \;\; u'_z = u_z \frac{1 + vu'_x/c^2}{\sqrt{1-v^2/c^2}} = 0$$

$$p'_x = \frac{mu'_x}{\sqrt{1-u'^2_x/c^2}} \;\; ; \;\; p'_y = 0\left(\text{since } u'_y = 0\right) \;\; ; \;\; p'_z = 0\left(\text{since } u'_z = 0\right)$$

Substitute the expression for u'_x into the expression for p'_x.

$$p'_x = \frac{mu'_x}{\sqrt{1-u'^2_x/c^2}} = \frac{m\dfrac{(u_x - v)}{\left(1 - vu_x/c^2\right)}}{\sqrt{1 - \dfrac{1}{c^2}\dfrac{(u_x - v)^2}{\left(1 - vu_x/c^2\right)^2}}} = m\frac{(u_x - v)}{\left(1 - vu_x/c^2\right)} \frac{1}{\sqrt{\dfrac{\left(1 - vu_x/c^2\right)^2}{\left(1 - vu_x/c^2\right)^2} - \dfrac{\dfrac{(u_x - v)^2}{c^2}}{\left(1 - vu_x/c^2\right)^2}}}$$

$$= m\frac{(u_x - v)}{\left(1 - vu_x/c^2\right)} \frac{1}{\dfrac{1}{\left(1 - vu_x/c^2\right)}\sqrt{\left(1 - vu_x/c^2\right)^2 - \dfrac{(u_x - v)^2}{c^2}}} = \frac{m(u_x - v)}{\sqrt{\left(1 - vu_x/c^2\right)^2 - \dfrac{(u_x - v)^2}{c^2}}}$$

$$= \frac{m(u_x - v)}{\sqrt{1 - 2\dfrac{vu_x}{c^2} + \left(\dfrac{vu_x}{c^2}\right)^2 - \dfrac{u_x^2}{c^2} + \dfrac{2u_x v}{c^2} - \dfrac{v^2}{c^2}}} = \frac{m(u_x - v)}{\sqrt{1 + \left(\dfrac{vu_x}{c^2}\right)^2 - \dfrac{u_x^2}{c^2} - \dfrac{v^2}{c^2}}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \frac{m(u_x - v)}{\sqrt{\left(1 - v^2/c^2\right)\left(1 - u_x^2/c^2\right)}} = \frac{\dfrac{mu_x}{\sqrt{\left(1 - u_x^2/c^2\right)}} - \dfrac{mv}{\sqrt{\left(1 - u_x^2/c^2\right)}}}{\sqrt{\left(1 - v^2/c^2\right)}}$$

$$= \frac{\dfrac{mu_x}{\sqrt{\left(1 - u_x^2/c^2\right)}} - \dfrac{mc^2}{\sqrt{\left(1 - u_x^2/c^2\right)}}\dfrac{v}{c^2}}{\sqrt{\left(1 - v^2/c^2\right)}} = \frac{p_x - \dfrac{mc^2}{\sqrt{\left(1 - u_x^2/c^2\right)}}\dfrac{v}{c^2}}{\sqrt{\left(1 - v^2/c^2\right)}} = \boxed{\frac{p_x - vE/c^2}{\sqrt{\left(1 - v^2/c^2\right)}}}$$

It is obvious from the first few equations of the problem that $\boxed{p'_y = p_y}(=0)$ and $\boxed{p'_z = p_z}(=0)$.

$$E' = \frac{mc^2}{\sqrt{1 - u'^2_x/c^2}} = \frac{mc^2}{\sqrt{1 - \dfrac{1}{c^2}\dfrac{(u_x - v)^2}{\left(1 - vu_x/c^2\right)^2}}} = \frac{mc^2}{\sqrt{\dfrac{\left(1 - vu_x/c^2\right)^2}{\left(1 - vu_x/c^2\right)^2} - \dfrac{\dfrac{(u_x - v)^2}{c^2}}{\left(1 - vu_x/c^2\right)^2}}}$$

$$= \frac{mc^2\left(1 - vu_x/c^2\right)}{\sqrt{\left(1 - vu_x/c^2\right)^2 - \dfrac{(u_x - v)^2}{c^2}}} = \frac{\left(mc^2 - mvu_x\right)}{\sqrt{\left(1 - v^2/c^2\right)\left(1 - u_x^2/c^2\right)}} = \frac{\dfrac{mc^2}{\sqrt{\left(1 - u_x^2/c^2\right)}} - \dfrac{mvu_x}{\sqrt{\left(1 - u_x^2/c^2\right)}}}{\sqrt{\left(1 - v^2/c^2\right)}}$$

$$= \boxed{\frac{E - p_x v}{\sqrt{\left(1 - v^2/c^2\right)}}}$$

(*b*) We summarize these results, and write the Lorentz transformation from Eq. 36-6, but solved in terms of the primed variables. That can be easily done by interchanged primed and unprimed quantities, and changing v to $-v$.

$$p'_x = \frac{p_x - vE/c^2}{\sqrt{\left(1 - v^2/c^2\right)}} \; ; p'_y = p_y \; ; p'_y = p_y \; ; E' = \frac{E - p_x v}{\sqrt{\left(1 - v^2/c^2\right)}}$$

$$x' = \frac{x - vt}{\sqrt{\left(1 - v^2/c^2\right)}} \;\; ; \;\; y' = y \;\; ; \;\; z' = z \;\; ; \;\; t' = \frac{t - vx/c^2}{\sqrt{\left(1 - v^2/c^2\right)}}$$

These transformations are identical if we exchange p_x with x, p_y with y, p_z with z, and E/c^2 with t (or E/c with ct).

64. The galaxy is moving away from the Earth, and so we use Eq. 36-15b.

$$f_0 - f = 0.0987 f_0 \;\; \rightarrow \;\; f = 0.9013 f_0$$

$$f = f_0\sqrt{\frac{c - v}{c + v}} \;\; \rightarrow \;\; v = \frac{\left[1 - \left(f/f_0\right)^2\right]}{\left[1 + \left(f/f_0\right)^2\right]}c = \left(\frac{1 - 0.9013^2}{1 + 0.9013^2}\right)c = \boxed{0.1035c}$$

65. For source and observer moving towards each other, use Eq. 36-14b.

$$f = f_0\sqrt{\frac{c + v}{c - v}} = f_0\sqrt{\frac{1 + v/c}{1 - v/c}} = (95.0\,\text{MHz})\sqrt{\frac{1 + 0.70}{1 - 0.70}} = 226\,\text{MHz} \approx \boxed{230\,\text{MHz}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

66. We use Eq. 36-15a, and assume that $v \ll c$.

$$\lambda = \lambda_0\sqrt{\frac{c+v}{c-v}} = \lambda_0\sqrt{\frac{1+v/c}{1-v/c}} = \lambda_0\sqrt{\frac{(1+v/c)(1+v/c)}{(1-v/c)(1+v/c)}} = \lambda_0(1+v/c)\sqrt{\frac{1}{(1-v^2/c^2)}}$$

$$= \lambda_0(1+v/c)(1-v^2/c^2)^{-1/2} \approx \lambda_0(1+v/c) = \lambda_0 + \lambda_0 v/c \quad \rightarrow \quad \frac{\lambda-\lambda_0}{\lambda_0} = \boxed{\frac{\Delta\lambda}{\lambda_0} = \frac{v}{c}}$$

67. (*a*) We apply Eq. 36-14b to determine the received/reflected frequency *f*. Then we apply this same equation a second time using the frequency *f* as the source frequency to determine the Doppler-shifted frequency f'. We subtract the initial frequency from this Doppler-shifted frequency to obtain the beat frequency. The beat frequency will be much smaller than the emitted frequency when the speed is much smaller than the speed of light. We then set $c - v \approx c$ and solve for *v*.

$$f = f_0\sqrt{\frac{c+v}{c-v}} \qquad f' = f\sqrt{\frac{c+v}{c-v}} = f_0\sqrt{\frac{c+v}{c-v}}\sqrt{\frac{c+v}{c-v}} = f_0\left(\frac{c+v}{c-v}\right)$$

$$f_{\text{beat}} = f' - f_0 = f_0\left(\frac{c+v}{c-v}\right) - f_0\left(\frac{c-v}{c-v}\right) = f_0\frac{2v}{c-v} \approx f_0\frac{2v}{c} \quad \rightarrow \quad \boxed{v \approx \frac{cf_{\text{beat}}}{2f_0}}$$

$$v \approx \frac{(3.00\times10^8\,\text{m/s})(6670\,\text{Hz})}{2(36.0\times10^9\,\text{Hz})} = \boxed{27.8\,\text{m/s}}$$

(*b*) We find the change in velocity and solve for the resulting change in beat frequency. Setting the change in the velocity equal to 1 km/h we solve for the change in beat frequency.

$$v = \frac{cf_{\text{beat}}}{2f_0} \quad \rightarrow \quad \Delta v = \frac{c\Delta f_{\text{beat}}}{2f_0} \quad \rightarrow \quad \boxed{\Delta f_{\text{beat}} = \frac{2f_0\Delta v}{c}}$$

$$\Delta f_{\text{beat}} = \frac{2(36.0\times10^9\,\text{Hz})(1\,\text{km/h})}{(3.00\times10^8\,\text{m/s})}\left(\frac{1\,\text{m/s}}{3.600\,\text{km/h}}\right) = \boxed{70\,\text{Hz}}$$

68. We consider the difference between Doppler-shifted frequencies for atoms moving directly towards the observer and atoms moving directly away. Use Eqs. 36-14b and 36-15b.

$$\Delta f = f_0\sqrt{\frac{c+v}{c-v}} - f_0\sqrt{\frac{c-v}{c+v}} = f_0\left(\sqrt{\frac{c+v}{c-v}} - \sqrt{\frac{c-v}{c+v}}\right) = f_0\left(\frac{2v}{\sqrt{c^2-v^2}}\right) = f_0\left(\frac{2v/c}{\sqrt{1-v^2/c^2}}\right)$$

We take the speed to be the rms speed of thermal motion, given by Eq. 18-5. We also assume that the thermal energy is much less than the rest energy, and so $3kT \ll mc^2$.

$$v = v_{\text{rms}} = \sqrt{\frac{3kT}{m}} \quad \rightarrow \quad \frac{v}{c} = \sqrt{\frac{3kT}{mc^2}} \quad \rightarrow \quad \frac{\Delta f}{f_0} = 2\sqrt{\frac{3kT}{mc^2}}\left(1-\frac{3kT}{mc^2}\right)^{-1/2} \approx \boxed{2\sqrt{\frac{3kT}{mc^2}}}$$

We evaluate for a gas of H atoms (not H_2 molecules) at 550 K. Use Appendix F to find the mass.

$$\frac{\Delta f}{f_0} = 2\sqrt{\frac{3kT}{mc^2}} = 2\sqrt{\frac{3(1.38\times10^{-23}\,\text{J/K})(550\,\text{K})}{(1.008\,\text{u})(1.66\times10^{-27}\,\text{kg/u})(3.00\times10^8\,\text{m/s})^2}} = \boxed{2.5\times10^{-5}}$$

69. At the North Pole the clock is at rest, while the clock on the equator travels the circumference of the Earth each day. We divide the circumference of the Earth by the length of the day to determine the speed of the equatorial clock. We set the dilated time equal to 2.0 years and solve for the change in rest times for the two clocks.

$$v = \frac{2\pi R}{T} = \frac{2\pi\left(6.38\times10^6\,\text{m}\right)}{\left(24\,\text{hr}\right)\left(3600\,\text{s/hr}\right)} = 464\,\text{m/s}$$

$$\Delta t = \frac{\Delta t_{0,\text{eq}}}{\sqrt{1-v^2/c^2}} \quad\rightarrow\quad \Delta t_{0,\text{eq}} = \Delta t\sqrt{1-v^2/c^2} \approx \Delta t\left(1+\frac{v^2}{2c^2}\right)$$

$$\Delta t = \frac{\Delta t_{0,\text{pole}}}{\sqrt{1-0}} \quad\rightarrow\quad \Delta t_{0,\text{pole}} = \Delta t$$

$$\left|\Delta t_{0,\text{eq}} - \Delta t_{0,\text{pole}}\right| = \Delta t\left(1+\frac{v^2}{2c^2}\right) - \Delta t$$

$$= \Delta t\frac{v^2}{2c^2} = \frac{\left(2.0\,\text{yr}\right)\left(464\,\text{m/s}\right)^2\left(3.156\times10^7\,\text{s/yr}\right)}{2\left(3.00\times10^8\,\text{m/s}\right)^2} = \boxed{75\,\mu\text{s}}$$

70. We take the positive direction in the direction of the motion of the second pod. Consider the first pod as reference frame S, and the spacecraft as reference frame S′. The velocity of the spacecraft relative to the first pod is $v = 0.60c$. The velocity of the first pod relative to the spacecraft is $u_x' = 0.50c$. Solve for the velocity of the second pod relative to the first pod, u_x, using Eq. 36-7a.

$$u_x = \frac{\left(u_x' + v\right)}{\left(1+\frac{vu_x'}{c^2}\right)} = \frac{\left(0.50c + 0.60c\right)}{\left[1+\left(0.60\right)\left(0.50\right)\right]} = \boxed{0.846c}$$

71. We treat the Earth as the stationary frame, and the airplane as the moving frame. The elapsed time in the airplane will be dilated to the observers on the Earth. Use Eq. 36-1a.

$$t_{\text{Earth}} = \frac{2\pi r_{\text{Earth}}}{v} \;;\; t_{\text{plane}} = t_{\text{Earth}}\sqrt{1-v^2/c^2} = \frac{2\pi r_{\text{Earth}}}{v}\sqrt{1-v^2/c^2}$$

$$\Delta t = t_{\text{Earth}} - t_{\text{plane}} = \frac{2\pi r_{\text{Earth}}}{v}\left(1-\sqrt{1-v^2/c^2}\right) \approx \frac{2\pi r_{\text{Earth}}}{v}\left[1-\left(1-\tfrac{1}{2}\frac{v^2}{c^2}\right)\right] = \frac{\pi r_{\text{Earth}} v}{c^2}$$

$$= \frac{\pi\left(6.38\times10^6\,\text{m}\right)\left[1300\,\text{km/h}\left(\frac{1\,\text{m/s}}{3.6\,\text{km/h}}\right)\right]}{\left(3.00\times10^8\,\text{m/s}\right)^2} = \boxed{8.0\times10^{-8}\,\text{s}}$$

72. (*a*) To travelers on the spacecraft, the distance to the star is contracted, according to Eq. 36-3a. This contracted distance is to be traveled in 4.6 years. Use that time with the contracted distance to find the speed of the spacecraft.

$$v = \frac{\Delta x_{\text{spacecraft}}}{\Delta t_{\text{spacecraft}}} = \frac{\Delta x_{\text{Earth}}\sqrt{1-v^2/c^2}}{\Delta t_{\text{spacecraft}}} \quad\rightarrow$$

$$v = c\frac{1}{\sqrt{1+\left(\frac{c\Delta t_{\text{spacecraft}}}{\Delta x_{\text{Earth}}}\right)^2}} = c\frac{1}{\sqrt{1+\left(\frac{4.6\,\text{ly}}{4.3\,\text{ly}}\right)^2}} = 0.6829\,c \approx \boxed{0.68c}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Find the elapsed time according to observers on Earth, using Eq. 36-1a.

$$\Delta t_{\text{Earth}} = \frac{\Delta t_{\text{spaceship}}}{\sqrt{1-v^2/c^2}} = \frac{4.6\,\text{y}}{\sqrt{1-0.6829^2}} = \boxed{6.3\,\text{y}}$$

Note that this agrees with the time found from distance and speed.

$$t_{\text{Earth}} = \frac{\Delta x_{\text{Earth}}}{v} = \frac{4.3\text{ly}}{0.6829c} = 6.3\,\text{yr}$$

73. (*a*) We use Eq. 36-15a. To get a longer wavelength than usual means that the object is moving away from the Earth.

$$\lambda = \lambda_0\sqrt{\frac{c+v}{c-v}} = 1.070\lambda_0 \quad \rightarrow \quad \frac{\left(1.070^2-1\right)}{\left(1.070^2+1\right)}c = v = 0.067c$$

(*b*) We assume that the quasar is moving and the Earth is stationary. Then we use Eq. 16-9b.

$$f = \frac{f_0}{1+v/c} \quad \rightarrow \quad \frac{c}{\lambda} = \frac{c}{\lambda_0}\left(\frac{1}{1+v/c}\right) \quad \rightarrow \quad \lambda = \lambda_0\left(1+v/c\right) = 1.070\lambda_0 \quad \rightarrow \quad v = \boxed{0.070c}$$

74. We assume that some kind of a light signal is being transmitted from the astronaut to Earth, with a frequency of the heartbeat. That frequency will then be Doppler shifted, according to Eq. 36-15b. We express the frequencies in beats per minute.

$$f = f_0\sqrt{\frac{c-v}{c+v}} \quad \rightarrow \quad v = c\frac{\left(f_0^2 - f^2\right)}{\left(f^2 + f_0^2\right)} = c\frac{\left(60^2-30^2\right)}{\left(60^2+30^2\right)} = \boxed{0.60c}$$

75. (*a*) The velocity components of the light in the S′ frame are $u'_x = 0$ and $u'_y = c$. We transform those velocities to the S frame according to Eq. 36-7.

$$u_x = \frac{u'_x + v}{1+vu'_x/c^2} = \frac{0+v}{1+0} = v \;\; ; \;\; u_y = \frac{u'_y\sqrt{1-v^2/c^2}}{1+vu'_x/c^2} = \frac{c\sqrt{1-v^2/c^2}}{1+0} = c\sqrt{1-v^2/c^2}$$

$$\theta = \tan^{-1}\frac{u_y}{u_x} = \tan^{-1}\frac{c\sqrt{1-v^2/c^2}}{v} = \boxed{\tan^{-1}\sqrt{\frac{c^2}{v^2}-1}}$$

(*b*) $u = \sqrt{u_x^2+u_y^2} = \sqrt{v^2+c^2\left(1-v^2/c^2\right)} = \sqrt{v^2+c^2-v^2} = \boxed{c}$

(*c*) In a Galilean transformation, we would have the following.

$$u_x = u'_x + v = v \;\; ; \;\; u_y = u'_y = c \;\; ; \;\; \boxed{u = \sqrt{v^2+c^2}}\left(>c\right) \;\; ; \;\; \boxed{\theta = \tan^{-1}\frac{c}{v}}$$

76. We take the positive direction as the direction of motion of rocket A. Consider rocket A as reference frame S, and the Earth as reference frame S′. The velocity of the Earth relative to rocket A is $v = -0.65c$. The velocity of rocket B relative to the Earth is $u'_x = 0.85c$. Solve for the velocity of rocket B relative to rocket A, u_x, using Eq. 36-7a.

$$u_x = \frac{\left(u'_x + v\right)}{\left(1+\dfrac{vu'_x}{c^2}\right)} = \frac{\left(0.85c - 0.65c\right)}{\left[1+\left(-0.65\right)\left(0.85\right)\right]} = \boxed{0.45c}$$

Note that a Galilean analysis would have resulted in $u_x = 0.20c$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

77. (*a*) We find the speed from Eq. 36-10.

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2 = 14{,}000mc^2 \quad \rightarrow$$

$$v = c\sqrt{1 - \left(\frac{1}{14{,}001}\right)^2} \approx c - \frac{c}{2}\left(\frac{1}{14{,}001}\right)^2 \quad \rightarrow$$

$$c - v = \frac{c}{2}\left(\frac{1}{14{,}001}\right)^2 = \frac{(3.00 \times 10^8 \text{ m/s})}{2}\left(\frac{1}{14{,}001}\right)^2 = \boxed{0.77 \text{ m/s}}$$

(*b*) The tube will be contracted in the rest frame of the electron, according to Eq. 36-3a.

$$\ell_0 = \ell\sqrt{1 - v^2/c^2} = (3.0 \times 10^3 \text{ m})\sqrt{1 - \left[1 - \left(\frac{1}{14{,}001}\right)^2\right]} = \boxed{0.21 \text{ m}}$$

78. The electrostatic force provides the radial acceleration. We solve that relationship for the speed of the electron.

$$|F_{\text{electrostatic}}| = |F_{\text{centripetal}}| \quad \rightarrow \quad \frac{1}{4\pi\varepsilon_0}\frac{e^2}{r^2} = \frac{m_{\text{electron}}v^2}{r} \quad \rightarrow$$

$$v = \sqrt{\frac{1}{4\pi\varepsilon_0}\frac{e^2}{m_{\text{electron}}r}} = \sqrt{\frac{(8.99 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2)}{9.11 \times 10^{-31} \text{kg}}\frac{(1.60 \times 10^{-19} \text{C})^2}{(0.53 \times 10^{-10} \text{m})}} = 2.18 \times 10^6 \text{ m/s} = 0.0073c$$

Because this is much less than 0.1*c*, the electron is not relativistic.

79. The minimum energy required would be the energy to produce the pair with no kinetic energy, so the total energy is their rest energy. They both have the same mass. Use Eq. 36-12.

$$E = 2mc^2 = 2(0.511 \text{MeV}) = \boxed{1.022 \text{ MeV } (1.64 \times 10^{-13} \text{ J})}$$

80. The wattage times the time is the energy required. We use Eq. 36-12 to calculate the mass.

$$E = Pt = mc^2 \quad \rightarrow \quad m = \frac{Pt}{c^2} = \frac{(75 \text{W})(3.16 \times 10^7 \text{s})}{(3.00 \times 10^8 \text{ m/s})^2}\left(\frac{1000 \text{g}}{1 \text{kg}}\right) = \boxed{2.6 \times 10^{-5} \text{g}}$$

81. Use Eqs. 36-13, 36-8, and 36-11.

$$E^2 = p^2c^2 + m^2c^4 \quad \rightarrow \quad E = \left(p^2c^2 + m^2c^4\right)^{1/2} \quad \rightarrow$$

$$\frac{dE}{dp} = \tfrac{1}{2}\left(p^2c^2 + m^2c^4\right)^{-1/2} 2pc^2 = \frac{pc^2}{E} = \frac{pc^2}{E} = \frac{\gamma mvc^2}{\gamma mc^2} = \boxed{v}$$

82. The kinetic energy available comes from the decrease in rest energy.

$$K = m_{\text{n}}c^2 - \left(m_{\text{p}}c^2 + m_e c^2 + m_\nu c^2\right) = 939.57 \text{ MeV} - (938.27 \text{ MeV} + 0.511 \text{MeV} + 0) = \boxed{0.79 \text{ MeV}}$$

83. (*a*) We find the rate of mass loss from Eq. 36-12.

$$E = mc^2 \quad \rightarrow \quad \Delta E = (\Delta m)c^2 \quad \rightarrow$$

$$\frac{\Delta m}{\Delta t} = \frac{1}{c^2}\left(\frac{\Delta E}{\Delta t}\right) = \frac{4 \times 10^{26} \text{ J/s}}{(3.00 \times 10^8 \text{ m/s})^2} = 4.44 \times 10^9 \text{ kg/s} \approx \boxed{4 \times 10^9 \text{ kg/s}}$$

(*b*) Find the time from the mass of the Sun and the rate determined in part (*a*).

$$\Delta t = \frac{m_{\text{Earth}}}{\Delta m/\Delta t} = \frac{\left(5.98\times10^{24}\text{ kg}\right)}{\left(4.44\times10^{9}\text{ kg/s}\right)\left(3.156\times10^{7}\text{ s/y}\right)} = 4.27\times10^{7}\text{ y} \approx \boxed{4\times10^{7}\text{ y}}$$

(*c*) We find the time for the Sun to lose all of its mass at this same rate.

$$\Delta t = \frac{m_{\text{Sun}}}{\Delta m/\Delta t} = \frac{\left(1.99\times10^{30}\text{ kg}\right)}{\left(4.44\times10^{9}\text{ kg/s}\right)\left(3.156\times10^{7}\text{ s/y}\right)} = 1.42\times10^{13}\text{ y} \approx \boxed{1\times10^{13}\text{ y}}$$

84. Use Eq. 36-8 for the momentum to find the mass.

$$p = \gamma mv = \frac{mv}{\sqrt{1-v^2/c^2}} \quad \rightarrow$$

$$m = \frac{p\sqrt{1-v^2/c^2}}{v} = \frac{\left(3.07\times10^{-22}\text{ kg•m/s}\right)\sqrt{1-\left(\dfrac{2.24\times10^{8}\text{ m/s}}{3.00\times10^{8}\text{ m/s}}\right)^2}}{2.24\times10^{8}\text{ m/s}} = 9.12\times10^{-31}\text{kg}$$

This particle has the mass of an electron, and a negative charge, so it must be an electron.

85. The total binding energy is the energy required to provide the increase in rest energy.

$$E = \left[\left(2m_{\text{p+e}} + 2m_{\text{n}}\right) - m_{\text{He}}\right]c^2$$

$$= \left[2\left(1.00783\text{ u}\right) + 2\left(1.00867\text{ u}\right) - 4.00260\text{ u}\right]c^2\left(\frac{931.5\text{ MeV}/c^2}{\text{u}}\right) = \boxed{28.32\text{ MeV}}$$

86. The momentum is given by Eq. 36-8, and the energy is given by Eq. 36-11 and Eq. 36-13.

$$P = \gamma mv = \frac{\gamma mc^2 v}{c^2} = \frac{Ev}{c^2} \quad \rightarrow \quad v = \boxed{\frac{pc^2}{E}} = \frac{pc^2}{\sqrt{m^2c^4 + p^2c^2}} = \boxed{\frac{pc}{\sqrt{m^2c^2 + p^2}}}$$

87. (*a*) The magnitudes of the momenta are equal. We use Eq. 36-8.

$$p = \gamma mv = \frac{mv}{\sqrt{1-v^2/c^2}} = \frac{1}{c}\frac{mc^2\left(v/c\right)}{\sqrt{1-v^2/c^2}} = \frac{1}{c}\frac{\left(938.3\text{MeV}\right)\left(0.985\right)}{\sqrt{1-0.985^2}} = 5356\text{ MeV}/c$$

$$\approx \boxed{5.36\text{GeV}/c} = \left(5.36\text{GeV}/c\right)\left(\frac{1c}{3.00\times10^{8}\text{ m/s}}\right)\left(\frac{1.602\times10^{-10}\text{ J/GeV}}{1\text{GeV}}\right)$$

$$= \boxed{2.86\times10^{-18}\text{ kg•m/s}}$$

(*b*) Because the protons are moving in opposite directions, the vector sum of the momenta is $\boxed{0.}$

(*c*) In the reference frame of one proton, the laboratory is moving at $0.985c$. The other proton is moving at $+0.985c$ relative to the laboratory. We find the speed of one proton relative to the other, and then find the momentum of the moving proton in the rest frame of the other proton by using that relative velocity.

$$u_x = \frac{\left(v + u_x'\right)}{\left(1 + \dfrac{vu_x'}{c^2}\right)} = \frac{\left[0.985c + \left(0.985c\right)\right]}{\left[1 + \left(0.985\right)\left(0.985\right)\right]} \approx 0.9999\,c$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$p = \gamma m u_x = \frac{m u_x}{\sqrt{1 - u_x^2/c^2}} = \frac{1}{c}\frac{mc^2\left(u_x/c\right)}{\sqrt{1 - u_x^2/c^2}} = \frac{1}{c}\frac{\left(938.3\,\text{MeV}\right)\left(\dfrac{2(0.985)}{1+0.985^2}\right)}{\sqrt{1-\left(\dfrac{2(0.985)}{1+0.985^2}\right)^2}} = 62081\,\text{MeV}/c$$

$$\approx \boxed{62.1\,\text{GeV}/c} = \left(62.1\,\text{GeV}/c\right)\left(\frac{1c}{3.00\times10^8\,\text{m/s}}\right)\left(\frac{1.602\times10^{-10}\,\text{J/GeV}}{1\,\text{GeV}}\right)$$

$$= \boxed{3.31\times10^{-17}\,\text{kg•m/s}}$$

88. We find the loss in mass from Eq. 36-12.

$$\Delta m = \frac{E}{c^2} = \frac{484\times10^3\,\text{J}}{\left(3.00\times10^8\,\text{m/s}\right)^2} = \boxed{5.38\times10^{-12}\,\text{kg}}$$

Two moles of water has a mass of $36\times10^{-3}\,\text{kg}$. Find the percentage of mass lost.

$$\frac{5.38\times10^{-12}\,\text{kg}}{36\times10^{-3}\,\text{kg}} = 1.49\times10^{-10} = \boxed{1.5\times10^{-8}\,\%}$$

89. Use Eq. 36-10 for kinetic energy, and Eq. 36-12 for rest energy.

$$K = \left(\gamma - 1\right)m_{\text{Enterprise}}c^2 = m_{\text{converted}}c^2 \quad \rightarrow$$

$$m_{\text{converted}} = \left(\frac{1}{\sqrt{1-v^2/c^2}} - 1\right)m_{\text{Enterprise}} = \left(\frac{1}{\sqrt{1-0.10^2}} - 1\right)\left(6\times10^9\,\text{kg}\right) = \boxed{3\times10^7\,\text{kg}}$$

90. We set the kinetic energy of the spacecraft equal to the rest energy of an unknown mass. Use Eqs. 36-10 and 36-12.

$$K = \left(\gamma - 1\right)m_{\text{ship}}c^2 = mc^2 \quad \rightarrow$$

$$m = \left(\gamma - 1\right)m_{\text{ship}} = \left(\frac{1}{\sqrt{1-v^2/c^2}} - 1\right)m_{\text{ship}} = \left(\frac{1}{\sqrt{1-0.70^2}} - 1\right)\left(1.8\times10^5\,\text{kg}\right) = \boxed{7.2\times10^4\,\text{kg}}$$

From the Earth's point of view, the distance is 35 ly and the speed is 0.70*c*. That data is used to calculate the time from the Earth frame, and then Eq. 36-1a is used to calculate the time in the spaceship frame.

$$\Delta t = \frac{d}{v} = \frac{\left(35\,\text{y}\right)c}{0.70c} = 50\,\text{y} \;\; ; \;\; \Delta t_0 = \Delta t\sqrt{1-v^2/c^2} = \left(50\,\text{y}\right)\sqrt{1-0.70^2} = \boxed{36\,\text{y}}$$

91. We assume one particle is moving in the negative direction in the laboratory frame, and the other particle is moving in the positive direction. We consider the particle moving in the negative direction as reference frame S, and the laboratory as reference frame S′. The velocity of the laboratory relative to the negative-moving particle is $v = 0.85c$, and the velocity of the positive-moving particle relative to the laboratory frame is $u_x' = 0.85c$. Solve for the velocity of the positive-moving particle relative to the negative-moving particle, u_x.

$$u_x = \frac{\left(u_x' + v\right)}{\left(1 + \dfrac{vu_x'}{c^2}\right)} = \frac{\left(0.85c + 0.85c\right)}{\left[1 + \left(0.85\right)\left(0.85\right)\right]} = \boxed{0.987c}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

92. We consider the motion from the reference frame of the spaceship. The passengers will see the trip distance contracted, as given by Eq. 36-3a. They will measure their speed to be that contracted distance divided by the year of travel time (as measured on the ship). Use that speed to find the work done (the kinetic energy of the ship).

$$v = \frac{\ell}{\Delta t_0} = \frac{\ell_0\sqrt{1-v^2/c^2}}{\Delta t_0} \quad \rightarrow \quad \frac{v}{c} = \frac{1}{\left(\sqrt{1+\left(\frac{c\Delta t_0}{\ell_0}\right)^2}\right)} = \frac{1}{\left(\sqrt{1+\left(\frac{1.0\,\text{ly}}{6.6\,\text{ly}}\right)^2}\right)} = 0.9887\,c$$

$$W = \Delta K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2$$

$$= \left(\frac{1}{\sqrt{1 - 0.9887^2}} - 1\right)\left(3.2\times10^4\,\text{kg}\right)\left(3.00\times10^8\,\text{m/s}\right)^2 = \boxed{1.6\times10^{22}\,\text{J}}$$

93. The kinetic energy is given by Eq. 36-10.

$$K = (\gamma - 1)mc^2 = \left(\frac{1}{\sqrt{1-v^2/c^2}} - 1\right)mc^2 = \left(\frac{1}{\sqrt{1-(0.98)^2}} - 1\right)\left(14{,}500\,\text{kg}\right)\left(3.00\times10^8\,\text{m/s}\right)^2$$

$$= \boxed{5.3\times10^{21}\,\text{J}}$$

We compare this with annual U.S. energy consumption: $\dfrac{5.3\times10^{21}\,\text{J}}{10^{20}\,\text{J}} = 53.$

The spaceship's kinetic energy is over 50 times as great.

94. The pi meson decays at rest, and so the momentum of the muon and the neutrino must each have the same magnitude (and opposite directions). The neutrino has no rest mass, and the total energy must be conserved. We combine these relationships using Eq. 36-13.

$$E_\nu = \left(p_\nu{}^2c^2 + m_\nu{}^2c^4\right)^{1/2} = p_\nu c \;\; ; \;\; p_\mu = p_\nu = p$$

$$E_\pi = E_\mu + E_\nu \quad \rightarrow \quad m_\pi c^2 = \left(p_\mu{}^2c^2 + m_\mu{}^2c^4\right)^{1/2} + p_\nu c = \left(p^2c^2 + m_\mu{}^2c^4\right)^{1/2} + pc \quad \rightarrow$$

$$m_\pi c^2 - pc = \left(p^2c^2 + m_\mu{}^2c^4\right)^{1/2} \quad \rightarrow \quad \left(m_\pi c^2 - pc\right)^2 = \left(p^2c^2 + m_\mu{}^2c^4\right)$$

Solve for the momentum.

$$m_\pi{}^2c^4 - 2m_\pi c^2 pc + p^2c^2 = p^2c^2 + m_\mu{}^2c^4 \quad \rightarrow \quad pc = \frac{m_\pi{}^2c^2 - m_\mu{}^2c^2}{2m_\pi}$$

Write the kinetic energy of the muon using Eqs. 36-11 and 36-13.

$$K_\mu = E_\mu - m_\mu c^2 \;\; ; \;\; E_\mu = E_\pi - E_\nu = m_\pi c^2 - pc \quad \rightarrow$$

$$K_\mu = \left(m_\pi c^2 - pc\right) - m_\mu c^2 = m_\pi c^2 - m_\mu c^2 - \frac{\left(m_\pi{}^2c^2 - m_\mu{}^2c^2\right)}{2m_\pi}$$

$$= \frac{2m_\pi\left(m_\pi c^2 - m_\mu c^2\right)}{2m_\pi} - \frac{\left(m_\pi{}^2c^2 - m_\mu{}^2c^2\right)}{2m_\pi}$$

$$= \frac{\left(2m_\pi{}^2 - 2m_\mu m_\pi - m_\pi{}^2 + m_\mu{}^2\right)c^2}{2m_\pi} = \frac{\left(m_\pi{}^2 - 2m_\mu m_\pi + m_\mu{}^2\right)c^2}{2m_\pi} = \boxed{\frac{\left(m_\pi - m_\mu\right)^2c^2}{2m_\pi}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

95. (*a*) The relative speed can be calculated in either frame, and will be the same value in both frames. The time as measured on the Earth will be longer than the time measured on the spaceship, as given by Eq. 36-1a.

$$v = \frac{\Delta x_{\text{Earth}}}{\Delta t_{\text{Earth}}} \;;\; \Delta t_{\text{Earth}} = \frac{\Delta t_{\text{spaceship}}}{\sqrt{1 - v^2/c^2}} = \frac{\Delta t_{\text{spaceship}}}{\sqrt{1 - \left(\dfrac{\Delta x_{\text{Earth}}}{c\Delta t_{\text{Earth}}}\right)^2}} \quad \rightarrow$$

$$\left(\Delta t_{\text{Earth}}\right)^2 - \left(\frac{\Delta x_{\text{Earth}}}{c}\right)^2 = \left(\Delta t_{\text{spaceship}}\right)^2 \quad \rightarrow \quad \left(\Delta t_{\text{Earth}}\right)^2 - \left(\frac{\Delta x_{\text{Earth}}}{c}\right)^2 = \left(\Delta t_{\text{spaceship}}\right)^2 \quad \rightarrow$$

$$\Delta t_{\text{Earth}} = \sqrt{\left(\frac{\Delta x_{\text{Earth}}}{c}\right)^2 + \left(\Delta t_{\text{spaceship}}\right)^2} = \sqrt{(6.0\,\text{y})^2 + (2.50\,\text{y})^2} = \boxed{6.5\,\text{y}}$$

(b) The distance as measured by the spaceship will be contracted.

$$v = \frac{\Delta x_{\text{Earth}}}{\Delta t_{\text{Earth}}} = \frac{\Delta x_{\text{spaceship}}}{\Delta t_{\text{spaceship}}} \quad \rightarrow \quad \Delta x_{\text{spaceship}} = \frac{\Delta t_{\text{spaceship}}}{\Delta t_{\text{Earth}}} \Delta x_{\text{Earth}} = \frac{2.50\,\text{y}}{6.5\,\text{y}}(6.0\,\text{ly}) = \boxed{2.3\,\text{ly}}$$

This is the same distance as found using the length contraction relationship.

96. (*a*) To observers on the ship, the period is non-relativistic. Use Eq. 14-7b.

$$T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{(1.88\,\text{kg})}{(84.2\,\text{N/m})}} = \boxed{0.939\,\text{s}}$$

(*b*) The oscillating mass is a clock. According to observers on Earth, clocks on the spacecraft run slow.

$$T_{\text{Earth}} = \frac{T}{\sqrt{1 - v^2/c^2}} = \frac{(0.939\,\text{s})}{\sqrt{1 - (0.900)^2}} = \boxed{2.15\,\text{s}}$$

97. We use the Lorentz transformations to derive the result.

$$x = \gamma\left(x' + vt'\right) \quad \rightarrow \quad \Delta x = \gamma\left(\Delta x' + v\Delta t'\right) \;;\; t = \gamma\left(t' + \frac{vx'}{c^2}\right) \quad \rightarrow \quad \Delta t = \gamma\left(\Delta t' + \frac{v\Delta x'}{c^2}\right)$$

$$\left(c\Delta t\right)^2 - \left(\Delta x\right)^2 = \left[c\gamma\left(\Delta t' + \frac{v\Delta x'}{c^2}\right)\right]^2 - \left[\gamma\left(\Delta x' + v\Delta t'\right)\right]^2 = \gamma^2\left\{\left[\left(c\Delta t' + \frac{v\Delta x'}{c}\right)\right]^2 - \left(\Delta x' + v\Delta t'\right)\right\}$$

$$= \gamma^2\left\{c^2\left(\Delta t'\right)^2 + 2c\Delta t'\frac{v\Delta x'}{c} + \left(\frac{v\Delta x'}{c}\right)^2 - \left(\Delta x'\right)^2 - 2\Delta x' v\Delta t' - \left(v\Delta t'\right)^2\right\}$$

$$= \frac{1}{\left(1 - v^2/c^2\right)}\left\{\left(c^2 - v^2\right)\left(\Delta t'\right)^2 + \left[\left(\frac{v}{c}\right)^2 - 1\right]\left(\Delta x'\right)^2\right\}$$

$$= \frac{1}{1 - v^2/c^2}\left\{c^2\left(1 - v^2/c^2\right)\left(\Delta t'\right)^2 - \left(1 - v^2/c^2\right)\left(\Delta x'\right)^2\right\}$$

$$= \frac{\left(1 - v^2/c^2\right)}{\left(1 - v^2/c^2\right)}\left\{\left(c\Delta t'\right)^2 - \left(\Delta x'\right)^2\right\} = \left(c\Delta t'\right)^2 - \left(\Delta x'\right)^2$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

98. We assume that the left edge of the glass is even with point A when the flash of light is emitted. There is no loss of generality with that assumption. We do the calculations in the frame of reference in which points A and B are at rest, and the glass is then moving to the right with speed *v*.

If the glass is not moving, we would have this "no motion" result.

$$t_{v=0} = t_{\text{glass}} + t_{\text{vacuum}} = \frac{\text{distance in glass}}{\text{speed in glass}} + \frac{\text{distance in vacuum}}{\text{speed in vacuum}} = \frac{d}{v_{\text{glass}}} + \frac{\ell - d}{c}$$

$$= \frac{d}{c/n} + \frac{\ell - d}{c} = \frac{nd}{c} + \frac{\ell - d}{c} = \frac{nd + \ell - d}{c} = \frac{\ell + (n-1)d}{c}$$

If the index of refraction is $n = 1,$ then the glass will have no effect on the light, and the time would simply be the distance divided by the speed of light.

$$t_{n=1} = t_{\text{glass}} + t_{\text{vacuum}} = \frac{\text{distance in glass}}{\text{speed in glass}} + \frac{\text{distance in vacuum}}{\text{speed in vacuum}} = \frac{d}{c} + \frac{\ell - d}{c} = \frac{d + \ell - d}{c} = \frac{\ell}{c}$$

Now, let us consider the problem from a relativistic point of view. The speed of light in the glass will be the relativistic sum of the speed of light in stationary glass, $c/n,$ and the speed of the glass, *v*, by Eq. 36-7a. We define β to simplify further expressions.

$$v_{\substack{\text{light}\\ \text{in glass}}} = \frac{\frac{c}{n} + v}{1 + \frac{cv}{nc^2}} = \frac{\frac{c}{n} + v}{1 + \frac{v}{nc}} = \frac{c}{n}\frac{\left(1 + \frac{vn}{c}\right)}{\left(1 + \frac{v}{nc}\right)} = \beta\frac{c}{n} \qquad \left[\beta = \frac{\left(1 + \frac{vn}{c}\right)}{\left(1 + \frac{v}{nc}\right)}\right]$$

The contracted width of the glass, from the Earth frame of reference, is given by Eq. 36-3a.

$$d_{\substack{\text{moving}\\ \text{glass}}} = d\sqrt{1 - v^2/c^2} = \frac{d}{\gamma}$$

We assume the light enters the block when the left edge of the block is at point A, and write simple equations for the displacement of the leading edge of the light, and the leading edge of the block. Set them equal and solve for the time when the light exits the right edge of the block.

$$x_{\text{light}} = v_{\substack{\text{light}\\ \text{in glass}}}\, t = \beta\frac{c}{n}t \;\; ; \;\; x_{\substack{\text{right}\\ \text{edge}}} = \frac{d}{\gamma} + vt \;\; ;$$

$$x_{\text{light}} = x_{\substack{\text{right}\\ \text{edge}}} \;\rightarrow\; \beta\frac{c}{n}t_{\text{glass}} = \frac{d}{\gamma} + vt_{\text{glass}} \;\rightarrow\; t_{\text{glass}} = \frac{d}{\gamma}\frac{n}{(\beta c - nv)}$$

Where is the front edge of the block when the light emerges? Use $t_{\text{glass}} = \frac{d}{\gamma}\frac{n}{(\beta c - nv)}$ with either expression – for the leading edge of the light, or the leading edge of the block.

$$x_{\text{light}} = v_{\substack{\text{light}\\ \text{in glass}}}\, t_{\text{glass}} = \beta\frac{c}{n}\frac{d}{\gamma}\frac{n}{(\beta c - nv)} = \frac{\beta cd}{\gamma(\beta c - nv)}$$

$$x_{\substack{\text{right}\\ \text{edge}}} = \frac{d}{\gamma} + vt_{\text{glass}} = \frac{d}{\gamma} + v\frac{d}{\gamma}\frac{n}{(\beta c - nv)} = \frac{d(\beta c - nv) + vdn}{\gamma(\beta c - nv)} = \frac{\beta cd}{\gamma(\beta c - nv)}$$

The part of the path that is left, $\ell - \frac{\beta cd}{\gamma(\beta c - nv)},$ will be traveled at speed *c* by the light. We express that time, and then find the total time.

$$t_{\text{vacuum}} = \frac{\ell - \frac{\beta cd}{\gamma(\beta c - nv)}}{c}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

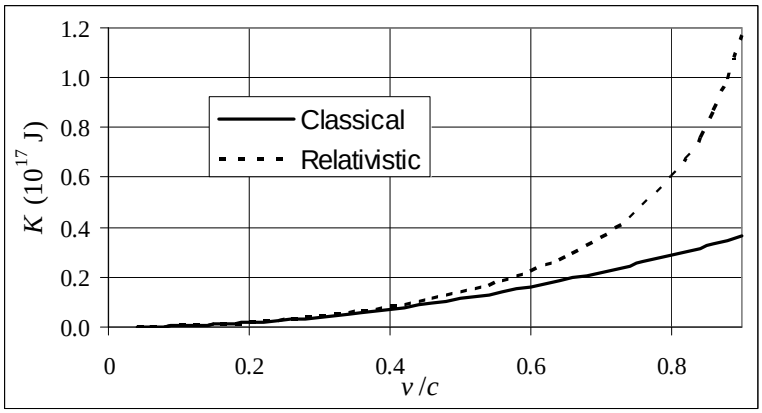
$$t_{\text{total}} = t_{\text{glass}} + t_{\text{vacuum}} = t_{\text{glass}} = \frac{d}{\gamma}\frac{n}{(\beta c - nv)} + \frac{\ell - \dfrac{\beta c d}{\gamma(\beta c - nv)}}{c} = \frac{\ell}{c} + \frac{d}{\gamma}\frac{n-\beta}{(\beta c - nv)}$$

$$= \boxed{\frac{\ell}{c} + \frac{(n-1)d}{c}\sqrt{\frac{c-v}{c+v}}}$$

We check this for the appropriate limiting cases.

Case 1: $t_{\substack{\text{total}\\ v=c}} = \dfrac{\ell}{c} + \dfrac{(n-1)d}{c}\sqrt{\dfrac{c-v}{c+v}} = \dfrac{\ell}{c} + \dfrac{(n-1)d}{c}\sqrt{\dfrac{c-c}{c+c}} = \dfrac{\ell}{c}$

This result was expected, because the speed of the light would always be *c*.



Case 2: $t_{\substack{\text{total}\\ v=0}} = \dfrac{\ell}{c} + \dfrac{(n-1)d}{c}\sqrt{\dfrac{c-v}{c+v}} = \dfrac{\ell}{c} + \dfrac{(n-1)d}{c}(1) = \dfrac{\ell + (n-1)d}{c}$

This result was obtained earlier in the solution.

Case 3: $t_{\substack{\text{total}\\ n=1}} = \dfrac{\ell}{c} + \dfrac{(n-1)d}{c}\sqrt{\dfrac{c-v}{c+v}} = \dfrac{\ell}{c}$

This result was expected, because then there is no speed change in the glass.

99. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH36.XLS," on tab "Problem 36.99."

100. (*a*) We use Eq. 36-98. Since there is motion in two dimensions, we have $\gamma = \dfrac{1}{\sqrt{1 - \dfrac{v_x^2}{c^2} - \dfrac{v_y^2}{c^2}}}$.

$$\vec{\mathbf{F}} = -F\hat{\mathbf{j}} = \frac{d\vec{\mathbf{p}}}{dt} \quad ; \quad \frac{dp_x}{dt} = 0 \;\rightarrow\; p_x = \gamma m v_x = p_0 \quad ; \quad \frac{dp_y}{dt} = -F \;\rightarrow\; p_y = -Ft = \gamma m v_y$$

Use the component equations to obtain expressions for v_x^2 and v_y^2.

$$\gamma m v_x = p_0 \;\rightarrow\; v_x = \frac{p_0}{\gamma m} \;\rightarrow\; v_x^2 = \frac{p_0^2}{\gamma^2 m^2} = \frac{p_0^2}{m^2}\left(1 - \frac{v_x^2}{c^2} - \frac{v_y^2}{c^2}\right) \;\rightarrow\; v_x^2 = p_0^2\frac{\left(c^2 - v_y^2\right)}{\left(m^2c^2 + p_0^2\right)}$$

$$\gamma m v_y = -Ft \;\rightarrow\; v_y = \frac{-Ft}{\gamma m} \;\rightarrow\; v_y^2 = \frac{F^2t^2}{\gamma^2 m^2} = \frac{F^2t^2}{m^2}\left(1 - \frac{v_x^2}{c^2} - \frac{v_y^2}{c^2}\right) \;\rightarrow$$

$$v_y^2 = F^2t^2\frac{\left(c^2 - v_x^2\right)}{\left(m^2c^2 + F^2t^2\right)}$$

Substitute the expression for v_y^2 into the expression for v_x^2.

$$v_x^2 = p_0^2\frac{\left(c^2 - v_y^2\right)}{\left(m^2c^2 + p_0^2\right)} = p_0^2\frac{\left(c^2 - F^2t^2\dfrac{\left(c^2 - v_x^2\right)}{\left(m^2c^2 + F^2t^2\right)}\right)}{\left(m^2c^2 + p_0^2\right)} = p_0^2\frac{\left(m^2c^4 + F^2t^2v_x^2\right)}{\left(m^2c^2 + p_0^2\right)\left(m^2c^2 + F^2t^2\right)} \rightarrow$$

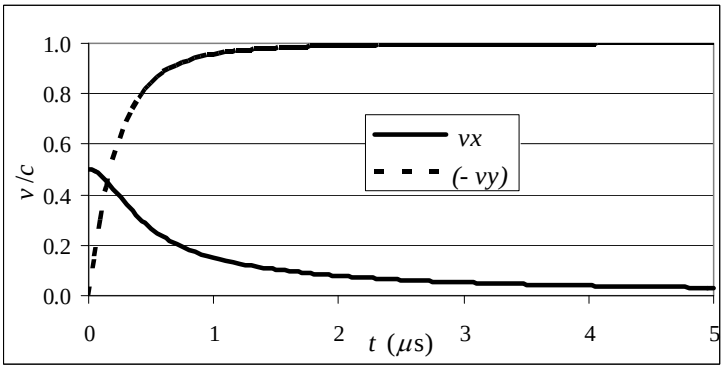
$$v_x^2\left(m^2c^2 + p_0^2\right)\left(m^2c^2 + F^2t^2\right) = p_0^2\left(m^2c^4 + F^2t^2v_x^2\right) \rightarrow$$

$$v_x^2m^4c^4 + v_x^2m^2c^2p_0^2 + v_x^2F^2t^2m^2c^2 + v_x^2F^2t^2p_0^2 = p_0^2m^2c^4 + p_0^2F^2t^2v_x^2 \rightarrow$$

$$v_x^2m^2c^2 + v_x^2p_0^2 + v_x^2F^2t^2 = p_0^2c^2 \rightarrow \boxed{v_x = \frac{p_0c}{\left(m^2c^2 + p_0^2 + F^2t^2\right)^{1/2}}}$$

Use the expression for v_x to solve for v_y.

$$v_y^2 = F^2t^2\frac{\left(c^2 - v_x^2\right)}{\left(m^2c^2 + F^2t^2\right)} = F^2t^2\frac{\left(c^2 - \dfrac{p_0^2c^2}{\left(m^2c^2 + p_0^2 + F^2t^2\right)}\right)}{\left(m^2c^2 + F^2t^2\right)}$$



$$= F^2t^2\frac{\left(c^2\left(m^2c^2 + p_0^2 + F^2t^2\right) - p_0^2c^2\right)}{\left(m^2c^2 + F^2t^2\right)\left(m^2c^2 + p_0^2 + F^2t^2\right)} = F^2t^2\frac{c^2\left(m^2c^2 + F^2t^2\right)}{\left(m^2c^2 + F^2t^2\right)\left(m^2c^2 + p_0^2 + F^2t^2\right)} \rightarrow$$

$$\boxed{v_y = \frac{-Ftc}{\left(m^2c^2 + p_0^2 + F^2t^2\right)^{1/2}}}$$

The negative sign comes from taking the negative square root of the previous equation. We know that the particle is moving down.

(*b*) See the graph. We are plotting v_x/c and $-v_y/c$.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH36.XLS," on tab "Problem 36.100."

(*c*) The path is not parabolic, because the v_x is not constant. Even though there is no force in the *x*-direction, as the net speed of the particle increases, γ increases. Thus v_x must decrease as time elapses in order for p_x to stay constant.

CHAPTER 37: Early Quantum Theory and Models of the Atom

Responses to Questions

1. A reddish star is the coolest, followed by a whitish-yellow star. Bluish stars have the highest temperatures. The temperature of the star is related to the frequency of the emitted light. Since red light has a lower frequency than blue light, red stars have a lower temperature than blue stars.

2. The energy radiated by an object may not be in the visible part of the electromagnetic spectrum. The spectrum of a blackbody with a temperature of 1000 K peaks in the IR and the object appears red, since it includes some radiation at the red end of the visible spectrum. Cooler objects will radiate less overall energy and peak at even longer wavelengths. Objects that are cool enough will not radiate any energy at visible wavelengths.

3. The lightbulb will not produce light as white as the Sun, since the peak of its emitted light is in the infrared. The lightbulb will appear more yellowish than the Sun, which has a spectrum that peaks in the visible range.

4. A bulb which appears red would emit very little radiant energy at higher visible frequencies and therefore would not expose black and white photographic paper. This strategy would not work in a darkroom for developing color photographs since the photographic paper would be sensitive to light at all visible frequencies, including red.

5. If the threshold wavelength increases for the second metal, then it has a smaller work function than the first metal. Longer wavelength corresponds to lower energy. It will take less energy for the electron to escape the surface of the second metal.

6. According to the wave theory, light of any frequency can cause electrons to be ejected as long as the light is intense enough. A higher intensity corresponds to a greater electric field magnitude and more energy. Therefore, there should be no frequency below which the photoelectric effect does not occur. According to the particle theory, however, each photon carries an amount of energy which depends upon its frequency. Increasing the intensity of the light increases the number of photons but does not increase the energy of the individual photons. The cutoff frequency is that frequency at which the energy of the photon equals the work function. If the frequency of the incoming light is below the cutoff, the electrons will not be ejected because no individual photon has enough energy to impart to an electron.

7. Individual photons of ultraviolet light are more energetic than photons of visible light and will deliver more energy to the skin, causing burns. UV photons also can penetrate farther into the skin, and, once at the deeper level, can deposit a large amount of energy that can cause damage to cells.

8. Cesium will give a higher maximum kinetic energy for the electrons. Cesium has a lower work function, so more energy is available for the kinetic energy of the electrons.

9. (*a*) No. The energy of a beam of photons depends not only on the energy of each individual photon but also on the total number of photons. If there are enough infrared photons, the infrared beam may have more energy than the ultraviolet beam.
   (*b*) Yes. The energy of a single photon depends on its frequency: $E = hf$. Since infrared light has a lower frequency than ultraviolet light, a single IR photon will always have less energy than a single UV photon.

10. Fewer electrons are emitted from the surface struck by the 400 nm photons. Each 400 nm photon has a higher energy than each 450 nm photon, so it will take fewer 400 nm photons to produce the same intensity (energy per unit area per unit time) as the 450 nm photon beam. The maximum kinetic energy of the electrons emitted from the surface struck by the 400 nm photons will be greater than the maximum kinetic energy of the electrons emitted from the surface struck by the 450 nm photons, again because each 400 nm photon has a higher energy.

11. (*a*) In a burglar alarm, when the light beam is interrupted (by an intruder, or a door or window opening), the current stops flowing in the circuit. An alarm could be set to go off when the current stops.
    (*b*) In a smoke detector, when the light beam is obscured by smoke, the current in the circuit would decrease or stop. An alarm could be set to go off when the current decreased below a certain level.
    (*c*) The amount of current in the circuit depends on the intensity of the light, as long as the frequency of the light is above the threshold frequency. The ammeter in the circuit could be calibrated to reflect the light intensity.

12. Yes, the wavelength increases. In the scattering process, some of the energy of the incident photon is transferred to the electron, so the scattered photon has less energy, and therefore a lower frequency and longer wavelength, than the incident photon. ($E = hf = hc/\lambda$.)

13. In the photoelectric effect the photon energy is completely absorbed by the electron. In the Compton effect, the photon is scattered from the electron and travels off at a lower energy.

14. According to both the wave theory and the particle theory the intensity of a point source of light decreases as the inverse square of the distance from the source. In the wave theory, the intensity of the waves obeys the inverse square law. In the particle theory, the surface area of a sphere increases with the square of the radius, and therefore the density of particles decreases with distance, obeying the inverse square law. The variation of intensity with distance cannot be used to help distinguish between the two theories.

15. The proton will have the shorter wavelength, since it has a larger mass than the electron and therefore a larger momentum $(\lambda = h/p)$.

16. Light demonstrates characteristics of both waves and particles. Diffraction and interference are wave characteristics, and are demonstrated, for example, in Young's double-slit experiment. The photoelectric effect and Compton scattering are examples of experiments in which light demonstrates particle characteristics. We can't say that light IS a wave or a particle, but it has properties of each.

17. Electrons demonstrate characteristics of both waves and particles. Electrons act like waves in electron diffraction and like particles in the Compton effect and other collisions.

18. Both a photon and an electron have properties of waves and properties of particles. They can both be associated with a wavelength and they can both undergo scattering. An electron has a negative charge and a rest mass, obeys the Pauli exclusion principle, and travels at less than the speed of light. A photon is not charged, has no rest mass, does not obey the Pauli exclusion principle, and travels at the speed of light.

19. Opposite charges attract, so the attractive Coulomb force between the positive nucleus and the negative electrons keeps the electrons from flying off into space.

20. Look at a solar absorption spectrum, measured above the Earth's atmosphere. If there are dark (absorption) lines at the wavelengths corresponding to oxygen transitions, then there is oxygen near the surface of the Sun.

21. At room temperature, nearly all the atoms in hydrogen gas will be in the ground state. When light passes through the gas, photons are absorbed, causing electrons to make transitions to higher states and creating absorption lines. These lines correspond to the Lyman series since that is the series of transitions involving the ground state or n = 1 level. Since there are virtually no atoms in higher energy states, photons corresponding to transitions from $n \geq 2$ to higher states will not be absorbed.

22. The closeness of the spacing between energy levels near the top of Figure 37-26 indicates that the energy differences between these levels are small. Small energy differences correspond to small wavelength differences, leading to the closely spaced spectral lines in Figure 37-21.

23. There is no direct connection between the size of a particle and its de Broglie wavelength. It is possible for the wavelength to be smaller or larger than the particle.

24. On average the electrons of helium are closer to the nucleus than the electrons of hydrogen. The nucleus of helium contains two protons (positive charges), and so attracts each electron more strongly than the single proton in the nucleus of hydrogen. (There is some shielding of the nuclear charge by the second electron, but each electron still feels the attractive force of more than one proton's worth of charge.)

25. The lines in the spectrum of hydrogen correspond to all the possible transitions that the electron can make. The Balmer lines, for example, correspond to an electron moving from all higher energy levels to the n = 2 level. Although an individual hydrogen atom only contains one electron, a sample of hydrogen gas contains many atoms and all the different atoms will be undergoing different transitions.

26. The Balmer series spectral lines are in the visible light range and could be seen by early experimenters without special detection equipment.

27. The photon carries momentum, so according to conservation of momentum, the hydrogen atom will recoil as the photon is ejected. Some of the energy emitted in the transition of the atom to a lower energy state will be the kinetic energy of the recoiling atom, so the photon will have slightly less energy than predicted by the simple difference in energy levels.

28. No. At room temperature, virtually all the atoms in a sample of hydrogen gas will be in the ground state. Thus, the absorption spectrum will contain primarily just the Lyman lines, as photons corresponding to transitions from the n = 1 level to higher levels are absorbed. Hydrogen at very high temperatures will have atoms in excited states. The electrons in the higher energy levels will fall to all lower energy levels, not just the n = 1 level. Therefore, emission lines corresponding to transitions to levels higher than n = 1 will be present as well as the Lyman lines. In general, you would expect to see only Lyman lines in the absorption spectrum of room temperature hydrogen, but you would find Lyman, Balmer, Paschen, and other lines in the emission spectrum of high-temperature hydrogen.

Solutions to Problems

In several problems, the value of *hc* is needed. We often use the result of Problem 96, $hc = 1240\,\text{eV}\cdot\text{nm}$.

1. We use Wien's law, Eq. 37-1.

(*a*) $\lambda_p = \dfrac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{T} = \dfrac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{(273\,\text{K})} = 1.06\times10^{-5}\,\text{m} = \boxed{10.6\,\mu\text{m}}$

This wavelength is in the far infrared.

(*b*) $\lambda_p = \dfrac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{T} = \dfrac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{(3500\,\text{K})} = 8.29\times10^{-7}\,\text{m} = \boxed{829\,\text{nm}}$

This wavelength is in the infrared.

(*c*) $\lambda_p = \dfrac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{T} = \dfrac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{(4.2\,\text{K})} = 6.90\times10^{-4}\,\text{m} = \boxed{0.69\,\text{mm}}$

This wavelength is in the microwave region.

(*d*) $\lambda_p = \dfrac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{T} = \dfrac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{(2.725\,\text{K})} = 1.06\times10^{-3}\,\text{m} = \boxed{1.06\,\text{mm}}$

This wavelength is in the microwave region.

2. We use Wien's law to find the temperature for a peak wavelength of 460 nm.

$$T = \frac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{\lambda_p} = \frac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{(460\times10^{-9}\,\text{m})} = \boxed{6300\,\text{K}}$$

3. Because the energy is quantized according to Eq. 37-2, the difference in energy between adjacent levels is simply $E = nhf$.

$$\Delta E = hf = (6.63\times10^{-34}\,\text{J}\cdot\text{s})(8.1\times10^{13}\,\text{Hz}) = \boxed{5.4\times10^{-20}\,\text{J} = 0.34\,\text{eV}}$$

4. We use Eq. 37-1 with a temperature of $98^\circ\text{F} = 37^\circ\text{C} = 310\,\text{K}$.

$$\lambda_p = \frac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{T} = \frac{(2.90\times10^{-3}\,\text{m}\cdot\text{K})}{(310\,\text{K})} = 9.4\times10^{-6}\,\text{m} = \boxed{9.4\,\mu\text{m}}$$

5. (*a*) Wien's displacement law says that $\lambda_p T =$ constant. We must find the wavelength at which $I(\lambda, T)$ is a maximum for a given temperature. This can be found by setting $\partial I/\partial\lambda = 0$.

$$\frac{\partial I}{\partial\lambda} = \frac{\partial}{\partial\lambda}\left(\frac{2\pi hc^2\lambda^{-5}}{e^{hc/\lambda kT}-1}\right) = 2\pi hc^2\frac{\partial}{\partial\lambda}\left(\frac{\lambda^{-5}}{e^{hc/\lambda kT}-1}\right)$$

$$= 2\pi hc^2\left[\frac{\left(e^{hc/\lambda kT}-1\right)\left(-5\lambda^{-6}\right)-\lambda^{-5}e^{hc/\lambda kT}\left(-\dfrac{hc}{kT\lambda^2}\right)}{\left(e^{hc/\lambda kT}-1\right)^2}\right]$$

$$= \frac{2\pi hc^2}{\lambda^6\left(e^{hc/\lambda kT}-1\right)^2}\left[5+e^{hc/\lambda kT}\left(\frac{hc}{kT\lambda}-5\right)\right] = 0 \;\rightarrow\; 5 = e^{hc/\lambda kT}\left(5-\frac{hc}{kT\lambda}\right) \;\rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$e^x(5-x)=5\ ;\ x=\frac{hc}{\lambda_p kT}$$

This transcendental equation will have some solution x = constant, and so $\frac{hc}{\lambda_p kT}$ = constant, and so $\boxed{\lambda_p T = \text{constant}}$. The constant could be evaluated from solving the transcendental equation,

(*b*) To find the value of the constant, we solve $e^x(5-x)=5$, or $5-x=5e^{-x}$. This can be done graphically, by graphing both $y=5-x$ and $y=5e^{-x}$ on the same set of axes and finding the intersection point. Or, the quantity $5-x-5e^{-x}$ could be calculated, and find for what value of x that expression is 0. The answer is x = 4.966. We use this value to solve for h. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH37.XLS," on tab "Problem 37.5."

$$\frac{hc}{\lambda_p kT}=4.966 \ \rightarrow$$

$$h=4.966\frac{\lambda_p Tk}{c}=4.966\frac{\left(2.90\times10^{-3}\,\text{m•K}\right)\left(1.38\times10^{-23}\,\text{J/K}\right)}{3.00\times10^{8}\,\text{m/s}}=\boxed{6.62\times10^{-34}\,\text{J•s}}$$

(*c*) We integrate Planck's radiation formula over all wavelengths.

$$\int_0^\infty I(\lambda,T)\,d\lambda=\int_0^\infty\left(\frac{2\pi hc^2\lambda^{-5}}{e^{hc/\lambda kT}-1}\right)d\lambda\ ;\ \text{let}\ \frac{hc}{\lambda kT}=x\ ;\ \lambda=\frac{hc}{xkT}\ ;\ d\lambda=-\frac{hc}{x^2kT}dx$$

$$\int_0^\infty I(\lambda,T)\,d\lambda=\int_0^\infty\left(\frac{2\pi hc^2\lambda^{-5}}{e^{hc/\lambda kT}-1}\right)d\lambda=\int_\infty^0\left(\frac{2\pi hc^2\left(\frac{hc}{xkT}\right)^{-5}}{e^x-1}\right)\left(-\frac{hc}{x^2kT}dx\right)=\frac{2\pi k^4T^4}{h^3c^2}\int_0^\infty\left(\frac{x^3}{e^x-1}\right)dx$$

$$=\frac{2\pi k^4}{h^3c^2}\left[\int_0^\infty\left(\frac{x^3}{e^x-1}\right)dx\right]T^4\propto T^4$$

Thus the total radiated power per unit area is proportional to T^4. Everything else in the expression is constant with respect to temperature.

6. We use Eq. 37-3.

$$E=hf=\left(6.626\times10^{-34}\,\text{J•s}\right)\left(104.1\times10^{6}\,\text{Hz}\right)=\boxed{6.898\times10^{-26}\,\text{J}}$$

7. We use Eq. 37-3 along with the fact that $f=c/\lambda$ for light. The longest wavelength will have the lowest energy.

$$E_1=hf_1=\frac{hc}{\lambda_1}=\frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(410\times10^{-9}\,\text{m}\right)}=4.85\times10^{-19}\,\text{J}\left(\frac{1\text{eV}}{1.60\times10^{-19}\,\text{J}}\right)=3.03\text{eV}$$

$$E_2=hf_2=\frac{hc}{\lambda_2}=\frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(750\times10^{-9}\,\text{m}\right)}=2.65\times10^{-19}\,\text{J}\left(\frac{1\text{eV}}{1.60\times10^{-19}\,\text{J}}\right)=1.66\text{eV}$$

Thus the range of energies is $\boxed{2.7\times10^{-19}\,\text{J}<E<4.9\times10^{-19}\,\text{J}}$ or $\boxed{1.7\,\text{eV}<E<3.0\,\text{eV}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8. We use Eq. 37-3 with the fact that $f = c/\lambda$ for light.

$$\lambda = \frac{c}{f} = \frac{hc}{E} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\left(380\times10^{3}\,\text{eV}\right)} = 3.27\times10^{-12}\,\text{m} \approx \boxed{3.3\times10^{-3}\,\text{nm}}$$

Significant diffraction occurs when the opening is on the order of the wavelength. Thus there would be insignificant diffraction through the doorway.

9. We use Eq. 37-3 with the fact that $f = c/\lambda$ for light.

$$E_{\min} = hf_{\min} \;\rightarrow\; f_{\min} = \frac{E_{\min}}{h} = \frac{(0.1\text{eV})\left(1.60\times10^{-19}\,\text{J/eV}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)} = 2.41\times10^{13}\,\text{Hz} \approx \boxed{2\times10^{13}\,\text{Hz}}$$

$$\lambda_{\max} = \frac{c}{f_{\min}} = \frac{\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(2.41\times10^{13}\,\text{Hz}\right)} = 1.24\times10^{-5}\,\text{m} \approx \boxed{1\times10^{-5}\,\text{m}}$$

10. We use Eq. 37-5.

$$p = \frac{h}{\lambda} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(6.20\times10^{-7}\,\text{m}\right)} = \boxed{1.07\times10^{-27}\,\text{kg•m/s}}$$

11. At the minimum frequency, the kinetic energy of the ejected electrons is 0. Use Eq. 37-4a.

$$K = hf_{\min} - W_0 = 0 \;\rightarrow\; f_{\min} = \frac{W_0}{h} = \frac{4.8\times10^{-19}\,\text{J}}{6.63\times10^{-34}\,\text{J•s}} = \boxed{7.2\times10^{14}\,\text{Hz}}$$

12. The longest wavelength corresponds to the minimum frequency. That occurs when the kinetic energy of the ejected electrons is 0. Use Eq. 37-4a.

$$K = hf_{\min} - W_0 = 0 \;\rightarrow\; f_{\min} = \frac{c}{\lambda_{\max}} = \frac{W_0}{h} \;\rightarrow$$

$$\lambda_{\max} = \frac{ch}{W_0} = \frac{\left(3.00\times10^{8}\,\text{m/s}\right)\left(6.63\times10^{-34}\,\text{J•s}\right)}{(3.70\,\text{eV})\left(1.60\times10^{-19}\,\text{J/eV}\right)} = \boxed{3.36\times10^{-7}\,\text{m}} = 336\,\text{nm}$$

13. The energy of the photon will equal the kinetic energy of the baseball. We use Eq. 37-3.

$$K = hf \;\rightarrow\; \tfrac{1}{2}mv^2 = h\frac{c}{\lambda} \;\rightarrow\; \lambda = \frac{2hc}{mv^2} = \frac{2\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{(0.145\,\text{kg})(30.0\,\text{m/s})^2} = \boxed{3.05\times10^{-27}\,\text{m}}$$

14. We divide the minimum energy by the photon energy at 550 nm to find the number of photons.

$$E = nhf = E_{\min} \;\rightarrow\; n = \frac{E_{\min}}{hf} = \frac{E_{\min}\lambda}{hc} = \frac{\left(10^{-18}\,\text{J}\right)\left(550\times10^{-9}\,\text{m}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)} = 2.77 \approx \boxed{3\text{ photons}}$$

15. The photon of visible light with the maximum energy has the least wavelength. We use 410 nm as the lowest wavelength of visible light.

$$hf_{\max} = \frac{hc}{\lambda_{\min}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\left(410\times10^{-9}\,\text{m}\right)} = 3.03\text{eV}$$

Electrons will not be emitted if this energy is less than the work function.
The metals with work functions greater than 3.03 eV are copper and iron.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16. (*a*) At the threshold wavelength, the kinetic energy of the photoelectrons is zero, so the work function is equal to the energy of the photon.

$$W_0 = hf - K_{\max} = hf = \frac{hc}{\lambda} = \frac{1240\,\text{eV}\cdot\text{nm}}{520\,\text{nm}} = \boxed{2.4\,\text{eV}}$$

(*b*) The stopping voltage is the voltage that gives a potential energy change equal to the maximum kinetic energy. We use Eq. 37-4b to calculate the maximum kinetic energy.

$$K_{\max} = hf - W_0 = \frac{hc}{\lambda} - W_0 = \frac{1240\,\text{eV}\cdot\text{nm}}{470\,\text{nm}} - 2.38\,\text{eV} = 0.25\,\text{eV}$$

$$V_0 = \frac{K_{\max}}{e} = \frac{0.25\,\text{eV}}{e} = \boxed{0.25\,\text{V}}$$

17. The photon of visible light with the maximum energy has the minimum wavelength. We use Eq. 37-4b to calculate the maximum kinetic energy.

$$K_{\max} = hf - W_0 = \frac{hc}{\lambda} - W_0 = \frac{1240\ \text{eV}\cdot\text{nm}}{410\ \text{nm}} - 2.48\ \text{eV} = \boxed{0.54\ \text{eV}}$$

18. We use Eq. 37-4b to calculate the maximum kinetic energy. Since the kinetic energy is much less than the rest energy, we use the classical definition of kinetic energy to calculate the speed.

$$K_{\max} = hf - W_0 = \frac{hc}{\lambda} - W_0 = \frac{1240\,\text{eV}\cdot\text{nm}}{365\,\text{nm}} - 2.48\,\text{eV} = \boxed{0.92\,\text{eV}}$$

$$K_{\max} = \tfrac{1}{2}mv^2 \quad \rightarrow \quad v = \sqrt{\frac{2K_{\max}}{m}} = \sqrt{\frac{2\left(0.92\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}{9.11\times10^{-31}\,\text{kg}}} = \boxed{5.7\times10^5\,\text{m/s}}$$

19. We use Eq. 37-4b to calculate the work function.

$$W_0 = hf - K_{\max} = \frac{hc}{\lambda} - K_{\max} = \frac{1240\ \text{eV}\cdot\text{nm}}{285\ \text{nm}} - 1.70\ \text{eV} = \boxed{2.65\ \text{eV}}$$

20. Electrons emitted from photons at the threshold wavelength have no kinetic energy. We use Eq. 37-4b with the threshold wavelength to determine the work function.

$$W_0 = \frac{hc}{\lambda} - K_{\max} = \frac{hc}{\lambda_{\max}} = \frac{1240\ \text{eV}\cdot\text{nm}}{320\ \text{nm}} = 3.88\ \text{eV}.$$

(*a*) We now use Eq. 36-4b with the work function determined above to calculate the kinetic energy of the photoelectrons emitted by 280 nm light.

$$K_{\max} = \frac{hc}{\lambda} - W_0 = \frac{1240\ \text{eV}\cdot\text{nm}}{280\ \text{nm}} - 3.88\ \text{eV} = \boxed{0.55\ \text{eV}}$$

(*b*) Because the wavelength is greater than the threshold wavelength, the photon energy is less than the work function, so there will be no ejected electrons.

21. The stopping voltage is the voltage that gives a potential energy change equal to the maximum kinetic energy of the photoelectrons. We use Eq. 37-4b to calculate the work function where the maximum kinetic energy is the product of the stopping voltage and electron charge.

$$W_0 = \frac{hc}{\lambda} - K_{\max} = \frac{hc}{\lambda} - eV_0 = \frac{1240\ \text{eV}\cdot\text{nm}}{230\ \text{nm}} - \left(1.84\ \text{V}\right)e = \boxed{3.55\ \text{eV}}$$

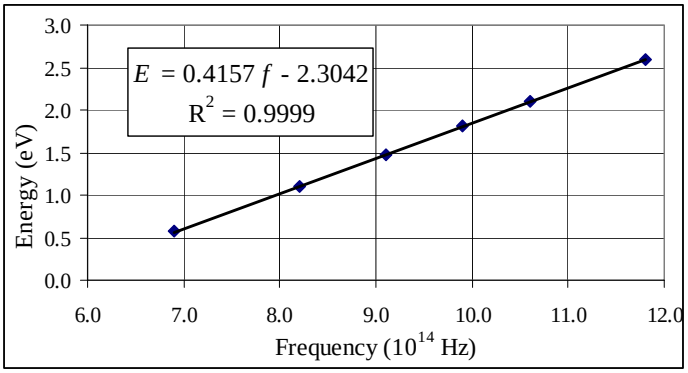
22. The energy required for the chemical reaction is provided by the photon. We use Eq. 37-3 for the energy of the photon, where $f = c/\lambda$.

$$E = hf = \frac{hc}{\lambda} = \frac{1240\ \text{eV•nm}}{630\ \text{nm}} = \boxed{2.0\ \text{eV}}$$

Each reaction takes place in a molecule, so we use the appropriate conversions to convert eV/molecule to kcal/mol.

$$E = \left(\frac{2.0\ \text{eV}}{\text{molecule}}\right)\left(\frac{1.60\times10^{-19}\ \text{J}}{\text{eV}}\right)\left(\frac{6.02\times10^{23}\ \text{molecules}}{\text{mol}}\right)\left(\frac{\text{kcal}}{4186\ \text{J}}\right) = \boxed{45\ \text{kcal/mole}}$$



23. (*a*) Since $f = c/\lambda$, the photon energy given by Eq. 37-3 can be written in terms of the wavelength as $E = hc/\lambda$. This shows that the photon with the largest wavelength has the smallest energy. The 750-nm photon then delivers the minimum energy that will excite the retina.

$$E = \frac{hc}{\lambda} = \frac{\left(6.63\times10^{-34}\ \text{J•s}\right)\left(3.00\times10^{8}\ \text{m/s}\right)}{\left(750\times10^{-9}\ \text{m}\right)}\left(\frac{1\ \text{eV}}{1.60\times10^{-19}\ \text{J}}\right) = \boxed{1.66\ \text{eV}}$$

(*b*) The eye cannot see light with wavelengths less than 410 nm. Obviously, these wavelength photons have more energy than the minimum required to initiate vision, so they must not arrive at the retina. That is, wavelength less than 410 nm are absorbed near the front portion of the eye. The threshold photon energy is that of a 410-nm photon.

$$E = \frac{hc}{\lambda} = \frac{\left(6.63\times10^{-34}\ \text{J•s}\right)\left(3.00\times10^{8}\ \text{m/s}\right)}{\left(410\times10^{-9}\ \text{m}\right)}\left(\frac{1\ \text{eV}}{1.60\times10^{-19}\ \text{J}}\right) = \boxed{3.03\ \text{eV}}$$

24. We plot the maximum (kinetic) energy of the emitted electrons vs. the frequency of the incident radiation. Eq. 37-4b says $K_{\max} = hf - W_0$. The best-fit straight line is determined by linear regression in Excel. The slope of the best-fit straight line to the data should give Planck's constant, the *x*-intercept is the cutoff frequency, and the *y*-intercept is the opposite of the work function. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH37.XLS," on tab "Problem 37.24."

(*a*) $h = \left(0.4157\,\text{eV}/10^{14}\text{Hz}\right)\left(1.60\times10^{-19}\ \text{J/eV}\right) = \boxed{6.7\times10^{-34}\ \text{J•s}}$

(*b*) $hf_{\text{cutoff}} = W_0 \rightarrow f_{\text{cutoff}} = \frac{W_0}{h} = \frac{2.3042\,\text{eV}}{\left(0.4157\,\text{eV}/10^{14}\text{Hz}\right)} = \boxed{5.5\times10^{14}\ \text{Hz}}$

(*c*) $W_0 = \boxed{2.3\text{eV}}$

25. (*a*) Since $f = c/\lambda$, the photon energy is $E = hc/\lambda$ and the largest wavelength has the smallest energy. In order to eject electrons for all possible incident visible light, the metal's work function must be less than or equal to the energy of a 750-nm photon. Thus the maximum value for the metal's work function W_0 is found by setting the work function equal to the energy of the 750-nm photon.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$W_o = \frac{hc}{\lambda} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(750\times10^{-9}\,\text{m}\right)}\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = \boxed{1.66\,\text{eV}}$$

(*b*) If the photomultiplier is to function only for incident wavelengths less than 410-nm, then we set the work function equal to the energy of the 410-nm photon.

$$W_o = \frac{hc}{\lambda} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(410\times10^{-9}\,\text{m}\right)}\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = \boxed{3.03\,\text{eV}}$$

26. Since $f = c/\lambda$, the energy of each emitted photon is $E = hc/\lambda$. We multiply the energy of each photon by $1.0\times10^{6}/\text{s}$ to determine the average power output of each atom. At distance of $r = 25\,\text{cm}$, the light sensor measures an intensity of $I = 1.6\,\text{nW}/1.0\,\text{cm}^2$. Since light energy emitted from atoms radiates equally in all directions, the intensity varies with distance as a spherical wave. Thus, from Section 15–3 in the text, the average power emitted is $\bar{P} = 4\pi r^2 I$. Dividing the total average power by the power from each atom gives the number of trapped atoms.

$$N = \frac{\bar{P}}{\bar{P}_{\text{atom}}} = \frac{4\pi r^2 I}{nhc/\lambda} = \frac{4\pi\left(25\text{cm}\right)^2\left(1.6\times10^{-9}\,\text{W/cm}^2\right)}{\left(1.0\times10^{6}/\text{s}\right)\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)/\left(780\times10^{-9}\,\text{m}\right)}$$

$$= \boxed{4.9\times10^{7}\,\text{atoms}}$$

27. We set the kinetic energy in Eq. 37-4b equal to the stopping voltage, eV_0, and write the frequency of the incident light in terms of the wavelength, $f = c/\lambda$. We differentiate the resulting equation and solve for the fractional change in wavelength, and we take the absolute value of the final expression.

$$eV_0 = \frac{hc}{\lambda} - W_0 \;\rightarrow\; e\,dV_0 = -\frac{hc}{\lambda^2}d\lambda \;\rightarrow\; \frac{d\lambda}{\lambda} = -\frac{e\,dV_0\lambda}{hc} \;\approx\; \boxed{\frac{\Delta\lambda}{\lambda} = \frac{e\lambda}{hc}\Delta V_0}$$

$$\frac{\Delta\lambda}{\lambda} = \frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(550\times10^{-9}\,\text{m}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}\left(0.01\,\text{V}\right) = \boxed{0.004}$$

28. We use Eq. 37-6b. Note that the answer is correct to two significant figures.

$$\Delta\lambda = \frac{h}{m_e c}\left(1-\cos\phi\right) \;\rightarrow$$

$$\phi = \cos^{-1}\left(1-\frac{m_e c\Delta\lambda}{h}\right) = \cos^{-1}\left(1-\frac{\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)\left(1.5\times10^{-13}\,\text{m}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)}\right) = \boxed{20^\circ}$$

29. The Compton wavelength for a particle of mass *m* is h/mc.

(*a*) $$\frac{h}{m_e c} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)} = \boxed{2.43\times10^{-12}\,\text{m}}$$

(*b*) $$\frac{h}{m_p c} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(1.67\times10^{-27}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)} = \boxed{1.32\times10^{-15}\,\text{m}}$$

(*c*) The energy of the photon is given by Eq. 37-3.

$$E_{\text{photon}} = hf = \frac{hc}{\lambda} = \frac{hc}{\left(h/mc\right)} = mc^2 = \text{rest energy}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

30. We find the Compton wavelength shift for a photon scattered from an electron, using Eq. 37-6b. The Compton wavelength of a free electron is given in the text right after Eq. 37-6b.

$$\lambda' - \lambda = \left(\frac{h}{m_e c}\right)(1-\cos\theta) = \lambda_C(1-\cos\theta) = \left(2.43\times10^{-3}\,\text{nm}\right)(1-\cos\theta)$$

(*a*) $\lambda'_a - \lambda = \left(2.43\times10^{-3}\,\text{nm}\right)(1-\cos 60°) = \boxed{1.22\times10^{-3}\,\text{nm}}$

(*b*) $\lambda'_b - \lambda = \left(2.43\times10^{-3}\,\text{nm}\right)(1-\cos 90°) = \boxed{2.43\times10^{-3}\,\text{nm}}$

(*c*) $\lambda'_c - \lambda = \left(2.43\times10^{-3}\,\text{nm}\right)(1-\cos 180°) = \boxed{4.86\times10^{-3}\,\text{nm}}$

31. (*a*) In the Compton effect, the maximum change in the photon's wavelength is when scattering angle $\phi = 180°$. We use Eq. 37-6b to determine the maximum change in wavelength. Dividing the maximum change by the initial wavelength gives the maximum fractional change.

$$\Delta\lambda = \frac{h}{m_e c}(1-\cos\theta) \quad \rightarrow$$

$$\frac{\Delta\lambda}{\lambda} = \frac{h}{m_e c\lambda}(1-\cos\theta) = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)(1-\cos 180°)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)\left(550\times10^{-9}\,\text{m}\right)} = \boxed{8.8\times10^{-6}}$$

(*b*) We replace the initial wavelength with $\lambda = 0.10$ nm.

$$\frac{\Delta\lambda}{\lambda} = \frac{h}{m_e c\lambda}(1-\cos\theta) = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)(1-\cos 180°)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)\left(0.10\times10^{-9}\,\text{m}\right)} = \boxed{0.049}$$

32. We find the change in wavelength for each scattering event using Eq. 37-6b, with a scattering angle of $\phi = 0.50°$. To calculate the total change in wavelength, we subtract the initial wavelength, obtained from the initial energy, from the final wavelength. We divide the change in wavelength by the wavelength change from each event to determine the number of scattering events.

$$\Delta\lambda = \frac{h}{m_e c}(1-\cos 0.5°) = \frac{\left(6.63\times10^{-34}\ \text{J}\cdot\text{s}\right)(1-\cos 0.5°)}{\left(9.11\times10^{-31}\ \text{kg}\right)\left(3.00\times10^{8}\ \text{m/s}\right)} = 9.24\times10^{-17}\,\text{m} = 9.24\times10^{-8}\,\text{nm}$$

$$\lambda_0 = \frac{hc}{E_0} = \frac{\left(6.63\times10^{-34}\ \text{J}\cdot\text{s}\right)\left(3.00\times10^{8}\ \text{m/s}\right)}{\left(1.0\times10^{6}\ \text{eV}\right)\left(1.60\times10^{-19}\ \text{J/eV}\right)} = 1.24\times10^{-12}\,\text{m} = 0.00124\,\text{nm}.$$

$$n = \frac{\lambda - \lambda_0}{\Delta\lambda} = \frac{(555\,\text{nm}) - (0.00124\,\text{nm})}{9.24\times10^{-8}\ \text{nm}} = \boxed{6\times10^{9}\,\text{events}}$$

33. (*a*) We use conservation of momentum to set the initial momentum of the photon equal to the sum of the final momentum of the photon and electron, where the momentum of the photon is given by Eq. 37-5 and the momentum of the electron is written in terms of the total energy (Eq. 36-13). We multiply this equation by the speed of light to simplify.

$$\frac{h}{\lambda} + 0 = -\left(\frac{h}{\lambda'}\right) + p_e \quad \rightarrow \quad \frac{hc}{\lambda} = -\left(\frac{hc}{\lambda'}\right) + \sqrt{E^2 - E_0^2}$$

Using conservation of energy we set the initial energy of the photon and rest energy of the electron equal to the sum of the final energy of the photon and the total energy of the electron.

$$\left(\frac{hc}{\lambda}\right) + E_0 = \left(\frac{hc}{\lambda'}\right) + E$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

By summing these two equations, we eliminate the final wavelength of the photon. We then solve the resulting equation for the kinetic energy of the electron, which is the total energy less the rest energy.

$$2\left(\frac{hc}{\lambda}\right)+E_0=\sqrt{E^2-{E_0}^2}+E \quad\rightarrow\quad \left[2\left(\frac{hc}{\lambda}\right)+E_0-E\right]^2=E^2-{E_0}^2$$

$$\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]^2-2E\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]+E^2=E^2-{E_0}^2 \quad\rightarrow\quad E=\frac{\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]^2+{E_0}^2}{2\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]}$$

$$K=E-E_0=\frac{\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]^2+{E_0}^2}{2\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]}-\frac{2\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]E_0}{2\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]}=\frac{2\left(\frac{hc}{\lambda}\right)^2}{\left[2\left(\frac{hc}{\lambda}\right)+E_0\right]}$$

$$=\frac{2\left(\frac{1240\text{ eV•nm}}{0.160\text{ nm}}\right)^2}{\left[2\left(\frac{1240\text{ eV•nm}}{0.160\text{ nm}}\right)+5.11\times10^5\text{eV}\right]}=\boxed{228\text{eV}}$$

(*b*) We solve the energy equation for the final wavelength.

$$\left(\frac{hc}{\lambda}\right)+E_0=\left(\frac{hc}{\lambda'}\right)+E$$

$$\lambda'=\frac{hc}{\left(\frac{hc}{\lambda}\right)+E_0-E}=\left[\frac{1}{\lambda}-\frac{K}{hc}\right]^{-1}=\left[\frac{1}{0.160\text{nm}}-\frac{228\text{eV}}{1240\text{eV•nm}}\right]^{-1}=\boxed{0.165\text{nm}}$$

34. First we use conservation of energy, where the energy of the photon is written in terms of the wavelength, to relate the initial and final energies. Solve this equation for the electron's final energy.

$$\left(\frac{hc}{\lambda}\right)+mc^2=\left(\frac{hc}{\lambda'}\right)+E \;\Rightarrow\; E=\left(\frac{hc}{\lambda}\right)-\left(\frac{hc}{\lambda'}\right)+mc^2$$

Next, we define the *x*-direction as the direction of the initial motion of the photon. We write equations for the conservation of momentum in the horizontal and vertical directions, where θ is the angle the photon makes with the initial direction of the photon and ϕ is the angle the electron makes.

$$p_x:\quad \frac{h}{\lambda}=p_e\cos\phi+\frac{h}{\lambda'}\cos\theta \qquad p_y:\quad 0=p_e\sin\phi+\frac{h}{\lambda'}\sin\theta$$

To eliminate the variable ϕ we solve the momentum equations for the electron's momentum, square the resulting equations and add the two equations together using the identity $\cos^2\theta+\sin^2\theta=1$.

$$\left(\frac{h}{\lambda}-\frac{h}{\lambda'}\cos\theta\right)^2=\left(p_e\cos\phi\right)^2 \qquad \left(\frac{h}{\lambda'}\sin\theta\right)^2=\left(p_e\sin\phi\right)^2$$

$$\left(p_e\cos\phi\right)^2+\left(p_e\sin\phi\right)^2=\left(\frac{h}{\lambda}-\frac{h}{\lambda'}\cos\theta\right)^2+\left(\frac{h}{\lambda'}\sin\theta\right)^2$$

$$p_e^2=\left(\frac{h}{\lambda}\right)^2-\frac{2h^2}{\lambda\lambda'}\cos\theta+\left(\frac{h}{\lambda'}\right)^2$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

We now apply the relativistic invariant equation, Eq. 36-13, to write the electron momentum in terms of the electron energy. Then using the electron energy obtained from the conservation of energy equation, we eliminate the electron energy and solve for the change in wavelength.

$$\left(\frac{h}{\lambda}\right)^2 - \frac{2h^2}{\lambda\lambda'}\cos\theta + \left(\frac{h}{\lambda'}\right)^2 = \frac{E^2 - m^2c^4}{c^2} = \left[\left(\frac{h}{\lambda}\right) - \left(\frac{h}{\lambda'}\right) + mc\right]^2 - m^2c^2$$

$$= \left(\frac{h}{\lambda}\right)^2 + \left(\frac{h}{\lambda'}\right)^2 + m^2c^2 + 2hmc\left(\frac{1}{\lambda} - \frac{1}{\lambda'}\right) - \frac{h^2}{\lambda\lambda'} - m^2c^2$$

$$-\frac{2h^2}{\lambda\lambda'}\cos\theta = 2hmc\left(\frac{1}{\lambda} - \frac{1}{\lambda'}\right) - \frac{h^2}{\lambda\lambda'}$$

$$-h\cos\theta = mc(\lambda' - \lambda) - h \quad \rightarrow \quad \boxed{\lambda' - \lambda = \frac{h}{mc}(1 - \cos\theta)}$$

35. The photon energy must be equal to the kinetic energy of the products plus the mass energy of the products. The mass of the positron is equal to the mass of the electron.

$$E_{\text{photon}} = K_{\text{products}} + m_{\text{products}}c^2 \quad \rightarrow$$

$$K_{\text{products}} = E_{\text{photon}} - m_{\text{products}}c^2 = E_{\text{photon}} - 2m_{\text{electron}}c^2 = 2.67\,\text{MeV} - 2(0.511\,\text{MeV}) = \boxed{1.65\,\text{MeV}}$$

36. The photon with the longest wavelength has the minimum energy in order to create the masses with no additional kinetic energy. Use Eq. 37-5.

$$\lambda_{\max} = \frac{hc}{E_{\min}} = \frac{hc}{2mc^2} = \frac{h}{2mc} = \frac{(6.63\times10^{-34}\,\text{J•s})}{2(1.67\times10^{-27}\,\text{kg})(3.00\times10^8\,\text{m/s})} = \boxed{6.62\times10^{-16}\,\text{m}}$$

This must take place in the presence of some other object in order for momentum to be conserved.

37. The minimum energy necessary is equal to the rest energy of the two muons.

$$E_{\min} = 2mc^2 = 2(207)(0.511\,\text{MeV}) = \boxed{212\,\text{MeV}}$$

The wavelength is given by Eq. 37-5.

$$\lambda = \frac{hc}{E} = \frac{(6.63\times10^{-34}\,\text{J•s})(3.00\times10^8\,\text{m/s})}{(1.60\times10^{-19}\,\text{J/eV})(212\times10^6\,\text{eV})} = \boxed{5.86\times10^{-15}\,\text{m}}$$

38. Since $v < 0.001c$, the total energy of the particles is essentially equal to their rest energy. Both particles have the same rest energy of 0.511 MeV. Since the total momentum is 0, each photon must have half the available energy and equal momenta.

$$E_{\text{photon}} = m_{\text{electron}}c^2 = \boxed{0.511\,\text{MeV}} \quad ; \quad p_{\text{photon}} = \frac{E_{\text{photon}}}{c} = \boxed{0.511\,\text{MeV}/c}$$

39. The energy of the photon is equal to the total energy of the two particles produced. Both particles have the same kinetic energy and the same mass.

$$E_{\text{photon}} = 2(K + mc^2) = 2(0.375\,\text{MeV} + 0.511\,\text{MeV}) = \boxed{1.772\,\text{MeV}}$$

The wavelength is found from Eq. 37-5.

$$\lambda = \frac{hc}{E} = \frac{(6.63\times10^{-34}\,\text{J•s})(3.00\times10^8\,\text{m/s})}{(1.60\times10^{-19}\,\text{J/eV})(1.772\times10^6\,\text{eV})} = \boxed{7.02\times10^{-13}\,\text{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

40. We find the wavelength from Eq. 37-7.

$$\lambda = \frac{h}{p} = \frac{h}{mv} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(0.23\text{kg}\right)\left(0.10\,\text{m/s}\right)} = \boxed{2.9\times10^{-32}\,\text{m}}$$

41. The neutron is not relativistic, so we can use $p = mv$. We also use Eq. 37-7.

$$\lambda = \frac{h}{p} = \frac{h}{mv} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(1.67\times10^{-27}\,\text{kg}\right)\left(8.5\times10^{4}\,\text{m/s}\right)} = \boxed{4.7\times10^{-12}\,\text{m}}$$

42. We assume the electron is non-relativistic, and check that with the final answer. We use Eq. 37-7.

$$\lambda = \frac{h}{p} = \frac{h}{mv} \quad\rightarrow\quad v = \frac{h}{m\lambda} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(9.11\times10^{-31}\text{kg}\right)\left(0.21\times10^{-9}\,\text{m}\right)} = 3.466\times10^{6}\,\text{m/s} = 0.01155c$$

Our use of classical expressions is justified. The kinetic energy is equal to the potential energy change.

$$eV = K = \tfrac{1}{2}mv^2 = \frac{\frac{1}{2}\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.466\times10^{6}\,\text{m/s}\right)^2}{\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 34.2\,\text{eV}$$

Thus the required potential difference is $\boxed{34\text{ V.}}$

43. The theoretical resolution limit is the wavelength of the electron. We find the wavelength from the momentum, and find the momentum from the kinetic energy and rest energy. We use the result from Problem 94. The kinetic energy of the electron is 85 keV.

$$\lambda = \frac{hc}{\sqrt{K^2 + 2mc^2K}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\sqrt{\left(85\times10^{3}\text{eV}\right)^2 + 2\left(0.511\times10^{6}\text{eV}\right)\left(85\times10^{3}\text{eV}\right)}}$$

$$= \boxed{4.1\times10^{-12}\,\text{m}}$$

44. We use the relativistic expression for momentum, Eq. 36-8.

$$p = \frac{mv}{\sqrt{1-v^2/c^2}} = \frac{mv}{\sqrt{1-v^2/c^2}} = \frac{h}{\lambda} \quad\rightarrow$$

$$\lambda = \frac{h\sqrt{1-v^2/c^2}}{mv} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\sqrt{1-\left(0.98\right)^2}}{\left(9.11\times10^{-31}\text{kg}\right)\left(0.98\right)\left(3.00\times10^{8}\,\text{m/s}\right)} = \boxed{4.9\times10^{-13}\,\text{m}}$$

45. Since the particles are not relativistic, we may use $K = p^2/2m$. We then form the ratio of the kinetic energies, using Eq. 37-7.

$$K = \frac{p^2}{2m} = \frac{h^2}{2m\lambda^2} \;;\; \frac{\lambda_\text{e}}{\lambda_\text{p}} = \frac{\frac{h^2}{2m_\text{e}\lambda^2}}{\frac{h^2}{2m_\text{p}\lambda^2}} = \frac{m_\text{p}}{m_\text{e}} = \frac{1.67\times10^{-27}\,\text{kg}}{9.11\times10^{-31}\,\text{kg}} = \boxed{1840}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

46. We assume the neutron is not relativistic. If the resulting velocity is small, our assumption will be valid. We use Eq. 37-7.

$$\lambda = \frac{h}{p} = \frac{h}{mv} \quad \rightarrow \quad v = \frac{h}{m\lambda} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(1.67\times10^{-27}\,\text{kg}\right)\left(0.3\times10^{-9}\,\text{m}\right)} = 1300\,\text{m/s} \approx \boxed{1000\,\text{m/s}}$$

This is not relativistic, so our assumption was valid.

47. (*a*) We find the momentum from Eq. 37-7.

$$p = \frac{h}{\lambda} = \frac{6.63\times10^{-34}\,\text{J•s}}{6.0\times10^{-10}\,\text{m}} = \boxed{1.1\times10^{-24}\,\text{kg•m/s}}$$

(*b*) We assume the speed is non-relativistic.

$$\lambda = \frac{h}{p} = \frac{h}{mv} \quad \rightarrow \quad v = \frac{h}{m\lambda} == \frac{6.63\times10^{-34}\,\text{J•s}}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(6.0\times10^{-10}\,\text{m}\right)} = \boxed{1.2\times10^{6}\,\text{m/s}}$$

Since $v/c = 4.04\times10^{-3}$, our assumption is valid.

(*c*) We calculate the kinetic energy classically.

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}\left(mc^2\right)\left(v/c\right)^2 = \tfrac{1}{2}\left(0.511\,\text{MeV}\right)\left(4.04\times10^{-3}\right)^2 = 4.17\times10^{-6}\,\text{MeV} = 4.17\,\text{eV}$$

This is the energy gained by an electron if accelerated through a potential difference of $\boxed{4.2\text{ V}}$.

48. Because all of the energies to be considered are much less than the rest energy of an electron, we can use non-relativistic relationships. We use Eq. 37-7 to calculate the wavelength.

$$K = \frac{p^2}{2m} \quad \rightarrow \quad p = \sqrt{2mK} \;\; ; \;\; \lambda = \frac{h}{p} = \frac{h}{\sqrt{2mK}}$$

(*a*) $$\lambda = \frac{h}{\sqrt{2mK}} = \frac{6.63\times10^{-34}\,\text{J•s}}{\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(20\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}} = 2.7\times10^{-10}\,\text{m} \approx \boxed{3\times10^{-10}\,\text{m}}$$

(*b*) $$\lambda = \frac{h}{\sqrt{2mK}} = \frac{6.63\times10^{-34}\,\text{J•s}}{\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(200\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}} = 8.7\times10^{-11}\,\text{m} \approx \boxed{9\times10^{-11}\,\text{m}}$$

(*c*) $$\lambda = \frac{h}{\sqrt{2mK}} = \frac{6.63\times10^{-34}\,\text{J•s}}{\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(2.0\times10^{3}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}} = \boxed{2.7\times10^{-11}\,\text{m}}$$

49. Since the particles are not relativistic, we may use $K = p^2/2m$. We then form the ratio of the wavelengths, using Eq. 37-7.

$$\lambda = \frac{h}{p} = \frac{h}{\sqrt{2mK}} \;\; ; \;\; \frac{\lambda_\text{p}}{\lambda_\text{e}} = \frac{\dfrac{h}{\sqrt{2m_\text{p}K}}}{\dfrac{h}{\sqrt{2m_\text{e}K}}} = \sqrt{\frac{m_\text{e}}{m_\text{p}}} < 1$$

Thus we see the proton has the shorter wavelength, since $m_\text{e} < m_\text{p}$.

50. The final kinetic energy of the electron is equal to the negative change in potential energy of the electron as it passes through the potential difference. We compare this energy to the rest energy of the electron to determine if the electron is relativistic.

$$K = -q\Delta V = \left(1\text{e}\right)\left(33\times10^{3}\,\text{V}\right) = 33\times10^{3}\,\text{eV}$$

Because this is greater than 1% of the electron rest energy, $\boxed{\text{the electron is relativistic}}$. We use Eq. 36-13 to determine the electron momentum and then Eq. 37-5 to determine the wavelength.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E^2 = \left[K + mc^2\right]^2 = p^2c^2 + m^2c^4 \;\Rightarrow p = \frac{\sqrt{K^2 + 2Kmc^2}}{c}$$

$$\lambda = \frac{h}{p} = \frac{hc}{\sqrt{K^2 + 2Kmc^2}} = \frac{1240\,\text{eV•nm}}{\sqrt{\left(33\times10^3\,\text{eV}\right)^2 + 2\left(33\times10^3\,\text{eV}\right)\left(511\times10^3\,\text{eV}\right)}} = 0.0066\,\text{nm}$$

Because λ « 5 cm, diffraction effects are negligible.

51. We will assume that the electrons are non-relativistic, and then examine the result in light of that assumption. The wavelength of the electron can be found from Eq. 34-2a. The speed can then be found from Eq. 37-7.

$$d\sin\theta = m_{\text{order}}\lambda \;\rightarrow\; \lambda = \frac{d\sin\theta}{m_{\text{order}}} \;;\; \lambda = \frac{h}{p} = \frac{h}{m_e v} \;\rightarrow$$

$$v = \frac{hm_{\text{order}}}{m_e d\sin\theta} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)(2)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.0\times10^{-6}\,\text{m}\right)(\sin 55°)} = \boxed{590\,\text{m/s}}$$

This is far from being relativistic, so our original assumption was fine.

52. We relate the kinetic energy to the momentum with a classical relationship, since the electrons are non-relativistic. We also use Eq. 37-7. We then assume that the kinetic energy was acquired by electrostatic potential energy.

$$K = \frac{p^2}{2m} = \frac{h^2}{2m\lambda^2} = eV \;\rightarrow$$

$$V = \frac{h^2}{2me\lambda^2} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)^2}{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(1.60\times10^{-19}\,\text{C}\right)\left(0.28\times10^{-9}\,\text{m}\right)^2} = \boxed{19\,\text{V}}$$

53. The kinetic energy is 3450 eV. That is small enough compared to the rest energy of the electron for the electron to be non-relativistic. We use Eq. 37-7.

$$\lambda = \frac{h}{p} = \frac{h}{\left(2mK\right)^{1/2}} = \frac{hc}{\left(2mc^2K\right)^{1/2}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^8\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\left[2\left(0.511\times10^6\,\text{eV}\right)\left(3450\ \text{eV}\right)\right]^{1/2}}$$

$$= 2.09\times10^{-11}\,\text{m} = \boxed{20.9\,\text{pm}}$$

54. The energy of a level is $E_n = -\dfrac{(13.6\ \text{eV})}{n^2}$.

(*a*) The transition from $n = 1$ to $n' = 3$ is an absorption, because the final state, $n' = 3$, has a higher energy. The photon energy is the difference between the energies of the two states.

$$hf = E_{n'} - E_n = -(13.6\ \text{eV})\left[\left(\frac{1}{3^2}\right) - \left(\frac{1}{1^2}\right)\right] = 12.1\ \text{eV}$$

(*b*) The transition from $n = 6$ to $n' = 2$ is an emission, because the initial state, $n' = 2$, has a higher energy. The photon energy is the difference between the energies of the two states.

$$hf = -\left(E_{n'} - E_n\right) = (13.6\ \text{eV})\left[\left(\frac{1}{2^2}\right) - \left(\frac{1}{6^2}\right)\right] = 3.0\ \text{eV}$$

(*c*) The transition from $n = 4$ to $n' = 5$ is an absorption, because the final state, $n' = 5$, has a higher energy. The photon energy is the difference between the energies of the two states.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$hf = E_{n'} - E_n = -(13.6\text{ eV})\left[\left(\frac{1}{5^2}\right) - \left(\frac{1}{4^2}\right)\right] = 0.31\text{ eV}$$

The photon for the transition from $\boxed{n = 1 \text{ to } n' = 3}$ has the largest energy.

55. To ionize the atom means removing the electron, or raising it to zero energy.

$$E_{\text{ionization}} = 0 - E_n = 0 - \frac{(-13.6\text{eV})}{n^2} = \frac{(13.6\text{eV})}{3^2} = \boxed{1.51\text{eV}}$$

56. We use the equation that appears above Eq. 37-15 in the text.

(*a*) The second Balmer line is the transition from $n = 4$ to $n = 2$.

$$\lambda = \frac{hc}{(E_4 - E_2)} = \frac{1240\text{eV}\bullet\text{nm}}{\left[-0.85\text{eV} - (-3.4\text{eV})\right]} = \boxed{490\text{nm}}$$

(*b*) The third Lyman line is the transition from $n = 4$ to $n = 1$.

$$\lambda = \frac{hc}{(E_4 - E_1)} = \frac{1240\text{eV}\bullet\text{nm}}{\left[-0.85\text{ eV} - (-13.6\text{ eV})\right]} = \boxed{97.3\text{nm}}$$

(*c*) The first Balmer line is the transition from $n = 3$ to $n = 2$.
For the jump from $n = 5$ to $n = 2$, we have

$$\lambda = \frac{hc}{(E_3 - E_2)} = \frac{1240\text{eV}\bullet\text{nm}}{\left[-1.5\text{ eV} - (-3.4\text{ eV})\right]} = \boxed{650\text{nm}}$$

57. Doubly ionized lithium is similar to hydrogen, except that there are three positive charges ($Z = 3$) in the nucleus. The square of the product of the positive and negative charges appears in the energy term for the energy levels. We can use the results for hydrogen, if we replace e^2 by Ze^2:

$$E_n = -\frac{Z^2(13.6\text{eV})}{n^2} = -\frac{3^2(13.6\text{eV})}{n^2} = -\frac{(122\text{eV})}{n^2}$$

$$E_{\text{ionization}} = 0 - E_1 = 0 - \left[-\frac{(122\text{eV})}{(1)^2}\right] = \boxed{122\text{eV}}$$

58. We evaluate the Rydberg constant using Eq. 37-8 and 37-15. We use hydrogen so $Z = 1$.

$$\frac{1}{\lambda} = R\left(\frac{1}{(n')^2} - \frac{1}{(n)^2}\right) = \frac{Z^2e^4m}{8\varepsilon_0^2h^3c}\left(\frac{1}{(n')^2} - \frac{1}{(n)^2}\right) \rightarrow$$

$$R = \frac{Z^2e^4m}{8\varepsilon_0^2h^3c} = \frac{(1)^2\left(1.602176\times10^{-19}\text{C}\right)^4\left(9.109382\times10^{-31}\text{kg}\right)}{8\left(8.854188\times10^{-12}\text{ C}^2/\text{N}\bullet\text{m}^2\right)^2\left(6.626069\times10^{-34}\text{J}\bullet\text{s}\right)^3\left(2.997925\times10^{8}\text{ m/s}\right)}$$

$$= 1.0974\times10^7\,\frac{\text{C}^4\bullet\text{kg}}{\frac{\text{C}^4}{\text{N}^2\bullet\text{m}^4}\text{J}^3\text{s}^3\text{ m/s}} = \boxed{1.0974\times10^7\text{ m}^{-1}}$$

59. The longest wavelength corresponds to the minimum energy, which is the ionization energy:

$$\lambda = \frac{hc}{E_{\text{ion}}} = \frac{\left(6.63\times10^{-34}\text{J}\bullet\text{s}\right)\left(3.00\times10^8\text{m/s}\right)}{\left(1.60\times10^{-19}\text{ J/eV}\right)(13.6\text{eV})} = 9.14\times10^{-8}\text{m} = \boxed{91.4\text{nm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

60. Singly ionized helium is like hydrogen, except that there are two positive charges ($Z = 2$) in the nucleus. The square of the product of the positive and negative charges appears in the energy term for the energy levels. We can use the results for hydrogen, if we replace e^2 by Ze^2.

$$E_n = -\frac{Z^2(13.6\text{ eV})}{n^2} = -\frac{2^2(13.6\text{ eV})}{n^2} = -\frac{(54.4\text{ eV})}{n^2}$$

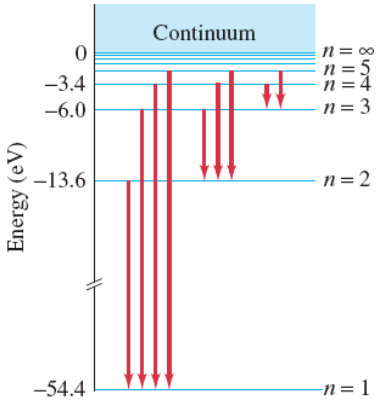
We find the energy of the photon from the $n = 5$ to $n = 2$ transition in singly-ionized helium.

$$\Delta E = E_5 - E_2 = -(54.4\text{ eV})\left[\left(\frac{1}{5^2}\right) - \left(\frac{1}{2^2}\right)\right] = 11.4\text{ eV}$$

Because this is NOT the energy difference between any two specific energy levels for hydrogen, the photon CANNOT be absorbed by hydrogen.

61. The energy of the photon is the sum of the ionization energy of 13.6 eV and the kinetic energy of 20.0eV. The wavelength is found from Eq. 37-3.

$$hf = \frac{hc}{\lambda} = E_{\text{total}} \quad \rightarrow \quad \lambda = \frac{hc}{E_{\text{total}}} = \frac{(6.63\times10^{-34}\text{ J•s})(3.00\times10^{8}\text{ m/s})}{(1.60\times10^{-19}\text{ J/eV})(33.6\text{ eV})} = 3.70\times10^{-8}\text{ m} = \boxed{37.0\text{ nm}}$$



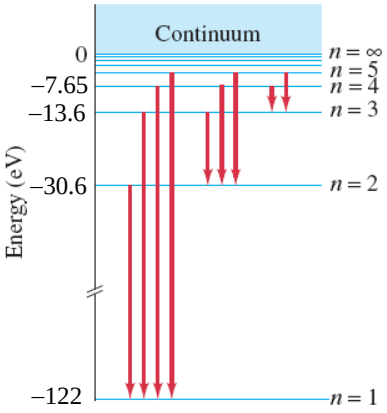
62. A collision is elastic if the kinetic energy before the collision is equal to the kinetic energy after the collision. If the hydrogen atom is in the ground state, then the smallest amount of energy it can absorb is the difference in the $n = 1$ and $n = 2$ levels. So as long as the kinetic energy of the incoming electron is less than that difference, the collision must be elastic.

$$K < E_2 - E_1 = \left(-\frac{13.6\text{eV}}{4}\right) - (-13.6\text{eV}) = \boxed{10.2\text{eV}}$$

63. Singly ionized helium is like hydrogen, except that there are two positive charges ($Z = 2$) in the nucleus. The square of the product of the positive and negative charges appears in the energy term for the energy levels. We can use the results for hydrogen, if we replace e^2 by Ze^2:

$$E_n = -\frac{Z^2(13.6\text{eV})}{n^2} = -\frac{2^2(13.6\text{eV})}{n^2} = -\frac{(54.4\text{eV})}{n^2}$$

$$E_1 = -54.5\text{eV},\ E_2 = -13.6\text{eV},\ E_3 = -6.0\text{eV},\ E_4 = -3.4\text{eV}$$



64. Doubly ionized lithium is like hydrogen, except that there are three positive charges ($Z = 3$) in the nucleus. The square of the product of the positive and negative charges appears in the energy term for the energy levels. We can use the results for hydrogen, if we replace e^2 by Ze^2:

$$E_n = -\frac{Z^2(13.6\text{eV})}{n^2} = -\frac{3^2(13.6\text{eV})}{n^2} = -\frac{(122.4\text{eV})}{n^2}$$

$$E_1 = -122\text{eV},\ E_2 = -30.6\text{eV},\ E_3 = -13.6\text{eV},$$

$$E_4 = -7.65\text{eV}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

65. The potential energy for the ground state is given by the charge of the electron times the electric potential caused by the proton.

$$U = (-e)V_{\text{proton}} = (-e)\frac{1}{4\pi\varepsilon_0}\frac{e}{r_1} = -\frac{\left(9.00\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(1.60\times10^{-19}\text{C}\right)^2\left(1\text{eV}/1.60\times10^{-19}\text{J}\right)}{\left(0.529\times10^{-10}\text{m}\right)}$$

$$= \boxed{-27.2\,\text{eV}}$$

The kinetic energy is the total energy minus the potential energy.

$$K = E_1 - U = -13.6\,\text{eV} - (-27.2\,\text{eV}) = \boxed{+13.6\,\text{eV}}$$

66. The value of *n* is found from $r_n = n^2 r_1$, and then find the energy from Eq. 37-14b.

$$r_n = n^2 r_1 \quad\rightarrow\quad n = \sqrt{\frac{r_n}{r_1}} = \sqrt{\frac{\frac{1}{2}\left(0.10\times10^{-3}\text{m}\right)}{0.529\times10^{-10}\text{m}}} = \boxed{972}$$

$$E = -\frac{(13.6\text{ eV})}{n^2} = -\frac{(13.6\text{ eV})}{972^2} = -\frac{(13.6\text{ eV})}{1375^2} = \boxed{-1.4\times10^{-5}\text{eV}}$$

67. The velocity is found from Eq. 37-10 evaluated for *n* = 1.

$$mvr_n = \frac{nh}{2\pi} \quad\rightarrow$$

$$v = \frac{h}{2\pi r_1 m_e} = \frac{\left(6.63\times10^{-34}\text{J}\cdot\text{s}\right)}{2\pi\left(0.529\times10^{-10}\text{m}\right)\left(9.11\times10^{-31}\text{kg}\right)} = 2.190\times10^{6}\text{ m/s} = \boxed{7.30\times10^{-3}c}$$

We see that $v \ll c$, and so yes, non-relativistic formulas are justified.
The relativistic factor is as follows.

$$\left[1-\left(\frac{v}{c}\right)^2\right]^{\frac{1}{2}} \approx 1 - \tfrac{1}{2}\left(\frac{v}{c}\right)^2 = 1 - \tfrac{1}{2}\left(\frac{2.190\times10^{6}\text{ m/s}}{3.00\times10^{8}\text{ m/s}}\right)^2 = \boxed{1 - 2.66\times10^{-5}} \approx 0.99997$$

We see that $\sqrt{1-v^2/c^2}$ is essentially 1, and so again the answer is yes, non-relativistic formulas are justified.

68. The angular momentum can be used to find the quantum number for the orbit, and then the energy can be found from the quantum number. Use Eqs. 37-10 and 37-14b.

$$L = n\frac{h}{2\pi} \quad\rightarrow\quad n = \frac{2\pi L}{h} = \frac{2\pi\left(5.273\times10^{-34}\text{ kg}\cdot\text{m}^2/\text{s}\right)}{\left(6.626\times10^{-34}\text{J}\cdot\text{s}\right)} = 5.000 \approx 5$$

$$E_n = -(13.6\text{eV})\frac{Z^2}{n^2} = -\frac{13.6\text{eV}}{25} = \boxed{0.544\,\text{eV}}$$

69. Hydrogen atoms start in the $n = 1$ orbit ("ground state"). Using Eq. 37-9 and Eq. 37-14b, we determine the orbit to which the atom is excited when it absorbs a photon of 12.75 Ev via collision with an electron. Then, using Eq. 37-15, we calculate all possible wavelengths that can be emitted as the electron cascades back to the ground state.

$$\Delta E = E_U - E_L \quad\rightarrow\quad E_U = -\frac{13.6\text{ eV}}{n^2} = E_L + \Delta E \quad\rightarrow$$

$$n = \sqrt{\frac{-13.6\text{ eV}}{E_L + \Delta E}} = \sqrt{\frac{-13.6\text{ eV}}{-13.6\text{ eV} + 12.75\text{ eV}}} = 4$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Starting with the electron in the $n=4$ orbit, the following transitions are possible: $n=4$ to $n=3$; $n=4$ to $n=2$; $n=4$ to $n=1$; $n=3$ to $n=2$; $n=3$ to $n=1$; $n=2$ to $n=1$.

$$\frac{1}{\lambda}=\left(1.097\times10^{7}\ \text{m}^{-1}\right)\left(\frac{1}{3^2}-\frac{1}{4^2}\right)=5.333\times10^{5}\ \text{m}^{-1}\Rightarrow\lambda=\boxed{1875\ \text{nm}}$$

$$\frac{1}{\lambda}=\left(1.097\times10^{7}\ \text{m}^{-1}\right)\left(\frac{1}{2^2}-\frac{1}{4^2}\right)=2.057\times10^{6}\ \text{m}^{-1}\Rightarrow\lambda=\boxed{486.2\ \text{nm}}$$

$$\frac{1}{\lambda}=\left(1.097\times10^{7}\ \text{m}^{-1}\right)\left(\frac{1}{1^2}-\frac{1}{4^2}\right)=1.028\times10^{7}\ \text{m}^{-1}\Rightarrow\lambda=\boxed{97.23\ \text{nm}}$$

$$\frac{1}{\lambda}=\left(1.097\times10^{7}\ \text{m}^{-1}\right)\left(\frac{1}{2^2}-\frac{1}{3^2}\right)=1.524\times10^{6}\ \text{m}^{-1}\Rightarrow\lambda=\boxed{656.3\ \text{nm}}$$

$$\frac{1}{\lambda}=\left(1.097\times10^{7}\ \text{m}^{-1}\right)\left(\frac{1}{1^2}-\frac{1}{3^2}\right)=9.751\times10^{6}\ \text{m}^{-1}\Rightarrow\lambda=\boxed{102.6\ \text{nm}}$$

$$\frac{1}{\lambda}=\left(1.097\times10^{7}\ \text{m}^{-1}\right)\left(\frac{1}{1^2}-\frac{1}{2^2}\right)=8.228\times10^{6}\ \text{m}^{-1}\Rightarrow\lambda=\boxed{121.5\ \text{nm}}$$

70. When we compare the gravitational and electric forces we see that we can use the same expression for the Bohr orbits, Eq. 37-11 and 37-14a, if we replace $Ze^2/4\pi\varepsilon_0$ with Gm_em_p.

$$r_1=\frac{h^2\varepsilon_0}{\pi m_eZe^2}=\frac{h^2}{4\pi^2m_e}\frac{4\pi\varepsilon_0}{Ze^2}\ \rightarrow$$

$$r_1=\frac{h^2}{4\pi^2Gm^2{}_em_p}=\frac{\left(6.626\times10^{-34}\,\text{J}\cdot\text{s}\right)^2}{4\pi^2\left(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(9.11\times10^{-31}\,\text{kg}\right)^2\left(1.67\times10^{-27}\,\text{kg}\right)}$$

$$=\boxed{1.20\times10^{29}\,\text{m}}$$

$$E_1=-\frac{Z^2e^4m_e}{8\varepsilon_0^2h^2}=-\left(\frac{Ze^2}{4\pi\varepsilon_0}\right)^2\frac{2\pi^2m_e}{h^2}\ \rightarrow\ E_1=-\frac{2\pi^2G^2m_e{}^3m_p{}^2}{h^2}$$

$$=-\frac{2\pi^2\left(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)^2\left(9.11\times10^{-31}\,\text{kg}\right)^3\left(1.67\times10^{-27}\,\text{kg}\right)^2}{\left(6.626\times10^{-34}\,\text{J}\cdot\text{s}\right)^2}=\boxed{-4.22\times10^{-97}\,\text{J}}$$

71. We know that the radii of the orbits are given by $r_n=n^2r_1$. Find the difference in radius for adjacent orbits.

$$\Delta r=r_n-r_{n-1}=n^2r_1-\left(n-1\right)^2r_1=n^2r_1-\left(n^2-2n+1\right)r_1=\left(2n-1\right)r_1$$

If $n\gg1$, we have $\Delta r\approx2nr_1=2n\dfrac{r_n}{n^2}=\dfrac{2r_n}{n}$.

In the classical limit, the separation of radii (and energies) should be very small. We see that letting $n\rightarrow\infty$ accomplishes this. If we substitute the expression for r_1 from Eq. 37-11, we have this.

$$\Delta r\approx2nr_1=\frac{2nh^2\varepsilon_0}{\pi me^2}$$

We see that $\Delta r\propto h^2$, and so letting $h\rightarrow0$ is equivalent to considering $n\rightarrow\infty$.

72. We calculate the energy from the light bulb that enters the eye by calculating the intensity of the light at a distance of 250 m by dividing the power in the visible spectrum by the area of a sphere of radius 250 m. We multiply the intensity of the light by the area of the pupil to determine the energy entering the eye per second. We divide this energy by the energy of a photon (Eq. 37-3) to calculate the number of photons entering the eye per second.

$$I = \frac{P}{4\pi \ell^2} \qquad P_e = I\left(\pi D^2/4\right) = \frac{P}{16}\left(\frac{D}{\ell}\right)^2$$

$$n = \frac{P_e}{hc/\lambda} = \frac{P\lambda}{16hc}\left(\frac{D}{\ell}\right)^2 = \frac{0.030(75\,\text{W})\left(550\times10^{-9}\,\text{m}\right)}{16\left(6.626\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}\left(\frac{4.0\times10^{-3}\,\text{m}}{250\,\text{m}}\right)^2$$

$$= \boxed{1.0\times10^{8}\,\text{photons/sec}}$$

73. To produce a photoelectron, the hydrogen atom must be ionized, so the minimum energy of the photon is 13.6 eV. We find the minimum frequency of the photon from Eq. 37-3.

$$E = hf \;\rightarrow\; f = \frac{E}{h} \;\rightarrow\; f_{\text{min}} = \frac{E_{\text{min}}}{h} = \frac{(13.6\text{ eV})\left(1.60\times10^{-19}\,\text{J/eV}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)} = \boxed{3.28\times10^{15}\,\text{Hz}}$$

74. From Section 35-10, the spacing between planes, d, for the first-order peaks is given by Eq. 35-20, $\lambda = 2d\sin\theta$. The wavelength of the electrons can be found from their kinetic energy. The electrons are not relativistic at the energy given.

$$K = \frac{p^2}{2m} = \frac{h^2}{2m\lambda^2} \;\rightarrow\; \lambda = \frac{h}{\sqrt{2mK}} = 2d\sin\theta \;\rightarrow$$

$$d = \frac{h}{2\sin\theta\sqrt{2mK}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{2(\sin 38°)\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)(125\,\text{eV})\left(1.60\times10^{-19}\,\text{J/eV}\right)}} = \boxed{8.9\times10^{-11}\,\text{m}}$$

75. The power rating is the amount of energy produced per second. If this is divided by the energy per photon, then the result is the number of photons produced per second.

$$E_{\text{photon}} = hf = \frac{hc}{\lambda} \;;\; \frac{P}{E_{\text{photon}}} = \frac{P\lambda}{hc} = \frac{(860\,\text{W})\left(12.2\times10^{-2}\,\text{m}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)} = \boxed{5.3\times10^{26}\,\text{photons/s}}$$

76. The intensity is the amount of energy per second per unit area reaching the Earth. If that intensity is divided by the energy per photon, the result will be the photons per second per unit area reaching the Earth. We use Eq. 37-3.

$$E_{\text{photon}} = hf = \frac{hc}{\lambda}$$

$$I_{\text{photons}} = \frac{I_{\text{sunlight}}}{E_{\text{photon}}} = \frac{I_{\text{sunlight}}\lambda}{hc} = \frac{\left(1350\,\text{W/m}^2\right)\left(550\times10^{-9}\,\text{m}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)} = \boxed{3.7\times10^{21}\,\text{photons/s•m}^2}$$

77. The impulse on the wall is due to the change in momentum of the photons. Each photon is absorbed, and so its entire momentum is transferred to the wall.

$$F_{\text{on wall}}\Delta t = \Delta p_{\text{wall}} = -\Delta p_{\text{photons}} = -\left(0 - np_{\text{photon}}\right) = np_{\text{photon}} = \frac{nh}{\lambda} \quad \rightarrow$$

$$\frac{n}{\Delta t} = \frac{F\lambda}{h} = \frac{\left(6.5\times10^{-9}\,\text{N}\right)\left(633\times10^{-9}\,\text{m}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)} = \boxed{6.2\times10^{18}\,\text{photons/s}}$$

78. We find the peak wavelength from Wien's law, Eq. 37-1.

$$\lambda_{\text{p}} = \frac{\left(2.90\times10^{-3}\,\text{m•K}\right)}{T} = \frac{\left(2.90\times10^{-3}\,\text{m•K}\right)}{\left(2.7\,\text{K}\right)} = 1.1\times10^{-3}\,\text{m} = \boxed{1.1\,\text{mm}}$$

79. The total energy of the two photons must equal the total energy (kinetic energy plus mass energy) of the two particles. The total momentum of the photons is 0, so the momentum of the particles must have been equal and opposite. Since both particles have the same mass and the same momentum, they each have the same kinetic energy.

$$E_{\text{photons}} = E_{\text{particles}} = 2\left(m_{\text{e}}c^2 + K\right) \quad \rightarrow$$

$$K = \tfrac{1}{2}E_{\text{photons}} - m_{\text{e}}c^2 = 0.755\,\text{MeV} - 0.511\,\text{MeV} = \boxed{0.244\,\text{MeV}}$$

80. We calculate the required momentum from de Broglie's relation, Eq. 37-7.

$$p = \frac{h}{\lambda} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(6.0\times10^{-12}\,\text{m}\right)} = 1.11\times10^{22}\ \text{kg•m/s}$$

(*a*) For the proton, we use the classical definition of momentum to determine the speed of the electron, and then the kinetic energy. We divide the kinetic energy by the charge of the proton to determine the required potential difference.

$$v = \frac{p}{m} = \frac{1.11\times10^{-22}\,\text{kg•m/s}}{1.67\times10^{-27}\,\text{kg}} = 6.65\times10^{4}\,\text{m/s} \ll c$$

$$V = \frac{K}{e} = \frac{mv^2}{2e} = \frac{\left(1.67\times10^{-27}\,\text{kg}\right)\left(6.65\times10^{4}\,\text{m/s}\right)^2}{2\left(1.60\times10^{-19}\,\text{C}\right)} = \boxed{23\,\text{V}}$$

(*b*) For the electron, if we divide the momentum by the electron mass we obtain a speed greater than 10% of the speed of light. Therefore, we must use the relativistic invariant equation to determine the energy of the electron. We then subtract the rest energy from the total energy to determine the kinetic energy of the electron. Finally, we divide the kinetic energy by the electron charge to calculate the potential difference.

$$E = \left[\left(pc\right)^2 + \left(m_0c^2\right)^2\right]^{\frac{1}{2}}$$

$$= \left[\left(1.11\times10^{-22}\,\text{kg•m/s}\right)^2\left(3.00\times10^{8}\,\text{m/s}\right)^2 + \left(9.11\times10^{-31}\,\text{kg}\right)^2\left(3.00\times10^{8}\,\text{m/s}\right)^4\right]^{\frac{1}{2}}$$

$$= 8.85\times10^{-14}\,\text{J}$$

$$K = E - m_0c^2 = 8.85\times10^{-14}\,\text{J} - \left(9.11\times10^{-31}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)^2 = 6.50\times10^{-15}\,\text{J}$$

$$V = \frac{K}{e} = \frac{6.50\times10^{-15}\,\text{J}}{1.60\times10^{-19}\,\text{C}} = \boxed{41\,\text{kV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

81. If we ignore the recoil motion, at the closest approach the kinetic energy of both particles is zero. The potential energy of the two charges must equal the initial kinetic energy of the α particle:

$$K_\alpha = U = \frac{1}{4\pi\varepsilon_0}\frac{(Z_\alpha e)(Z_{\text{Ag}} e)}{r_{\min}} \quad \rightarrow$$

$$r_{\min} = \frac{1}{4\pi\varepsilon_0}\frac{(Z_\alpha e)(Z_{\text{Ag}} e)}{K_\alpha} = \frac{(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(2)(47)(1.60\times10^{-19}\ \text{C})^2}{(4.8\ \text{MeV})(1.60\times10^{-13}\ \text{J/MeV})} = \boxed{2.8\times10^{-14}\ \text{m}}$$

82. The electrostatic potential energy is given by Eq. 23-5. The kinetic energy is given by the total energy, Eq. 37-14a, minus the potential energy. The Bohr radius is given by Eq. 37-11.

$$U = -eV = -\frac{1}{4\pi\varepsilon_0}\frac{Ze^2}{r_n} = -\frac{1}{4\pi\varepsilon_0}\frac{Ze^2\pi mZe^2}{n^2h^2\varepsilon_0} = -\frac{Z^2e^4m}{4n^2h^2\varepsilon_0^2}$$

$$K = E - U = -\frac{Z^2e^4m}{8\varepsilon_0^2h^2n^2} - \left(-\frac{Z^2e^4m}{4n^2h^2\varepsilon_0^2}\right) = \frac{Z^2e^4m}{8n^2h^2\varepsilon_0^2} \quad ; \quad \frac{|U|}{K} = \frac{\dfrac{Z^2e^4m}{4n^2h^2\varepsilon_0^2}}{\dfrac{Z^2e^4m}{8n^2h^2\varepsilon_0^2}} = \frac{Z^2e^4m}{4n^2h^2\varepsilon_0^2}\frac{8n^2h^2\varepsilon_0^2}{Z^2e^4m} = \boxed{2}$$

83. We calculate the ratio of the forces.

$$\frac{F_{\text{gravitational}}}{F_{\text{electric}}} = \frac{\left(\dfrac{Gm_em_p}{r^2}\right)}{\left(\dfrac{ke^2}{r^2}\right)} = \frac{Gm_em_p}{ke^2} = \frac{(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(9.11\times10^{-31}\ \text{kg})^2(1.67\times10^{-27}\ \text{kg})}{(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\ \text{C})^2}$$

$$= \boxed{4.4\times10^{-40}}$$

Yes, the gravitational force may be safely ignored.

84. The potential difference gives the electrons a kinetic energy of 12.3 eV, so it is possible to provide this much energy to the hydrogen atom through collisions. From the ground state, the maximum energy of the atom is $-13.6\ \text{eV} + 12.3\ \text{eV} = -1.3\ \text{eV}$. From the energy level diagram, Figure 37-26, we see that this means the atom could be excited to the $n = 3$ state, so the possible transitions when the atom returns to the ground state are $n = 3$ to $n = 2$, $n = 3$ to $n = 1$, and $n = 2$ to $n = 1$. We calculate the wavelengths from the equation above Eq. 37-15.

$$\lambda_{3\to2} = \frac{hc}{(E_3 - E_2)} = \frac{1240\ \text{eV}\cdot\text{nm}}{[-1.5\ \text{eV} - (-3.4\ \text{eV})]} = \boxed{650\ \text{nm}}$$

$$\lambda_{3\to1} = \frac{hc}{(E_3 - E_1)} = \frac{1240\ \text{eV}\cdot\text{nm}}{[-1.5\ \text{eV} - (-13.6\ \text{eV})]} = \boxed{102\ \text{nm}}$$

$$\lambda_{2\to1} = \frac{hc}{(E_2 - E_1)} = \frac{1240\ \text{eV}\cdot\text{nm}}{[-3.4\ \text{eV} - (-13.6\ \text{eV})]} = \boxed{122\ \text{nm}}$$

85. The stopping potential is the voltage that gives a potential energy change equal to the maximum kinetic energy. We use Eq. 37-4b to first find the work function, and then find the stopping potential for the higher wavelength.

$$K_{\max} = eV_0 = \frac{hc}{\lambda} - W_0 \quad \rightarrow \quad W_0 = \frac{hc}{\lambda_0} - eV_0$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$eV_1 = \frac{hc}{\lambda_1} - W_0 = \frac{hc}{\lambda_1} - \left(\frac{hc}{\lambda_0} - eV_0\right) = hc\left(\frac{1}{\lambda_1} - \frac{1}{\lambda_0}\right) + eV_0$$

$$= \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)}\left(\frac{1}{440\times10^{-9}\,\text{m}} - \frac{1}{380\times10^{-9}\,\text{m}}\right) + 2.70\,\text{eV} = 2.25\,\text{eV}$$

The potential difference needed to cancel an electron kinetic energy of 2.25 eV is $\boxed{2.25\text{ V.}}$

86. (*a*) The electron has a charge *e*, so the potential difference produces a kinetic energy of *eV*. The shortest wavelength photon is produced when all the kinetic energy is lost and a photon is emitted.

$$hf_{\max} = \frac{hc}{\lambda_0} = eV \quad\rightarrow\quad \lambda_0 = \boxed{\frac{hc}{eV}} \text{ which gives } \lambda_0 = \frac{hc}{eV}.$$

(*b*) $\lambda_0 = \dfrac{hc}{eV} = \dfrac{1240\,\text{eV•nm}}{33\times10^{3}\,\text{eV}} = \boxed{0.038\,\text{nm}}$

87. The average force on the sail is equal to the impulse on the sail divided by the time (Eq. 9-2). Since the photons bounce off the mirror the impulse is equal to twice the incident momentum. We use Eq. 37-5 to write the momentum of the photon in terms of the photon energy. The total photon energy is the intensity of the sunlight multiplied by the area of the sail

$$\overline{F} = \frac{\Delta p}{\Delta t} = \frac{2\left(E/c\right)}{\Delta t} = \frac{2\left(E/\Delta t\right)}{c} = \frac{2IA}{c} = \frac{2\left(1350\text{ W/m}^2\right)\left(1000\text{ m}\right)^2}{3.00\times10^{8}\text{ m/s}} = \boxed{9.0\text{ N}}$$

88. We first find the work function from the given data. A photon energy of 9.0 eV corresponds with a stopping potential of 4.0 V.

$$eV_0 = hf - W_0 \quad\rightarrow\quad W_0 = hf - eV_0 = 9.0\,\text{eV} - 4.0\,\text{eV} = 5.0\,\text{eV}$$

If the photons' wavelength is doubled, the energy is halved, from 9.0 eV to 4.5 eV. This is smaller than the work function, and so no current flows. Thus the maximum kinetic energy is $\boxed{0}$. Likewise, if the photon's wavelength is tripled, the energy is only 3.0 eV, which is still less than the work function, and so $\boxed{\text{no current flows}}$.

89. The electrons will be non-relativistic at that low energy. The maximum kinetic energy of the photoelectrons is given by Eq. 37-4b. The kinetic energy determines the momentum, and the momentum determines the wavelength of the emitted electrons. The shortest electron wavelength corresponds to the maximum kinetic energy.

$$K_{\text{electron}} = \frac{hc}{\lambda} - W_0 = \frac{p^2}{2m} = \frac{h^2}{2m\lambda_{\text{electron}}^2} \quad\rightarrow\quad \lambda_{\text{electron}} = \frac{h}{\sqrt{2m\left(\dfrac{hc}{\lambda} - W_0\right)}}$$

$$= \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(\dfrac{1240\,\text{eV•nm}}{360\,\text{nm}} - 2.4\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}} = \boxed{1.2\times10^{-9}\,\text{m}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

90. The wavelength is found from Eq. 35-13. The velocity of electrons with the same wavelength (and thus the same diffraction pattern) is found from their momentum, assuming they are not relativistic. We use Eq. 37-7 to relate the wavelength and momentum.

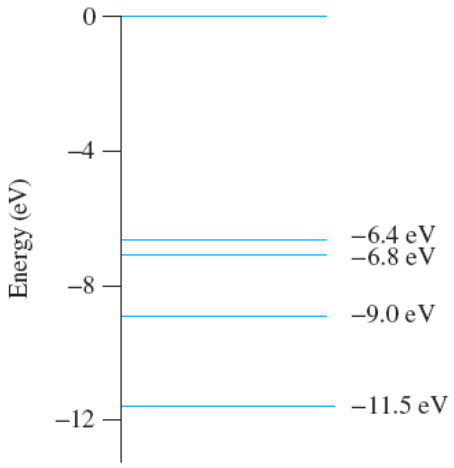
$$d\sin\theta = n\lambda \;\rightarrow\; \lambda = \frac{d\sin\theta}{n} = \frac{h}{p} = \frac{h}{mv} \;\rightarrow$$

$$v = \frac{hn}{md\sin\theta} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)(1)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(0.012\times10^{-3}\,\text{m}\right)(\sin 3.5°)} = \boxed{990\,\text{m/s}}$$

91. (*a*) See the adjacent figure.

(*b*) Absorption of a 5.1 eV photon represents a transition from the ground state to the state 5.1 eV above that, the third excited state. Possible photon emission energies are found by considering all the possible downward transitions that might occur as the electron makes its way back to the ground state.

$$-6.4\,\text{eV} - (-6.8\,\text{eV}) = \boxed{0.4\,\text{eV}}$$



$$-6.4\,\text{eV} - (-9.0\,\text{eV}) = \boxed{2.6\,\text{eV}}$$

$$-6.4\,\text{eV} - (-11.5\,\text{eV}) = \boxed{5.1\,\text{eV}}$$

$$-6.8\,\text{eV} - (-9.0\,\text{eV}) = \boxed{2.2\,\text{eV}}$$

$$-6.8\,\text{eV} - (-11.5\,\text{eV}) = \boxed{4.7\,\text{eV}}$$

$$-9.0\,\text{eV} - (-11.5\,\text{eV}) = \boxed{2.5\,\text{eV}}$$

92. (*a*) We use Eq. 37-4b to calculate the maximum kinetic energy of the electron and set this equal to the product of the stopping voltage and the electron charge.

$$K_{\max} = hf - W_0 = eV_0 \;\rightarrow\; V_0 = \frac{hf - W_0}{e} = \frac{hc/\lambda - W_0}{e}$$

$$V_0 = \frac{(1240\,\text{eV•nm})/(424\,\text{nm}) - 2.28\,\text{eV}}{\text{e}} = \boxed{0.65\,\text{V}}$$

(*b*) We calculate the speed from the non-relativistic kinetic energy equation and the maximum kinetic energy found in part (*a*).

$$K_{\max} = \tfrac{1}{2}mv_{\max}^2 \;\rightarrow\; v_{\max} = \sqrt{\frac{2K_{\max}}{m}} = \sqrt{\frac{2(0.65\,\text{eV})\left(1.60\times10^{-19}\,\text{J/eV}\right)}{9.11\times10^{-31}\,\text{kg}}} = \boxed{4.8\times10^{5}\,\text{m/s}}$$

(*c*) We use Eq. 37-7 to calculate the de Broglie wavelength.

$$\lambda = \frac{h}{p} = \frac{h}{mv} = \frac{6.63\times10^{-34}\,\text{J•s}}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(4.8\times10^{5}\,\text{m/s}\right)} = 1.52\times10^{-9}\,\text{m} = \boxed{1.5\,\text{nm}}$$

93. (*a*) We use Bohr's analysis of the hydrogen atom, where we replace the proton mass with Earth's mass, the electron mass with the Moon's mass, and the electrostatic force $F_e = \dfrac{ke^2}{r^2}$ with the gravitational force $F_g = \dfrac{Gm_E m_M}{r^2}$. To account for the change in force, we replace ke^2 with $Gm_E m_M$. With these replacements, we write expressions similar to Eq. 37-11 and Eq. 37-14a for the Bohr radius and energy.

$$r_n = \frac{h^2 n^2}{4\pi^2 mke^2} \quad \rightarrow$$

$$r_n = \frac{h^2 n^2}{4\pi^2 G m_M^2 m_E} = \frac{\left(6.626\times10^{-34}\,\text{J•s}\right)^2}{4\pi^2\left(6.67\times10^{-11}\,\text{N•m}^2/\text{kg}^2\right)\left(7.35\times10^{22}\,\text{kg}\right)^2\left(5.98\times10^{24}\,\text{kg}\right)} n^2$$

$$= \boxed{n^2\left(5.16\times10^{-129}\,\text{m}\right)}$$

$$E_n = -\frac{2\pi^2 e^4 mk^2}{n^2 h^2} \quad \rightarrow$$

$$E_n = -\frac{2\pi^2 G^2 m_E^2 m_M^3}{n^2 h^2} = -\frac{2\pi^2\left(6.67\times10^{-11}\,\text{N•m}^2/\text{kg}^2\right)^2\left(5.98\times10^{24}\,\text{kg}\right)^2\left(7.35\times10^{22}\,\text{kg}\right)^3}{n^2\left(6.626\times10^{-34}\,\text{J•s}\right)^2}$$

$$= \boxed{-\frac{2.84\times10^{165}\,\text{J}}{n^2}}$$

(*b*) We insert the known masses and Earth–Moon distance into the Bohr radius equation to determine the Bohr state.

$$n = \sqrt{\frac{4\pi^2 G m_M^2 m_E r_n}{h^2}}$$

$$= \sqrt{\frac{4\pi^2\left(6.67\times10^{-11}\ \text{Nm}^2/\text{kg}^2\right)\left(7.35\times10^{22}\ \text{kg}\right)^2\left(5.98\times10^{24}\ \text{kg}\right)\left(3.84\times10^{8}\ \text{m}\right)}{\left(6.626\times10^{-34}\ \text{Js}\right)^2}}$$

$$= 2.73\times10^{68}$$

Since $n \approx 10^{68}$, a value of $\Delta n = 1$ is negligible compared to *n*. Hence the quantization of energy and radius is not apparent.

94. We use Eqs. 36-13, 36-11, and 37-7 to derive the expression.

$$p^2c^2 + m^2c^4 = E^2 \ ;\ E = K + mc^2 \ \rightarrow\ p^2c^2 + m^2c^4 = \left(K + mc^2\right)^2 = K^2 + 2mc^2K + m^2c^4 \ \rightarrow$$

$$K^2 + 2mc^2K = p^2c^2 = \frac{h^2c^2}{\lambda^2} \ \rightarrow\ \lambda^2 = \frac{h^2c^2}{\left(K^2 + 2mc^2K\right)} \ \rightarrow\ \boxed{\lambda = \frac{hc}{\sqrt{K^2 + 2mc^2K}}}$$

95. As light leaves the flashlight it gains momentum. This change in momentum is given by Eq. 31-20. Dividing the change in momentum by the elapsed time gives the force the flashlight must apply to the light to produce this momentum. This is equal to the reaction force that light applies to the flashlight.

$$\frac{\Delta p}{\Delta t} = \frac{\Delta U}{c\Delta t} = \frac{P}{c} = \frac{3.0\,\text{W}}{3.00\times10^8\,\text{m/s}} = \boxed{1.0\times10^{-8}\,\text{N}}$$

96. (*a*) Since $f = c/\lambda$, the energy of each emitted photon is $E = hc/\lambda$. We insert the values for *h* and *c* and convert the resulting units to eV•nm.

$$E = \frac{hc}{\lambda} = \frac{\left(6.626\times10^{-34}\,\text{J•s}\right)\left(2.998\times10^8\,\text{m/s}\right)}{\lambda}\frac{\left(1\text{eV}/1.602\times10^{-19}\,\text{J}\right)}{\left(10^{-9}\,\text{m}/1\text{nm}\right)} = \boxed{\frac{1240\,\text{eV•nm}}{\lambda\,(\text{in nm})}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Insert 650 nm into the above equation.

$$E = \frac{1240\ \text{eV}\cdot\text{nm}}{650\ \text{nm}} = \boxed{1.9\ \text{eV}}$$

97. (*a*) We write the Planck time as $t_\text{P} = G^\alpha h^\beta c^\gamma$, and the units of t_P must be $[T]$.

$$t_\text{P} = G^\alpha h^\beta c^\gamma \quad \rightarrow \quad [T] = \left[\frac{L^3}{MT^2}\right]^\alpha \left[\frac{ML^2}{T}\right]^\beta \left[\frac{L}{T}\right]^\gamma = [L]^{3\alpha+2\beta+\gamma}[M]^{\beta-\alpha}[T]^{-2\alpha-\beta-\gamma}$$

There are no mass units in $[T]$, and so $\beta = \alpha$, and $[T] = [L]^{5\alpha+\gamma}[T]^{-3\alpha-\gamma}$. There are no length units in $[T]$, and so $\gamma = -5\alpha$ and $[T] = [T]^{-3\alpha+5\alpha} = [T]^{2\alpha}$. Thus $\alpha = \frac{1}{2} = \beta$ and $\gamma = -\frac{5}{2}$.

$$\boxed{t_\text{P} = G^{1/2}h^{1/2}c^{-5/2} = \sqrt{\frac{Gh}{c^5}}}$$

(*b*) $$t_\text{P} = \sqrt{\frac{Gh}{c^5}} = \sqrt{\frac{\left(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(6.63\times10^{-34}\ \text{J}\cdot\text{s}\right)}{\left(3.00\times10^8\ \text{m/s}\right)^5}} = \boxed{1.35\times10^{-43}\ \text{s}}$$

(*c*) We write the Planck length as $\lambda_\text{P} = G^\alpha h^\beta c^\gamma$, and the units of λ_P must be $[L]$.

$$\lambda_\text{P} = G^\alpha h^\beta c^\gamma \quad \rightarrow \quad [L] = \left[\frac{L^3}{MT^2}\right]^\alpha \left[\frac{ML^2}{T}\right]^\beta \left[\frac{L}{T}\right]^\gamma = [L]^{3\alpha+2\beta+\gamma}[M]^{\beta-\alpha}[T]^{-2\alpha-\beta-\gamma}$$

There are no mass units in $[L]$, and so $\beta = \alpha$, and $[L] = [L]^{5\alpha+\gamma}[T]^{-3\alpha-\gamma}$. There are no time units in $[L]$, and so $\gamma = -3\alpha$ and $[L] = [L]^{5\alpha-3\alpha} = [L]^{2\alpha}$. Thus $\alpha = \frac{1}{2} = \beta$ and $\gamma = -\frac{3}{2}$.

$$\boxed{t_\text{P} = G^{1/2}h^{1/2}c^{-3/2} = \sqrt{\frac{Gh}{c^3}}}$$

(*d*) $$\lambda_\text{P} = \sqrt{\frac{Gh}{c^3}} = \sqrt{\frac{\left(6.67\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(6.63\times10^{-34}\ \text{J}\cdot\text{s}\right)}{\left(3.00\times10^8\ \text{m/s}\right)^5}} = \boxed{4.05\times10^{-35}\ \text{m}}$$

98. For standing matter waves, there are nodes at the two walls. For the ground state (first harmonic), the wavelength is twice the distance between the walls, or $\ell = \frac{1}{2}\lambda$ (see Figure 15-26b). We use Eq. 37-7 to find the velocity and then the kinetic energy.

$$\ell = \tfrac{1}{2}\lambda \quad \rightarrow \quad \lambda = 2\ell \ ; \ p = \frac{h}{\lambda} = \frac{h}{2\ell} \ ; \ K = \frac{p^2}{2m} = \frac{1}{2m}\left(\frac{h}{2\ell}\right)^2 = \boxed{\frac{h^2}{8m\ell^2}}$$

For the second harmonic, the distance between the walls is a full wavelength, and so $\ell = \lambda$.

$$\ell = \lambda \quad \rightarrow \quad p = \frac{h}{\lambda} = \frac{h}{\ell} \ ; \ K = \frac{p^2}{2m} = \frac{1}{2m}\left(\frac{h}{\ell}\right)^2 = \boxed{\frac{h^2}{2m\ell^2}}$$

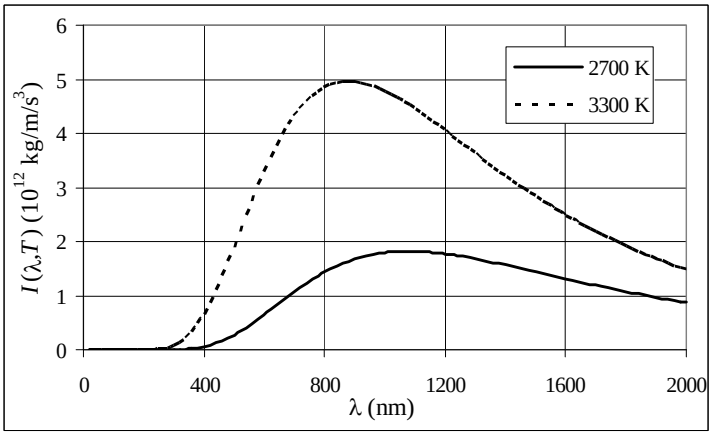
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

99. (*a*) Apply conservation of momentum before and after the emission of the photon to determine the recoil speed of the atom, where the momentum of the photon is given by Eq. 37-7.

$$0 = \frac{h}{\lambda} - mv \quad \rightarrow \quad v = \frac{h}{m\lambda} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{85\left(1.66\times10^{-27}\,\text{kg}\right)\left(780\times10^{-9}\,\text{m}\right)} = \boxed{6.0\times10^{-3}\,\text{m/s}}$$

(*b*) We solve Eq. 18-5 for the lowest achievable temperature, where the recoil speed is the rms speed of the rubidium gas.

$$v = \sqrt{\frac{3kT}{m}} \quad \rightarrow \quad T = \frac{mv^2}{3k} = \frac{85\left(1.66\times10^{-27}\,\text{kg}\right)\left(6.0\times10^{-3}\,\text{m/s}\right)^2}{3\left(1.38\times10^{-23}\,\text{J/K}\right)} = 1.2\times10^{-7}\,\text{K} = \boxed{0.12\ \mu\text{K}}$$



100. Each time the rubidium atom absorbs a photon its momentum decreases by the momentum of the photon. Dividing the initial momentum of the rubidium atom by the momentum of the photon, Eq. 37-7, gives the number of collisions necessary to stop the atom. Multiplying the number of collisions by the absorption time, 25 ns per absorption, provides the time to completely stop the atom.

$$n = \frac{mv}{h/\lambda} = \frac{mv\lambda}{h} = \frac{(8\,\text{u})\left(1.66\times10^{-27}\,\text{kg/u}\right)(290\,\text{m/s})\left(780\times10^{-9}\,\text{m}\right)}{6.63\times10^{-34}\,\text{J•s}} = 48{,}140$$

$$T = 48{,}140(25\,\text{ns}) = \boxed{1.2\,\text{ms}}$$

101. (*a*) See the adjacent graphs.

(*b*) To compare the intensities, the two graphs are numerically integrated from 400 nm to 760 nm, which is approximately the range of wavelengths for visible light. The result of those integrations is that the higher temperature bulb is about 4.8 times more intense than the lower temperature bulb.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH37.XLS," on tab "Problem 37.101."

102. Planck's radiation formula $I(\lambda,T)$ was calculated for a temperature of 6000 K, for wavelengths from 20 nm to 2000 nm. A plot of those calculations is in the spreadsheet for this problem. To estimate the % of emitted sunlight that is in the visible, this ratio was calculated by numeric integration. The details are in the spreadsheet.

$$\%\,\text{visible} = \frac{\int_{400\,\text{nm}}^{700\,\text{nm}} I(\lambda,T)\,d\lambda}{\int_{20\,\text{nm}}^{2000\,\text{nm}} I(\lambda,T)\,d\lambda} = \boxed{0.42}$$

So our estimate is that 42% of emitted sunlight is in the visible wavelengths. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH37.XLS," on tab "Problem 37.102."

103. (*a*) For the photoelectric effect experiment, Eq. 37-4b can be expressed as $K_{\max} = hf - W_0$. The maximum kinetic energy is equal to the potential energy associated with the stopping voltage, so $K_{\max} = eV_0$. We also have $f = c/\lambda$. Combine those relationships as follows.

$$K_{\max} = hf - W_0 \;\rightarrow\; eV_0 = \frac{hc}{\lambda} - W_0 \;\rightarrow\; V_0 = \frac{hc}{e}\frac{1}{\lambda} - \frac{W_0}{e}$$

A plot of V_0 vs. $\frac{1}{\lambda}$ should yield a straight line with a slope of $\boxed{\frac{hc}{e}}$ and a *y*-intercept of $\boxed{-\frac{W_0}{e}}$.

(*b*) The graph is shown, with a linear regression fit as given by Excel.

(*c*) The slope is $a = \frac{hc}{e} = 1.24\text{V}\bullet\mu\text{m}$, and the *y*-intercept is $b = -2.31\text{V}$.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH37.XLS," on tab "Problem 37.103."

(*d*) $b = -\frac{W_0}{e} = -2.31\text{V} \;\rightarrow\; W_0 = \boxed{2.31\text{eV}}$

(*e*) $h = \frac{ea}{c} = \frac{\left(1.60\times10^{-19}\text{C}\right)\left(1.24\times10^{-6}\text{V}\bullet\text{m}\right)}{3.00\times10^{8}\ \text{m/s}} = \boxed{6.61\times10^{-34}\text{J}\bullet\text{s}}$

CHAPTER 38: Quantum Mechanics

Responses to Questions

1. (*a*) A matter wave ψ does not need a medium as a wave on a string does. The square of the wave function for a matter wave ψ describes the probability of finding a particle within a certain spatial range, whereas the equation for a wave on a string describes the displacement of a piece of string from its equilibrium position.

   (*b*) An EM wave also does not need a medium. The equation for the EM wave describes the way in which the amplitudes of the electric and magnetic fields change as the wave passes a point in space. An EM wave represents a vector field and can be polarized. A matter wave is a scalar and cannot be polarized.

2. According to Bohr's theory, each electron in an atom travels in a circular orbit and has a precise position and momentum at any point in time. This view is inconsistent with the postulates of quantum mechanics and the uncertainty principle, which does not allow both the position and momentum to be known precisely. According to quantum mechanics, the "orbitals" of electrons do not have precise radii, but describe the probability of finding an electron in a given spatial range.

3. As mass increases, the uncertainty in the momentum of the object increases, and, from the Heisenberg uncertainty principle, the uncertainty in the position of the object decreases, making the future position of the object easier to predict.

4. Planck's constant is so small that on the scale of a baseball the uncertainties in position and momentum are negligible compared with the values of the position and momentum. If visible light is being used to observe the baseball, then the uncertainty in the baseball's position will be on the order of the wavelength of visible light. (See Section 38-3.) A baseball is very large compared to the wavelength of light, so any uncertainty in the position of the baseball will be much smaller than the extent of the object itself.

5. No. According to the uncertainty principle, if the needle were balanced the position of the center of mass would be known exactly, and there would have to be some uncertainty in its momentum. The center of mass of the needle could not have a zero momentum, and therefore would fall over. If the initial momentum of the center of mass of the needle were exactly zero, then there would be uncertainty in its position, and the needle could not be perfectly balanced (with the center of mass over the tip).

6. Yes, some of the air escapes the tire in the act of measuring the pressure and it is impossible to avoid this escape. The act of measuring the air pressure in a tire therefore actually changes the pressure, although not by much since very little air escapes compared to the total amount of air in the tire. This is similar to the uncertainty principle, in which one of the two factors limiting the precision of measurement is the interaction between the object begin observed, or measured, and the observing instrument.

7. Yes. In energy form, the uncertainty principle is $\Delta E \Delta t \geq h/2\pi$. For the ground state, Δt is very large, since electrons remain in that state for a very long time, so ΔE is very small and the energy of the state can be precisely known. For excited states, which can decay to the ground state, Δt is much smaller, and ΔE is corresponding larger. Therefore the energy of the state is less well known.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

8. If Planck's constant were much larger than it is, then the consequences of the uncertainty principle would be noticeable with macroscopic objects. For instance, attempts to determine a baseball's speed would mean that you could not find its position very accurately. Using a radar gun to find the speed of a pitcher's fastball would significantly change the actual course of the ball.

9. According to Newtonian mechanics, all objects have an exact position and momentum at a point in time. This information can be used to predict the future motion of an object. According to quantum mechanics, there is unavoidable uncertainty in the position and momentum of all objects. It is impossible to exactly determine both position and momentum at the same time, which introduces uncertainly into the prediction of the future motion of the object.

10. If you knew the position precisely, then you would know nothing about the momentum.

11. No. Some of the energy of the soup would be used to heat up the thermometer, so the temperature registered on the thermometer would be slightly less than the original temperature of the soup.

12. No. However, the greater the precision of the measurement of position, the greater the uncertainty in the measurement of the momentum of the object will be.

13. A particle in a box is confined to a region of space. Since the uncertainty in position is limited by the box, there must be some uncertainty in the particle's momentum, and the momentum cannot be zero. The zero point energy reflects the uncertainty in momentum.

14. Yes, the probability of finding the particle at these points is zero. It is possible for the particle to pass by these points. Since the particle is acting like a wave, these points correspond to the nodes in a standing wave pattern in the box.

15. For large values of n, the probability density varies rapidly between zero and the maximum value. It can be averaged easily to the classical result as n becomes large.

16. As n increases, the energy of the corresponding state increases, but $\Delta E/E$ approaches zero. For large n, the probability density varies rapidly between zero and the maximum value and is easily averaged to the classical result, which is a uniform probability density for all points in the well.

17. As the potential decreases, the wave function extends into the forbidden region as an exponential decay function. When the potential drops below the particle energy, the wave function outside the well changes from an exponential decay function to an oscillating function with a longer wavelength than the function within the well. When the potential is zero, the wavelengths of the wave function will be the same everywhere. The ground state energy of the particle in a well becomes the energy of the free particle.

18. The hydrogen atom will have a greater probability of tunneling through the barrier because it has a smaller mass and therefore a larger transmission coefficient. (See Equations 38-17a and 38-17b.)

Solutions to Problems

1. We find the wavelength of the neutron from Eq. 37-7. The peaks of the interference pattern are given by Eq. 34-2a and Figure 34-10. For small angles, we have $\sin\theta = \tan\theta$.

$$\lambda = \frac{h}{p} = \frac{h}{\sqrt{2m_0K}} \;;\; d\sin\theta = m\lambda,\ m = 1,2,\ldots \;;\; y = \ell\tan\theta$$

$$\sin\theta = \tan\theta \;\rightarrow\; \frac{m\lambda}{d} = \frac{y}{\ell} \;\rightarrow\; y = \frac{m\lambda\ell}{d},\ m = 1,2,\ldots \;\rightarrow$$

$$\Delta y = \frac{\lambda\ell}{d} = \frac{h\ell}{d\sqrt{2m_0K}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(1.0\,\text{m}\right)}{\left(6.0\times10^{-4}\,\text{m}\right)\sqrt{2\left(1.67\times10^{-27}\,\text{kg}\right)\left(0.030\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}}$$

$$= \boxed{2.8\times10^{-7}\,\text{m}}$$

2. We find the wavelength of a pellet from Eq. 37-7. The half-angle for the central circle of the diffraction pattern is given in Section 35-4 as $\sin\theta = \dfrac{1.22\lambda}{D}$, where D is the diameter of the opening. Assuming the angle is small, the diameter of the spread of the bullet beam is $d = 2\ell\tan\theta = 2\ell\sin\theta$.

$$\lambda = \frac{h}{p} = \frac{h}{mv} \;;\; d = 2\ell\tan\theta = 2\ell\sin\theta = 2\ell\frac{1.22\lambda}{D} = 2\ell\frac{1.22h}{Dmv} \;\rightarrow$$

$$\ell = \frac{Dmvd}{2.44h} = \frac{\left(3.0\times10^{-3}\,\text{m}\right)\left(3.0\times10^{-3}\,\text{kg}\right)\left(150\,\text{m/s}\right)\left(0.010\,\text{m}\right)}{2.44\left(6.63\times10^{-34}\,\text{J•s}\right)} = \boxed{8.3\times10^{27}\,\text{m}}$$

This is almost 10^{12} light years.

3. The uncertainty in the velocity is given. Use Eq. 38-1 to find the uncertainty in the position.

$$\Delta x \geq \frac{\hbar}{\Delta p} = \frac{\hbar}{m\Delta v} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{\left(1.67\times10^{-27}\,\text{kg}\right)\left(1200\,\text{m/s}\right)} = \boxed{5.3\times10^{-11}\,\text{m}}$$

4. The minimum uncertainty in the energy is found from Eq. 38-2.

$$\Delta E \geq \frac{\hbar}{\Delta t} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{\left(1\times10^{-8}\,\text{s}\right)} = 1.055\times10^{-26}\,\text{J}\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = 6.59\times10^{-8}\,\text{eV} \approx \boxed{10^{-7}\,\text{eV}}$$

5. The uncertainty in position is given. Use Eq. 38-1 to find the uncertainty in the momentum.

$$\Delta p = m\Delta v \geq \frac{\hbar}{\Delta x} \;\rightarrow\; \Delta v \geq \frac{\hbar}{m\Delta x} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{\left(9.11\times10^{-31}\,\text{kg}\right)\left(2.6\times10^{-8}\,\text{m}\right)} = 4454\,\text{m/s} \approx \boxed{4500\,\text{m/s}}$$

6. The uncertainty in the energy is found from the lifetime and the uncertainty principle.

$$\Delta E = \frac{\hbar}{\Delta t} = \frac{h}{2\pi\Delta t} \;;\; E = h\nu = \frac{hc}{\lambda}$$

$$\frac{\Delta E}{E} = \frac{\dfrac{h}{2\pi\Delta t}}{\dfrac{hc}{\lambda}} = \frac{\lambda}{2\pi c\Delta t} = \frac{500\times10^{-9}\,\text{m}}{2\pi\left(3.00\times10^{8}\,\text{m/s}\right)\left(10\times10^{-9}\,\text{s}\right)} = 2.65\times10^{-8} \approx \boxed{3\times10^{-8}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E = \frac{hc}{\lambda} \;\rightarrow\; dE = -\frac{hc}{\lambda^2}d\lambda \;\rightarrow\; \Delta E \approx -\frac{hc}{\lambda^2}\Delta\lambda = -\frac{E}{\lambda}\Delta\lambda \;\rightarrow\; \frac{\Delta E}{E} = -\frac{\Delta\lambda}{\lambda}$$

The wavelength uncertainty is the absolute value of this expression, and so $\frac{\Delta\lambda}{\lambda} = \boxed{3\times10^{-8}}$

7. The uncertainty in the energy is found from the lifetime and the uncertainty principle.

$$\Delta E = \frac{\hbar}{\Delta t} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{\left(12\times10^{-6}\,\text{s}\right)}\left(\frac{1\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = 5.49\times10^{-11}\,\text{eV}$$

$$\frac{\Delta E}{E} = \frac{5.49\times10^{-11}\,\text{eV}}{5500\,\text{eV}} = \boxed{1.0\times10^{-14}}$$

8. (*a*) We find the wavelength from Eq. 37-7.

$$\lambda = \frac{h}{p} = \frac{h}{mv} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{(0.012\,\text{kg})(180\,\text{m/s})} = \boxed{3.1\times10^{-34}\,\text{m}}$$

(*b*) Use Eq. 38-1 to find the uncertainty in momentum

$$\Delta p_y \geq \frac{\hbar}{\Delta y} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{(0.0065\,\text{m})} = \boxed{1.6\times10^{-32}\,\text{kg•m/s}}$$

9. The uncertainty in the position is found from the uncertainty in the velocity and Eq. 38-1.

$$\Delta x_{\text{electron}} \geq \frac{\hbar}{\Delta p} = \frac{\hbar}{m\Delta v} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{\left(9.11\times10^{-31}\,\text{kg}\right)(95\,\text{m/s})\left(8.5\times10^{-4}\right)} = \boxed{1.4\times10^{-3}\,\text{m}}$$

$$\Delta x_{\text{baseball}} \geq \frac{\hbar}{\Delta p} = \frac{\hbar}{m\Delta v} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{(0.14\,\text{kg})(95\,\text{m/s})\left(8.5\times10^{-4}\right)} = \boxed{9.3\times10^{-33}\,\text{m}}$$

$$\frac{\Delta x_{\text{electron}}}{\Delta x_{\text{baseball}}} = \frac{m_{\text{baseball}}}{m_{\text{electron}}} = \frac{(0.14\,\text{kg})}{\left(9.11\times10^{-31}\,\text{kg}\right)} = 1.5\times10^{29}$$

The uncertainty for the electron is greater by a factor of 1.5×10^{29}.

10. We find the uncertainty in the energy of the muon from Eq. 38-2, and then find the uncertainty in the mass.

$$\Delta E \geq \frac{\hbar}{\Delta t} \;;\; \Delta E = (\Delta m)c^2 \;\rightarrow$$

$$\Delta m \geq \frac{\hbar}{c^2\Delta t} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{c^2\left(2.20\times10^{-6}\,\text{s}\right)} = \left(4.7955\times10^{-29}\,\frac{\text{J}}{c^2}\right)\left(\frac{1\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = \boxed{3.00\times10^{-10}\,\text{eV}/c^2}$$

11. We find the uncertainty in the energy of the free neutron from Eq. 38-2, and then the mass uncertainty from Eq. 36-12. We assume the lifetime of the neutron is good to two significant figures. The current experimental lifetime of the neutron is 886 seconds, so the 900 second value is certainly good to at least 2 significant figures.

$$\Delta E \geq \frac{\hbar}{\Delta t} \;;\; \Delta E = (\Delta m)c^2 \;\rightarrow\; \Delta m \geq \frac{\hbar}{c^2\Delta t} = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)}{\left(3.00\times10^{8}\,\text{m/s}\right)^2(900\,\text{s})} = \boxed{1.3\times10^{-54}\,\text{kg}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

12. Use the radius as the uncertainty in position for the electron. We find the uncertainty in the momentum from Eq. 38-1, and then find the energy associated with that momentum from Eq. 36-13.

$$\Delta p \geq \frac{\hbar}{\Delta x} = \frac{\left(1.055\times10^{-34}\ \text{J•s}\right)}{\left(1.0\times10^{-15}\ \text{m}\right)} = 1.055\times10^{-19}\ \text{kg•m/s}.$$

If we assume that the lowest value for the momentum is the least uncertainty, we can estimate the lowest possible energy.

$$E = \left(p^2c^2 + m_0{}^2c^4\right)^{1/2} = \left[\left(\Delta p\right)^2 c^2 + m_0{}^2c^4\right]^{1/2}$$

$$= \left[\left(1.055\times10^{-19}\ \text{kg•m/s}\right)^2\left(3.00\times10^8\ \text{m/s}\right)^2 + \left(9.11\times10^{-31}\ \text{kg}\right)^2\left(3.00\times10^8\ \text{m/s}\right)^4\right]^{1/2}$$

$$= 3.175\times10^{-11}\ \text{J}\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right) \approx \boxed{200\,\text{MeV}}$$

13. (*a*) The minimum uncertainty in the energy is found from Eq. 38-2.

$$\Delta E \geq \frac{\hbar}{\Delta t} = \frac{\left(1.055\times10^{-34}\ \text{J•s}\right)}{\left(1\times10^{-8}\,\text{s}\right)} = 1.055\times10^{-26}\,\text{J}\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = 6.59\times10^{-8}\,\text{eV} \approx \boxed{10^{-7}\,\text{eV}}$$

(*b*) The transition energy can be found from Eq. 37-14b. $Z = 1$ for hydrogen.

$$E_n = -\left(13.6\,\text{eV}\right)\frac{Z^2}{n^2} \quad\rightarrow\quad E_2 - E_1 = \left[-\left(13.6\,\text{eV}\right)\frac{1^2}{2^2}\right] - \left[-\left(13.6\,\text{eV}\right)\frac{1^2}{1^2}\right] = 10.2\,\text{eV}$$

$$\frac{\Delta E}{E_2 - E_1} = \frac{6.59\times10^{-8}\,\text{eV}}{10.2\,\text{eV}} = 6.46\times10^{-9} \approx \boxed{10^{-8}}$$

(*c*) The wavelength is given by Eq. 37-3.

$$E = h\nu = \frac{hc}{\lambda} \quad\rightarrow$$

$$\lambda = \frac{hc}{E} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^8\ \text{m/s}\right)}{\left(10.2\,\text{eV}\right)\left(\dfrac{1.60\times10^{-19}\,\text{J}}{\text{eV}}\right)} = 1.22\times10^{-7}\,\text{m} = 122\,\text{nm} \approx \boxed{100\,\text{nm}}$$

Take the derivative of the above relationship to find $\Delta\lambda$.

$$\lambda = \frac{hc}{E} \quad\rightarrow\quad d\lambda = -\frac{hc}{E^2}dE \quad\rightarrow\quad \Delta\lambda = -\frac{hc}{E^2}\Delta E = -\lambda\frac{\Delta E}{E} \quad\rightarrow$$

$$\left|\Delta\lambda\right| = \lambda\frac{\Delta E}{E} = \left(122\,\text{nm}\right)\left(6.46\times10^{-9}\right) = 7.88\times10^{-7}\,\text{nm} \approx \boxed{10^{-6}\text{nm}}$$

14. We assume the electron is non-relativistic. The momentum is calculated from the kinetic energy, and the position uncertainty from the momentum uncertainty, Eq. 38-1. Since the kinetic energy is known to 1.00%, we have $\Delta K/K = 1.00\times10^{-2}$.

$$p = \sqrt{2mK}\ ;\ \frac{dp}{dK} = \sqrt{2m}\left(\frac{1}{2\sqrt{K}}\right) = \frac{\sqrt{2mK}}{2K} \quad\rightarrow\quad \Delta p \approx \frac{\sqrt{2mK}}{2K}\Delta K = \tfrac{1}{2}\sqrt{2mK}\,\frac{\Delta K}{K}$$

$$\Delta x \geq \frac{\hbar}{\Delta p} = \frac{\hbar}{\tfrac{1}{2}\sqrt{2mK}\,\dfrac{\Delta K}{K}} = \frac{\left(1.055\times10^{-34}\ \text{J•s}\right)}{\tfrac{1}{2}\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.50\,\text{keV}\right)\left(1.60\times10^{-16}\,\text{J/keV}\right)}\left(1.00\times10^{-2}\right)}$$

$$= \boxed{6.61\times10^{-10}\,\text{m}}$$

15. Let us assume that the electron has an initial x momentum p_x, so that it has a wavelength of $\lambda = h/p_x$. The maxima of the double-slit interference pattern occur at locations satisfying Eq. 34-2a, $d\sin\theta = m\lambda$, $m = 0,1,2,\cdots$. If the angles are small, then we replace $\sin\theta$ by θ, and so the maxima are given by $\theta = m\lambda/d$. The angular separation of the maxima is then $\Delta\theta = \lambda/d$, and the angular separation between a maximum and the adjacent minimum is $\Delta\theta = \lambda/2d$. The separation of a maximum and the adjacent minimum on the screen is then $\Delta y_{\text{screen}} = \lambda\ell/2d$, where ℓ is the distance from the slits to the detection screen. This means that many electrons hit the screen at a maximum position, and very few electrons hit the screen a distance $\lambda\ell/2d$ to either side of that maximum position.

If the particular slit that an electron passes through is known, then Δy for the electrons at the location of the slits is $d/2$. The uncertainty principle says $\Delta p_y \geq \dfrac{\hbar}{\Delta y_{\text{slits}}} = \dfrac{\hbar}{\frac{1}{2}d} = \dfrac{h}{\pi d}$. We assume that p_y for the electron must be at least that big. Because of this uncertainty in y momentum, the electron has an uncertainty in its location on the screen, as $\dfrac{\Delta y_{\text{screen}}}{\ell} = \dfrac{\Delta p_y}{p_x} \rightarrow \Delta y_{\text{screen}} = \ell\dfrac{\frac{h}{\pi d}}{\frac{h}{\lambda}} = \dfrac{\lambda\ell}{\pi d}$.

Since this is about the same size as the separation between maxima and minima, the interference pattern will be "destroyed." The electrons will not be grouped near the maxima locations. They will instead be "spread out" on the screen, and no interference pattern will be visible.

16. We are given that $\Psi_1(x,t)$ and $\Psi_2(x,t)$ are solutions to the Schrödinger equation. Substitute the function $A\Psi_1(x,t) + B\Psi_2(x,t)$ into the Schrödinger equation.

$$-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2}\left[A\Psi_1 + B\Psi_2\right] + U(x)\left[A\Psi_1 + B\Psi_2\right] = -\frac{\hbar^2}{2m}\frac{\partial^2\left(A\Psi_1\right)}{\partial x^2} - \frac{\hbar^2}{2m}\frac{\partial^2\left(B\Psi_2\right)}{\partial x^2} + U(x)A\Psi_1 + U(x)B\Psi_2$$

$$= -A\frac{\hbar^2}{2m}\frac{\partial^2\Psi_1}{\partial x^2} - B\frac{\hbar^2}{2m}\frac{\partial^2\Psi_2}{\partial x^2} + AU(x)\Psi_1 + BU(x)\Psi_2$$

$$= A\left(-\frac{\hbar^2}{2m}\frac{\partial^2\Psi_1}{\partial x^2} + U(x)\Psi_1\right) + B\left(-\frac{\hbar^2}{2m}\frac{\partial^2\Psi_2}{\partial x^2} + U(x)\Psi_2\right)$$

$$= A\left(i\hbar\frac{\partial\Psi_1}{\partial t}\right) + B\left(i\hbar\frac{\partial\Psi_2}{\partial t}\right) = i\hbar\frac{\partial}{\partial t}\left[A\Psi_1 + B\Psi_2\right]$$

So, since $-\dfrac{\hbar^2}{2m}\dfrac{\partial^2}{\partial x^2}\left[A\Psi_1 + B\Psi_2\right] + U(x)\left[A\Psi_1 + B\Psi_2\right] = i\hbar\dfrac{\partial}{\partial t}\left[A\Psi_1 + B\Psi_2\right]$, the combination $A\Psi_1(x,t) + B\Psi_2(x,t)$ is also a solution to the time-dependent Schrödinger equation.

17. (*a*) Substitute $\Psi(x,t) = Ae^{i(kx-\omega t)}$ into both sides of the time-dependent Schrödinger equation, Eq. 38-7, and compare the functional form of the results.

$$-\frac{\hbar^2}{2m}\frac{\partial^2\Psi}{\partial x^2} + U_0\Psi = -\frac{\hbar^2}{2m}\frac{\partial^2 Ae^{i(kx-\omega t)}}{\partial x^2} + U_0 Ae^{i(kx-\omega t)} = \left(\frac{\hbar^2k^2}{2m} + U_0\right)Ae^{i(kx-\omega t)}$$

$$i\hbar\frac{\partial\Psi}{\partial t} = i\hbar\frac{\partial Ae^{i(kx-\omega t)}}{\partial t} = \hbar\omega Ae^{i(kx-\omega t)}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Both sides of the equation give a result of $(\text{constant})Ae^{i(kx-\omega t)}$, and so t $\Psi(x,t) = Ae^{i(kx-\omega t)}$ is a valid solution, if the constants are equal.

Now repeat the process for $\Psi(x,t) = A\cos(kx-\omega t)$.

$$-\frac{\hbar^2}{2m}\frac{\partial^2\Psi}{\partial x^2} + U_0\Psi = -\frac{\hbar^2}{2m}\frac{\partial^2 A\cos(kx-\omega t)}{\partial x^2} + U_0 A\cos(kx-\omega t)$$
$$= \left(\frac{\hbar^2 k^2}{2m} + U_0\right)A\cos(kx-\omega t)$$

$$i\hbar\frac{\partial\Psi}{\partial t} = i\hbar\frac{\partial A\cos(kx-\omega t)}{\partial t} = i\hbar\omega A\sin(kx-\omega t)$$

Because $\cos(kx-\omega t) \neq \sin(kx-\omega t)$ for arbitrary values of *x* and *t*, $\Psi(x,t) = A\cos(kx-\omega t)$ is NOT a valid solution.

Now repeat the process for $\Psi(x,t) = A\sin(kx-\omega t)$.

$$-\frac{\hbar^2}{2m}\frac{\partial^2\Psi}{\partial x^2} + U_0\Psi = -\frac{\hbar^2}{2m}\frac{\partial^2 A\sin(kx-\omega t)}{\partial x^2} + U_0 A\sin(kx-\omega t)$$
$$= \left(\frac{\hbar^2 k^2}{2m} + U_0\right)A\sin(kx-\omega t)$$

$$i\hbar\frac{\partial\Psi}{\partial t} = i\hbar\frac{\partial A\sin(kx-\omega t)}{\partial t} = -i\hbar\omega A\cos(kx-\omega t)$$

Because $\cos(kx-\omega t) \neq \sin(kx-\omega t)$ for arbitrary values of *x* and *t*, $\Psi(x,t) = A\sin(kx-\omega t)$ is NOT a valid solution.

(*b*) Conservation of energy gives the following result.

$$E = K + U = \frac{p^2}{2m} + U_0 \;;\; p = \frac{h}{\lambda} = \frac{hk}{2\pi} = \hbar k \;\rightarrow\; \hbar\omega = \frac{\hbar^2 k^2}{2m} + U_0$$

We equate the two results from the valid solution.

$$\left(\frac{\hbar^2 k^2}{2m} + U_0\right)Ae^{i(kx-\omega t)} = \hbar\omega Ae^{i(kx-\omega t)} \;\rightarrow\; \frac{\hbar^2 k^2}{2m} + U_0 = \hbar\omega$$

The expressions are the same.

18. The wave function is given in the form $\psi(x) = A\sin kx$.

(*a*) $\lambda = \dfrac{2\pi}{k} = \dfrac{2\pi}{2.0\times10^{10}\,\text{m}^{-1}} = 3.142\times10^{-10}\,\text{m} \approx \boxed{3.1\times10^{-10}\,\text{m}}$

(*b*) $p = \dfrac{h}{\lambda} = \dfrac{6.63\times10^{-34}\,\text{J•s}}{3.142\times10^{-10}\,\text{m}} = 2.110\times10^{-24}\,\text{kg•m/s} \approx \boxed{2.1\times10^{-24}\,\text{kg•m/s}}$

(*c*) $v = \dfrac{p}{m} = \dfrac{2.110\times10^{-24}\,\text{kg•m/s}}{9.11\times10^{-31}\,\text{kg}} = \boxed{2.3\times10^{6}\,\text{m/s}}$

(*d*) $K = \dfrac{p^2}{2m} = \dfrac{\left(2.110\times10^{-24}\,\text{kg•m/s}\right)^2}{2\left(9.11\times10^{-31}\,\text{kg}\right)}\dfrac{1}{\left(1.60\times10^{-19}\,\text{J/eV}\right)} = \boxed{15\,\text{eV}}$

19. The general expression for the wave function of a free particle is given by Eq. 38-3a. The particles are not relativistic.

(*a*) $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi p}{h} = \dfrac{mv}{\hbar} = \dfrac{\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.0\times10^{5}\,\text{m/s}\right)}{\left(1.055\times10^{-34}\,\text{J•s}\right)} = 2.6\times10^{9}\,\text{m}^{-1}$

$$\psi = \boxed{A\sin\left[\left(2.6\times10^{9}\,\text{m}^{-1}\right)x\right] + B\cos\left[\left(2.6\times10^{9}\,\text{m}^{-1}\right)x\right]}$$

(*b*) $k = \dfrac{2\pi}{\lambda} = \dfrac{2\pi p}{h} = \dfrac{mv}{\hbar} = \dfrac{\left(1.67\times10^{-27}\,\text{kg}\right)\left(3.0\times10^{5}\,\text{m/s}\right)}{\left(1.055\times10^{-34}\,\text{J•s}\right)} = 4.7\times10^{12}\,\text{m}^{-1}$

$$\psi = \boxed{A\sin\left[\left(4.7\times10^{12}\,\text{m}^{-1}\right)x\right] + B\cos\left[\left(4.7\times10^{12}\,\text{m}^{-1}\right)x\right]}$$

20. This is similar to the analysis done in Chapter 16 Section 6 for beats. Referring to Figure 16-17, we see the distance from one node to the next can be considered a wave packet. We add the two wave functions, employ the trigonometric identity for the sine of a sum of two angles, and then find the distance between nodes. The wave numbers are related to the wavelengths by $k = \dfrac{2\pi}{\lambda}$. Since $\lambda_1 \approx \lambda_2$, it is also true that $k_1 \approx k_2$ and so $\frac{1}{2}\left(k_1 + k_2\right) \approx k_{\text{avg}}$. We define $\Delta k = k_1 - k_2$.

$$\psi = \psi_1 + \psi_2 = A\sin k_1 x + A\sin k_2 x = A\left(\sin k_1 x + \sin k_2 x\right) = 2A\sin\left[\tfrac{1}{2}\left(k_1 + k_2\right)x\right]\cos\left[\tfrac{1}{2}\left(k_1 - k_2\right)x\right]$$
$$= 2A\sin k_{\text{avg}} x\cos\left[\tfrac{1}{2}\left(\Delta k\right)x\right]$$

The sum function will take on a value of 0 if $\frac{1}{2}\left(\Delta k\right)x = \left(n + \frac{1}{2}\right)\pi$, $n = 0,1,2\ldots$. The distance between these nodal locations is found as follows.

$$x = \frac{2\left(n+\frac{1}{2}\right)\pi}{\Delta k} = \frac{\left(2n+1\right)\pi}{\Delta k},\ n = 0,1,2\ldots. \quad\rightarrow\quad \Delta x = \frac{\left(2\left(n+1\right)+1\right)\pi}{\Delta k} - \frac{\left(2n+1\right)\pi}{\Delta k} = \frac{2\pi}{\Delta k}$$

Now use the de Broglie relationship between wavelength and momentum.

$$p = \frac{h}{\lambda} = \hbar k \quad\rightarrow\quad \Delta k = \frac{\Delta p}{\hbar} \ ;\ \Delta x = \frac{2\pi}{\Delta k} = \frac{2\pi\hbar}{\Delta p} \quad\rightarrow\quad \boxed{\Delta x \Delta p = h}$$

21. The minimum speed corresponds to the lowest energy state. The energy is given by Eq. 38-13.

$$E_{\text{min}} = \frac{h^2}{8m\ell^2} = \tfrac{1}{2}mv_{\text{min}}^2 \quad\rightarrow\quad v_{\text{min}} = \frac{h}{2m\ell} = \frac{6.63\times10^{-34}\,\text{J•s}}{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(0.20\times10^{-9}\,\text{m}\right)} = \boxed{1.8\times10^{6}\,\text{m/s}}$$

22. We assume the particle is not relativistic. The energy levels are given by Eq. 38-13, and the wave functions are given by Eq. 38-14.

$$E_n = \frac{h^2 n^2}{8m\ell^2} = \frac{p^2}{2m} \quad\rightarrow\quad p_n = \frac{hn}{2\ell} \ ;\ \psi_n = \sqrt{\frac{2}{\ell}}\sin\left(\frac{n\pi x}{\ell}\right) \quad\rightarrow\quad \frac{n\pi}{\ell} = k_n = \frac{2\pi}{\lambda_n} \quad\rightarrow$$

$\lambda_n = \dfrac{2\ell}{n} = \dfrac{h}{p_n}$, which is the de Broglie wavelength

23. (*a*) The longest wavelength photon will be the photon with the lowest frequency, and thus the lowest energy. The difference between energy levels increases with high states, so the lowest energy transition is from $n = 2$ to $n = 1$. The energy levels are given by Eq. 38-13.

$$E_n = n^2\frac{h^2}{8m\ell^2} = n^2 E_1$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\lambda = \frac{c}{\nu} = \frac{hc}{\Delta E} = \frac{hc}{E_2 - E_1} = \frac{hc}{4E_1 - E_1} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{3\left(9.0\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = \boxed{4.6\times10^{-8}\,\text{m}}$$

(*b*) We use the ground state energy and Eq. 38-13.

$$E_1 = \frac{h^2}{8m\ell^2} \quad \rightarrow$$

$$\ell = \frac{h}{\sqrt{8mE_1}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\sqrt{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(9.0\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}} = \boxed{2.0\times10^{-10}\,\text{m}}$$

24. The energy levels for a particle in a rigid box are given by Eq. 38-13. Use that equation, evaluated for $n = 4$ and $n = 1$, to calculate the width of the box. We also use Eq. 37-3.

$$\Delta E = h\nu = \frac{hc}{\lambda} = E_4 - E_1 = \frac{h^2}{8m\ell^2}\left(4^2 - 1^2\right) \quad \rightarrow$$

$$\ell = \sqrt{\frac{15h\lambda}{8mc}} = \sqrt{\frac{15\left(6.63\times10^{-34}\,\text{J•s}\right)\left(340\times10^{-9}\,\text{m}\right)}{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}} = \boxed{1.2\times10^{-9}\,\text{m}}$$

25. We assume the particle is not relativistic. The energy levels give the kinetic energy of the particles in the box.

$$E_1 = \frac{h^2}{8m\ell^2} = \frac{p_1^2}{2m} \quad \rightarrow \quad p_1^2 = \frac{h^2}{4\ell^2} \quad \rightarrow \quad \left|p_1\right| = \frac{h}{2\ell} \quad \rightarrow \quad \Delta p \approx 2\left|p_1\right| = \frac{h}{\ell}$$

$$\Delta x \Delta p \approx \ell\frac{h}{\ell} = h$$

This is consistent with the uncertainty principle.

26. The longest wavelength photon will be the photon with the lowest frequency, and thus the lowest energy. The difference between energy levels increases with high states, so the lowest energy transition is from $n = 2$ to $n = 1$. The energy levels are given by Eq. 38-13.

$$\Delta E = h\nu = \frac{hc}{\lambda} = E_2 - E_1 = \frac{h^2}{8m\ell^2}\left(2^2 - 1^2\right) \quad \rightarrow$$

$$\ell = \sqrt{\frac{3h\lambda}{8mc}} = \sqrt{\frac{3\left(6.63\times10^{-34}\,\text{J•s}\right)\left(610\times10^{-9}\,\text{m}\right)}{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}} = \boxed{7.4\times10^{-10}\,\text{m}}$$

27. The energy levels for a particle in an infinite potential well are given by Eq. 38-13. The wave functions are given by Eq. 38-14 with $A = \sqrt{\frac{2}{\ell}}$.

$$E_1 = \frac{h^2}{8m\ell^2} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)^2}{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(2.0\times10^{-9}\,\text{m}\right)^2\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 9.424\times10^{-2}\,\text{eV} \approx \boxed{0.094\,\text{eV}}$$

$$E_2 = 2^2E_1 = 4\left(9.424\times10^{-2}\,\text{eV}\right) = \boxed{0.38\,\text{eV}}$$

$$E_3 = 3^2E_1 = 9\left(9.424\times10^{-2}\,\text{eV}\right) = \boxed{0.85\,\text{eV}}$$

$$E_4 = 4^2E_1 = 16\left(9.424\times10^{-2}\,\text{eV}\right) = \boxed{1.5\,\text{eV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\psi_n = \sqrt{\frac{2}{\ell}}\sin\left(\frac{n\pi}{\ell}x\right)\ ;\ \ \psi_1 = \sqrt{\frac{2}{2.0\,\text{nm}}}\sin\left(\frac{\pi}{2.0\,\text{nm}}x\right) = \boxed{\left(1.0\,\text{nm}^{-1/2}\right)\sin\left[\left(1.6\,\text{nm}^{-1}\right)x\right]}$$

$$\psi_2 = \boxed{\left(1.0\,\text{nm}^{-1/2}\right)\sin\left[\left(3.1\,\text{nm}^{-1}\right)x\right]}\ ;\ \psi_3 = \boxed{\left(1.0\,\text{nm}^{-1/2}\right)\sin\left[\left(4.7\,\text{nm}^{-1}\right)x\right]}\ ;$$

$$\psi_4 = \boxed{\left(1.0\,\text{nm}^{-1/2}\right)\sin\left[\left(6.3\,\text{nm}^{-1}\right)x\right]}$$

28. The wave functions for an infinite square well are given by Eq. 38-14.

$$\psi_n = A\sin\left(\frac{n\pi}{\ell}x\right)\ ;\ |\psi_n|^2 = A^2\sin^2\left(\frac{n\pi}{\ell}x\right)$$

(*a*) The maxima occur at locations where $|\psi_n|^2 = A^2$.

$$\sin^2\left(\frac{n\pi}{\ell}x\right) = 1 \ \rightarrow\ \frac{n\pi}{\ell}x = \left(m+\tfrac{1}{2}\right)\pi,\ m = 0,1,2,\cdots n-1 \ \rightarrow$$

$$\boxed{x_{\text{max}} = \left(\frac{2m+1}{2n}\right)\ell,\ m = 0,1,2,\cdots n-1}$$

The values of *m* are limited because $x \le \ell$.

(*b*) The minima occur at locations where $|\psi_n|^2 = 0$.

$$\sin^2\left(\frac{n\pi}{\ell}x\right) = 0 \ \rightarrow\ \frac{n\pi}{\ell}x = m\pi,\ m = 0,1,2,\cdots n \ \rightarrow\ \boxed{x_{\text{min}} = \frac{m}{n}\ell,\ m = 0,1,2,\cdots n}$$

29. The energy levels for a particle in a rigid box are given by Eq. 38-13. We substitute the appropriate mass in for each part of the problem.

(*a*) For an electron we have the following:

$$E = \frac{h^2n^2}{8m\ell^2} = \frac{\left(6.63\times10^{-34}\,\text{J}\bullet\text{s}\right)^2}{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(2.0\times10^{-14}\,\text{m}\right)^2\left(1.60\times10^{-13}\,\text{J/MeV}\right)} = \boxed{940\,\text{MeV}}$$

(*b*) For a neutron we have the following:

$$E = \frac{h^2n^2}{8m\ell^2} = \frac{\left(6.63\times10^{-34}\,\text{J}\bullet\text{s}\right)^2}{8\left(1.675\times10^{-27}\,\text{kg}\right)\left(2.0\times10^{-14}\,\text{m}\right)^2\left(1.60\times10^{-13}\,\text{J/MeV}\right)} = \boxed{0.51\,\text{MeV}}$$

(*c*) For a proton we have the following:

$$E = \frac{h^2n^2}{8m\ell^2} = \frac{\left(6.63\times10^{-34}\,\text{J}\bullet\text{s}\right)^2}{8\left(1.673\times10^{-27}\,\text{kg}\right)\left(2.0\times10^{-14}\,\text{m}\right)^2\left(1.60\times10^{-13}\,\text{J/MeV}\right)} = \boxed{0.51\,\text{MeV}}$$

30. The energy released is calculated by Eq. 38-13, with $n = 2$ for the initial state and $n = 1$ for the final state.

$$\Delta E = E_2 = E_1 = \left(2^2 - 1^1\right)\frac{h^2}{8m\ell^2} = \frac{3\left(6.63\times10^{-34}\,\text{J}\bullet\text{s}\right)^2}{8\left(1.67\times10^{-27}\,\text{kg}\right)\left(1.0\times10^{-14}\,\text{m}\right)^2\left(1.60\times10^{-13}\,\text{J/MeV}\right)}$$

$$= \boxed{6.17\,\text{MeV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

31. (*a*) The ground state energy is given by Eq. 38-13 with $n = 1$.

$$E_1 = \left.\frac{h^2 n^2}{8m\ell^2}\right|_{n=1} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)^2(1)}{8(32\,\text{u})\left(1.66\times10^{-27}\,\text{kg/u}\right)\left(4.0\times10^{-3}\,\text{m}\right)^2\left(1.60\times10^{-19}\,\text{J/eV}\right)}$$

$$= 4.041\times10^{-19}\,\text{eV} \approx \boxed{4.0\times10^{-19}\,\text{eV}}$$

(*b*) We equate the thermal energy expression to Eq. 38-13 in order to find the quantum number.

$$\tfrac{1}{2}kT = \frac{h^2 n^2}{8m\ell^2} \quad \rightarrow$$

$$n = 2\sqrt{kTm}\,\frac{\ell}{h} = 2\sqrt{\left(1.38\times10^{-23}\,\text{J/K}\right)(300\,\text{K})(32\,\text{u})\left(1.66\times10^{-27}\,\text{kg/u}\right)}\,\frac{\left(4.0\times10^{-3}\,\text{m}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)}$$

$$= 1.789\times10^{8} \approx \boxed{2\times10^{8}}$$

(*c*) Use Eq. 38-13 with a large-*n* approximation.

$$\Delta E = E_{n+1} - E_n = \frac{h^2}{8m\ell^2}\left[(n+1)^2 - n^2\right] = \frac{h^2}{8m\ell^2}(2n+1) \approx 2n\frac{h^2}{8m\ell^2} = 2nE_1$$

$$= 2\left(1.789\times10^{8}\right)\left(4.041\times10^{-19}\,\text{eV}\right) = \boxed{1.4\times10^{-10}\,\text{eV}}$$

32. Because the wave function is normalized, the probability is found as in Example 38-8. Change the variable to $\theta = \dfrac{n\pi x}{\ell}$, and then $d\theta = \dfrac{n\pi}{\ell}dx$.

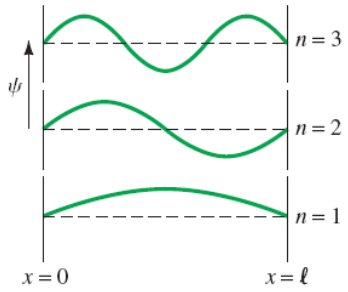
$$P = \int_{x_1}^{x_2}|\psi_n|^2\,dx = \frac{2}{\ell}\int_{x_1}^{x_2}\sin^2\frac{n\pi x}{\ell}\,dx = \frac{2}{\ell}\frac{\ell}{n\pi}\int_{n\pi x_1/\ell}^{n\pi x_2/\ell}\sin^2\theta\,d\theta = \frac{2}{n\pi}\int_{0.35n\pi}^{0.65n\pi}\sin^2\theta\,d\theta$$

$$= \frac{2}{n\pi}\left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_{0.35n\pi}^{0.65n\pi}$$

(*a*) For the $n = 1$ state we have the following:

$$P = \frac{2}{\pi}\left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_{0.35\pi}^{0.65\pi} = \frac{2}{\pi}\left[\tfrac{1}{2}(0.30\pi) - \tfrac{1}{4}(\sin 1.3\pi - \sin 0.70\pi)\right] = 0.5575 \approx 0.56$$

(*b*) For the $n = 5$ state we have the following:



$$P = \frac{2}{5\pi}\left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_{1.75n\pi}^{3.25n\pi} = \frac{2}{5\pi}\left[\tfrac{1}{2}(1.5\pi) - \tfrac{1}{4}(\sin 6.5\pi - \sin 3.5\pi)\right] = 0.2363 \approx 0.24$$

(*c*) For the $n = 20$ state we have the following:

$$P = \frac{2}{20\pi}\left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_{7\pi}^{13\pi} = \frac{1}{10\pi}\left[\tfrac{1}{2}6\pi - \tfrac{1}{4}(\sin 26\pi - \sin 14\pi)\right] = 0.30$$

(*d*) The classical prediction would be that the particle has an equal probability of being at any location, so the probability of being in the given range is $P = \dfrac{0.65\,\text{nm} - 0.35\,\text{nm}}{1.00\,\text{nm}} = 0.30$. We see that the probabilities approach the classical value for large *n*.

33. Consider Figure 38-9, copied here. To consider the problem with the boundaries shifted, we would not expect any kind of physics to change. So we expect the same wave functions in terms of their actual shape, and we expect the same energies if all that is done is to change the labeling of the walls to $x = -\tfrac{1}{2}\ell$ and $x = \tfrac{1}{2}\ell$. The mathematical descriptions of the wave functions would change because of the change of coordinates. All we should have to do is

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

shift the origin of coordinates to the right by $\frac{1}{2}\ell$. Thus we might expect the following wave functions and energies.

$$\psi_n = \sqrt{\frac{2}{\ell}}\sin\left(\frac{n\pi}{\ell}x\right) \quad \rightarrow$$

$$\psi_n = \sqrt{\frac{2}{\ell}}\sin\left[\frac{n\pi}{\ell}\left(x+\tfrac{1}{2}\ell\right)\right] = \sqrt{\frac{2}{\ell}}\sin\left(\frac{n\pi}{\ell}x+\tfrac{1}{2}n\pi\right)$$

$$n=1:\ \psi_1 = \sqrt{\frac{2}{\ell}}\sin\left(\frac{\pi}{\ell}x+\tfrac{1}{2}\pi\right) = \boxed{\sqrt{\frac{2}{\ell}}\cos\left(\frac{\pi}{\ell}x\right)};\ E_1 = \boxed{\frac{h^2}{8m\ell^2}}$$

$$n=2:\ \psi_2 = \sqrt{\frac{2}{\ell}}\sin\left(\frac{2\pi}{\ell}x+\pi\right) = \boxed{-\sqrt{\frac{2}{\ell}}\sin\left(\frac{2\pi}{\ell}x\right)};\ E_2 = \boxed{\frac{4h^2}{8m\ell^2}}$$

$$n=3:\ \psi_3 = \sqrt{\frac{2}{\ell}}\sin\left(\frac{3\pi}{\ell}x+\tfrac{3}{2}\pi\right) = \sqrt{\frac{2}{\ell}}\sin\left(\frac{3\pi}{\ell}x+\tfrac{1}{2}\pi+\pi\right) = -\sqrt{\frac{2}{\ell}}\sin\left(\frac{3\pi}{\ell}x+\tfrac{1}{2}\pi\right)$$

$$= \boxed{-\sqrt{\frac{2}{\ell}}\cos\left(\frac{3\pi}{\ell}x\right)};\ E_3 = \boxed{\frac{9h^2}{8m\ell^2}}$$

$$n=4:\ \psi_4 = \sqrt{\frac{2}{\ell}}\sin\left(\frac{4\pi}{\ell}x+2\pi\right) = \boxed{\sqrt{\frac{2}{\ell}}\sin\left(\frac{4\pi}{\ell}\right)};\ E_4 = \boxed{\frac{16h^2}{8m\ell^2}}$$

For any higher orders, we simply add another 2π of phase to the arguments of the above functions. They can be summarized as follows.

$$n \text{ odd: } \psi = \left[(-1)^{(n-1)/2}\right]\sqrt{\frac{2}{\ell}}\cos\left(\frac{n\pi x}{\ell}\right),\ E_n = \frac{n^2h^2}{8m\ell^2}$$

$$n \text{ even: } \psi = \left[(-1)^{n/2}\right]\sqrt{\frac{2}{\ell}}\sin\left(\frac{n\pi x}{\ell}\right),\ E_n = \frac{n^2h^2}{8m\ell^2}$$

Of course, this is not a "solution" in the sense that we have not derived these solutions from the Schrödinger equation. We now show a solution that arises from solving the Schrödinger equation. We follow the development as given in Section 38-8.

As suggested, let $\psi(x) = A\sin(kx+\phi)$. For a region where $U(x)=0,\ k = \sqrt{\frac{2mE}{\hbar^2}}$ (Eq. 38-11a).

The boundary conditions are $\psi\left(-\frac{1}{2}\ell\right) = A\sin\left(-\frac{1}{2}k\ell+\phi\right) = 0$ and $\psi\left(\frac{1}{2}\ell\right) = A\sin\left(\frac{1}{2}k\ell+\phi\right) = 0$. To guarantee the boundary conditions, we must have the following:

$$A\sin\left(-\tfrac{1}{2}k\ell+\phi\right)=0 \ \rightarrow\ -\tfrac{1}{2}k\ell+\phi = m\pi\ ;\ A\sin\left(\tfrac{1}{2}k\ell+\phi\right)=0 \ \rightarrow\ \tfrac{1}{2}k\ell+\phi = n\pi$$

Both *n* and *m* are integers. Add these two results, and subtract the two results, to get two new expressions.

$$\begin{matrix}\frac{1}{2}k\ell+\phi = n\pi \\ -\frac{1}{2}k\ell+\phi = m\pi\end{matrix} \ \rightarrow\ \phi = \tfrac{1}{2}(n+m)\pi\ ;\ k = \frac{1}{\ell}(n-m)\pi$$

So again we have an energy quantization, with $E = \frac{\hbar^2k^2}{2m} = \frac{\hbar^2\pi^2(n-m)^2}{2m\ell^2} = \frac{h^2(n-m)^2}{8m\ell^2}$. Note that $m=n$ is not allowed, because this leads to $k=0,\ \phi=n\pi,$ and $\psi(x)\equiv 0$.

Next we normalize the wave functions. We use an indefinite integral from Appendix B-4.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\psi(x) = A\sin(kx+\phi) = A\sin\left[\frac{1}{\ell}(n-m)\pi x + \tfrac{1}{2}(n+m)\pi\right]$$

$$\int_{-\infty}^{\infty} |\psi|^2\,dx = \int_{-\frac{1}{2}\ell}^{\frac{1}{2}\ell} A^2\sin^2\left[\frac{1}{\ell}(n-m)\pi x + \tfrac{1}{2}(n+m)\pi\right]dx = 1$$

$$\text{let } \theta = \frac{1}{\ell}(n-m)\pi x + \tfrac{1}{2}(n+m)\pi \;\rightarrow\; dx = \frac{\ell}{(n-m)\pi}d\theta$$

$$x = \tfrac{1}{2}\ell \;\rightarrow\; \theta = n\pi \;;\; x = -\tfrac{1}{2}\ell \;\rightarrow\; \theta = m\pi$$

$$1 = \int_{-\infty}^{\infty} |\psi|^2\,dx = \frac{A^2\ell}{(n-m)\pi}\int_{m\pi}^{n\pi}\sin^2\theta\,d\theta = \frac{A^2\ell}{(n-m)\pi}\left(\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right)_{m\pi}^{n\pi}\frac{A^2\ell}{(n-m)\pi}\frac{(n-m)\pi}{2} = \frac{A^2\ell}{2}$$

$$A^2 = \frac{2}{\ell} \;\rightarrow\; A = \sqrt{\frac{2}{\ell}}$$

This is the same as in Section 38-8. Finally, let us examine a few allowed cases.

$$n=1,\ m=0:\ k=\frac{\pi}{\ell},\ \phi=\tfrac{1}{2}\pi \;\rightarrow\; \psi_{1,0} = \sqrt{\frac{2}{\ell}}\sin\left(\frac{\pi}{\ell}x + \tfrac{1}{2}\pi\right) = \boxed{\sqrt{\frac{2}{\ell}}\cos\left(\frac{\pi}{\ell}x\right)};\ E_{1,0} = \boxed{\frac{h^2}{8m\ell^2}}$$

$$n=2,\ m=0:\ k=\frac{2\pi}{\ell},\ \phi=\pi \;\rightarrow\; \psi_{2,0} = \sqrt{\frac{2}{\ell}}\sin\left(\frac{2\pi}{\ell}x + \pi\right) = \boxed{-\sqrt{\frac{2}{\ell}}\sin\left(\frac{2\pi}{\ell}x\right)};\ E_{2,0} = \boxed{\frac{4h^2}{8m\ell^2}}$$

$$n=3,\ m=0:\ k=\frac{3\pi}{\ell},\ \phi=\tfrac{3}{2}\pi \;\rightarrow\; \psi_{3,0} = \sqrt{\frac{2}{\ell}}\sin\left(\frac{3\pi}{\ell}x + \tfrac{3}{2}\pi\right) = \sqrt{\frac{2}{\ell}}\sin\left(\frac{3\pi}{\ell}x + \tfrac{1}{2}\pi + \pi\right)$$

$$= -\sqrt{\frac{2}{\ell}}\sin\left(\frac{3\pi}{\ell}x + \tfrac{1}{2}\pi\right) = \boxed{-\sqrt{\frac{2}{\ell}}\cos\left(\frac{3\pi}{\ell}x\right)};\ E_{3,0} = \boxed{\frac{9h^2}{8m\ell^2}}$$

$$n=4,\ m=0:\ k=\frac{4\pi}{\ell},\ \phi=2\pi \;\rightarrow\; \psi_{4,0} = \sqrt{\frac{2}{\ell}}\sin\left(\frac{4\pi}{\ell}x + 2\pi\right) = \boxed{\sqrt{\frac{2}{\ell}}\sin\left(\frac{4\pi}{\ell}\right)};\ E_{4,0} = \boxed{\frac{16h^2}{8m\ell^2}}$$

These are the same results as those obtained in the less formal method. Other combinations of *m* and *n* would give essentially these same results for the lowest four energies and the associated wave functions. For example, consider $n=4,\ m=1$.

$$n=4,\ m=1:\ k=\frac{3\pi}{\ell},\ \phi=\tfrac{5}{2}\pi \;\rightarrow\; \psi_{4,1} = \sqrt{\frac{2}{\ell}}\sin\left(\frac{3\pi}{\ell}x + \tfrac{5}{2}\pi\right) = \sqrt{\frac{2}{\ell}}\sin\left(\frac{3\pi}{\ell}x + \tfrac{1}{2}\pi\right)$$

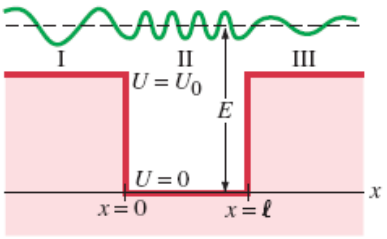
$$= \boxed{\sqrt{\frac{2}{\ell}}\cos\left(\frac{4\pi}{\ell}\right)};\ E_{4,1} = \boxed{\frac{9h^2}{8m\ell^2}}$$

We see that $\psi_{4,1} = -\psi_{3,0}$ and that both states have the same energy. Since the only difference in the wave functions is the algebraic sign, any physical measurement predictions, which depend on the absolute square of the wave function, would be the same.

34. We choose the zero of potential energy to be at the bottom of the well. Thus in free space, outside the well, the potential is $U_0 = 56\,\text{eV}$. Thus the total energy of the electron is $E = K + U_0 = 236$ eV.

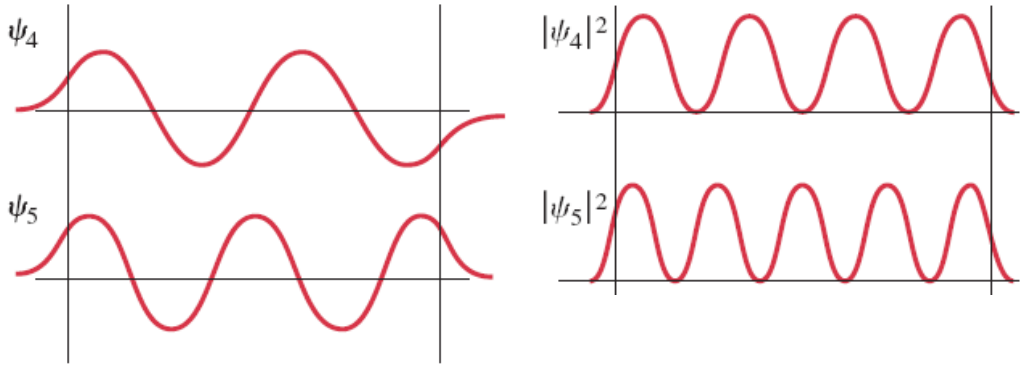
(*a*) In free space, the kinetic energy of the particle is 180 eV. Use that to find the momentum and then the wavelength.

$$K = \frac{p^2}{2m} \;\rightarrow\; p = \sqrt{2mK} = \frac{h}{\lambda} \;\rightarrow$$



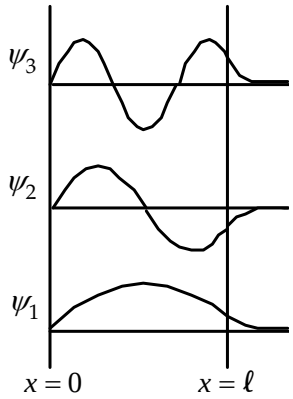
© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\lambda = \frac{h}{\sqrt{2mK}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left[2\left(9.11\times10^{-31}\,\text{kg}\right)\left(180\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)\right]^{1/2}} = \boxed{9.15\times10^{-11}\,\text{m}}$$



(*b*) Over the well, the kinetic energy is 236 eV.

$$\lambda = \frac{h}{\sqrt{2mK}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left[2\left(9.11\times10^{-31}\,\text{kg}\right)\left(236\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)\right]^{1/2}} = \boxed{7.99\times10^{-11}\,\text{m}}$$



(*c*) The diagram is qualitatively the same as Figure 38-14, reproduced here. Notice that the wavelength is longer when the particle is not over the well, and shorter when the particle is over the well.

35. We pattern our answer after Figure 38-13.

36. (*a*) We assume that the lowest three states are bound in the well, so that $E < U_0$. See the diagrams for the proposed wave functions. Note that, in the well, the wave functions are similar to those for the infinite well. Outside the well, for $x > \ell$, the wave functions are drawn with an exponential decay, similar to the right side of Figure 38-13.

(*b*) In the region $x < 0$, $\boxed{\psi = 0}$.

In the well, with $0 < x < \ell$, the wave function is similar to that of a free particle or a particle in an infinite potential well, since $U = 0$.

Thus $\boxed{\psi = A\sin kx + B\sin kx}$, where $k = \dfrac{\sqrt{2mE}}{\hbar}$.

In the region $x > \ell$, $\boxed{\psi = De^{-Gx}}$, where $G = \dfrac{\sqrt{2m\left(U_0 - E\right)}}{\hbar}$.

37. We will consider the "left" wall of the square well, using Figure 38-12,l and assume that our answer is applicable at either wall due to the symmetry of the potential well. As in Section 38-9, let $\psi = Ce^{Gx}$ for $x < 0$, with G given in Eq. 38-16. Since the wave function must be continuous, $\psi\left(x = 0\right) = C$. The energy of the electron is to be its ground state energy, approximated by Eq. 38-

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

13 for the infinite well. If that energy is much less than the depth of the well, our approximation will be reasonable. We want to find the distance x for which $\psi(x) = 0.010\psi(0)$.

$$E = \frac{h^2}{8m\ell^2} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)^2}{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(0.16\times10^{-9}\,\text{m}\right)^2\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 14.73\,\text{eV} \ll U_0$$

$$\frac{\psi(x)}{\psi(0)} = \frac{Ce^{Gx}}{C} = e^{Gx} = 0.010 \;\rightarrow\; x = \frac{\ln(0.010)}{G} = \frac{\hbar\ln(0.010)}{\sqrt{2m(U_0 - E)}}$$

$$x = \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)\ln(0.010)}{\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)(2000\,\text{eV} - 14.73\,\text{eV})\left(1.60\times10^{-19}\,\text{J/eV}\right)}} = -2.0\times10^{-11}\,\text{m}$$

The wave function will be 1.0% of its value at the walls at a distance of $\boxed{2.0\times10^{-11}\,\text{m} = 0.020\,\text{nm}}$ from the walls.

38. We use Eqs. 38-17a and 38-17b.

$$T = e^{-2G\ell} \;\rightarrow\; G = -\frac{\ln T}{2\ell} \;;\; G = \sqrt{\frac{2m(U_0 - E)}{\hbar^2}} = -\frac{\ln T}{2\ell} \;\rightarrow$$

$$E = U_0 - \frac{\hbar^2}{2m}\left(-\frac{\ln T}{2\ell}\right)^2 = 14\,\text{eV} - \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)^2}{2\left(9.11\times10^{-31}\,\text{kg}\right)}\left(-\frac{\ln(0.00050)}{2\left(0.85\times10^{-9}\,\text{m}\right)}\right)^2\left(\frac{1}{1.60\times10^{-19}\,\text{J/eV}}\right)$$

$$= 14\,\text{eV} - 0.76\,\text{eV} = 13.24\,\text{eV} \approx \boxed{13\,\text{eV}}$$

39. We use Eqs. 38-17a and 38-17b to solve for the particle's energy.

$$T = e^{-2G\ell} \;\rightarrow\; G = -\frac{\ln T}{2\ell} \;;\; G = \sqrt{\frac{2m(U_0 - E)}{\hbar^2}} = -\frac{\ln T}{2\ell} \;\rightarrow$$

$$E = U_0 - \frac{\hbar^2}{2m}\left(-\frac{\ln T}{2\ell}\right)^2 = 18\,\text{eV} - \frac{\left(1.055\times10^{-34}\,\text{J•s}\right)^2}{2\left(9.11\times10^{-31}\,\text{kg}\right)}\left(-\frac{\ln(0.010)}{2\left(0.55\times10^{-9}\,\text{m}\right)}\right)^2\left(\frac{1}{1.60\times10^{-19}\,\text{J/eV}}\right)$$

$$= 17.33\,\text{eV} \approx \boxed{17\,\text{eV}}$$

40. We use Eqs. 38-17a and 38-17b to solve for the transmission coefficient, which can be interpreted in terms of probability. For the mass of the helium nucleus, we take the mass of 2 protons and 2 neutrons, ignoring the (small) binding energy.
Proton:

$$G = \frac{\sqrt{2m(U_0 - E)}}{\hbar} = \frac{\sqrt{2\left(1.67\times10^{-27}\,\text{kg}\right)(20.0\,\text{MeV})\left(1.60\times10^{-13}\,\text{J/MeV}\right)}}{\left(1.055\times10^{-34}\,\text{J•s}\right)} = 9.799\times10^{14}\,\text{m}^{-1}$$

$$2G\ell = 2\left(9.799\times10^{14}\,\text{m}^{-1}\right)\left(3.6\times10^{-15}\,\text{m}\right) = 7.056 \;;\; T_{\text{proton}} = e^{-2G\ell} = e^{-7.056} = \boxed{8.6\times10^{-4}}$$

Helium: Mass = $2m_{\text{proton}} + 2m_{\text{neutron}} = 2\left(1.673\times10^{-27}\,\text{kg}\right) + 2\left(1.675\times10^{-27}\,\text{kg}\right) = 6.70\times10^{-27}\,\text{kg}$.

$$G = \frac{\sqrt{2m(U_0 - E)}}{\hbar} = \frac{\sqrt{2\left(6.70\times10^{-27}\,\text{kg}\right)(20.0\,\text{MeV})\left(1.60\times10^{-13}\,\text{J/MeV}\right)}}{\left(1.055\times10^{-34}\,\text{J•s}\right)} = 1.963\times10^{15}\,\text{m}^{-1}$$

$$2G\ell = 2\left(1.963\times10^{15}\,\text{m}^{-1}\right)\left(3.6\times10^{-15}\,\text{m}\right) = 14.112 \;;\; T_{\text{He}} = e^{-2G\ell} = e^{-14.112} = \boxed{7.4\times10^{-7}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

41. (*a*) The probability of the electron passing through the barrier is given by Eqs. 38-17a and 38-17b.

$$T = e^{-2\ell\frac{\sqrt{2m(U_0-E)}}{\hbar}}$$

$$2\ell\frac{\sqrt{2m(U_0-E)}}{\hbar} = 2\left(0.25\times10^{-9}\,\text{m}\right)\frac{\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(1.2\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}}{\left(1.055\times10^{-34}\,\text{J•s}\right)} = 2.803$$

$$T = e^{-2.803} = 6.063\times10^{-2} \approx \boxed{6.1\%}$$

(*b*) The probability of reflecting is the probability of NOT tunneling, and so is $\boxed{93.9\%}$.

42. The transmitted current is caused by protons that tunnel through the barrier. Since current is directly proportional to the number of charges moving, the transmitted current is the incident current times the transmission coefficient. We use Eqs. 38-17a and 38-17b.

$$T = e^{-2\ell\frac{\sqrt{2m(U_0-E)}}{\hbar}}$$

$$2\ell\frac{\sqrt{2m(U_0-E)}}{\hbar} = 2\left(2.8\times10^{-13}\,\text{m}\right)\frac{\sqrt{2\left(1.67\times10^{-27}\,\text{kg}\right)\left(1.0\,\text{MeV}\right)\left(1.60\times10^{-13}\,\text{J/eV}\right)}}{\left(1.055\times10^{-34}\,\text{J•s}\right)} = 122.86$$

$$T = e^{-122.86} \;\rightarrow\; \log T = (-122.86)\log e = -53.357 \;\rightarrow\; T = 10^{-53.357} = 4.4\times10^{-54}$$

$$I = I_0T = \left(1.0\,\text{mA}\right)\left(4.4\times10^{-54}\right) = \boxed{4.4\times10^{-54}\,\text{mA}}$$

43. The transmission coefficient is given by Eqs. 38-17a and 38-17b.

(*a*) The barrier height is now $1.02\left(70\,\text{eV}\right) = 71.4\,\text{eV}$.

$$2\ell\frac{\sqrt{2m(U_0-E)}}{\hbar} = 2\left(0.10\times10^{-9}\,\text{m}\right)\frac{\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(21.4\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}}{\left(1.055\times10^{-34}\,\text{J•s}\right)}$$

$$= 4.735$$

$$T = e^{-2\ell\frac{\sqrt{2m(U-E)}}{\hbar}} = e^{-4.735} = 8.782\times10^{-3} \;;\; \frac{T}{T_0} = \frac{8.782\times10^{-3}}{0.010} = 88 \;\rightarrow\; \boxed{12\%\text{ decrease}}$$

(*b*) The barrier width is now $1.02\left(0.10\,\text{nm}\right) = 0.102\,\text{nm}$.

$$2\ell\frac{\sqrt{2m(U_0-E)}}{\hbar} = 2\left(0.102\times10^{-9}\,\text{m}\right)\frac{\sqrt{2\left(9.11\times10^{-31}\,\text{kg}\right)\left(20\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}}{\left(1.055\times10^{-34}\,\text{J•s}\right)}$$

$$= 4.669$$

$$T = e^{-2\ell\frac{\sqrt{2m(U_0-E)}}{\hbar}} = e^{-4.669} = 9.382\times10^{-3} \;;\; \frac{T}{T_0} = \frac{9.382\times10^{-3}}{0.010} = 93.8 \;\rightarrow\; \boxed{6.2\%\text{ decrease}}$$

44. We assume that the wave function inside the barrier is given by a decaying exponential, so $\psi(x) = Ae^{-Gx}$.

$$T = \frac{\left|\psi(x=\ell)\right|^2}{\left|\psi(x=0)\right|^2} = \frac{\left(Ae^{-G\ell}\right)^2}{A^2} = \boxed{e^{-2G\ell}}$$

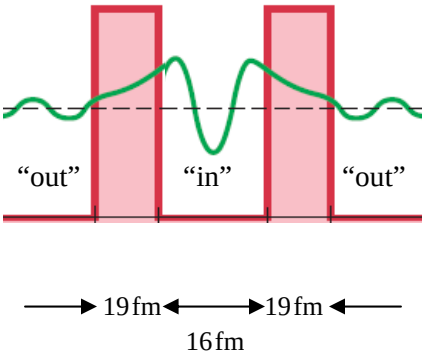
45. (*a*) We assume that the alpha particle is at the outer edge of the nucleus. The potential energy is electrostatic potential energy, and is found from Eq. 23-10.

$$U_{\text{surface}} = \frac{1}{4\pi\varepsilon_0}\frac{Q_1Q_2}{r_{\substack{\text{surface of}\\\text{nucleus}}}} = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(2)(90)\left(1.60\times10^{-19}\,\text{C}\right)^2}{8\times10^{-15}\,\text{m}}\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right)$$

$$= 32.36\,\text{MeV} \approx \boxed{32\,\text{MeV}}$$

(*b*) The kinetic energy of the free alpha particle is also its total energy. Since the free alpha has 4 MeV, by conservation of energy the alpha particle had 4 MeV of potential energy at the exit from the barrier. See the diagram, a copy of Figure 38-17, modified to show U = 0 inside the barrier, and stated in part (*c*).



$$U_{\text{exit}} = \frac{1}{4\pi\varepsilon_0}\frac{Q_1Q_2}{r_{\substack{\text{exit from}\\\text{barrier}}}} = \frac{1}{4\pi\varepsilon_0}\frac{Q_1Q_2}{r_{\substack{\text{surface of}\\\text{nucleus}}}}\frac{r_{\substack{\text{surface of}\\\text{nucleus}}}}{r_{\substack{\text{exit from}\\\text{barrier}}}}$$

$$= U_{\text{surface}}\frac{r_{\substack{\text{surface of}\\\text{nucleus}}}}{r_{\substack{\text{exit from}\\\text{barrier}}}} \quad \rightarrow$$

$$r_{\substack{\text{exit from}\\\text{barrier}}} = \frac{U_{\text{surface}}}{U_{\text{exit}}}r_{\substack{\text{surface of}\\\text{nucleus}}} = \frac{32.36\,\text{MeV}}{4\,\text{MeV}}(8\,\text{fm}) = 64.72\,\text{fm}$$

$$\Delta r = r_{\substack{\text{exit from}\\\text{barrier}}} - r_{\substack{\text{surface of}\\\text{nucleus}}} = 64.72\,\text{fm} - 8\,\text{fm} = 56.72\,\text{fm} \approx \boxed{57\,\text{fm}}$$

(*c*) We now model the barrier as being rectangular, with a width of $r_{\text{barrier}} = \frac{1}{3}(56.72\,\text{fm}) = 18.9\,\text{fm}$. The barrier exists at both boundaries of the nucleus, if we imagine the nucleus as 1-dimensional. See the diagram (not to scale). We calculate the speed of the alpha particle and use that to find the frequency of collision with the barrier.

$$E = K = \tfrac{1}{2}mv^2 \quad \rightarrow$$

$$v = \sqrt{\frac{2E}{m}} = \sqrt{\frac{2\left(4\,\text{MeV}\right)\left(1.60\times10^{-13}\,\text{J/MeV}\right)}{4\left(1.67\times10^{-27}\,\text{kg}\right)}}$$

$$= 1.38\times10^7\,\text{m/s} \approx \boxed{1.4\times10^7\,\text{m/s}}$$

Note that the speed of the alpha is less than 5% of the speed of light, so we can treat the alpha without using relativistic concepts. The time between collisions is the diameter of the nucleus (16 fm) divided by the speed of the alpha particles. The frequency of collision is the reciprocal of the time between collisions.

$$f = \frac{v}{d} = \frac{1.38\times10^7\,\text{m/s}}{16\times10^{-15}\,\text{m}} = 8.625\times10^{20}\,\text{collisions/s} \approx \boxed{8.6\times10^{20}\,\text{collisions/s}}$$

If we multiply this collision frequency times the probability of tunneling, T, then we will have an estimate of "effective" collisions/s, or in other words, the decays/s. The reciprocal of this effective frequency is an estimate of the time the alpha spends inside the nucleus – the life of the uranium nucleus.

$$G = \frac{\sqrt{2m(U_0 - E)}}{\hbar} = \frac{\sqrt{2(4)(1.67\times10^{-27}\,\text{kg})(32.36\,\text{MeV} - 4\,\text{MeV})(1.60\times10^{-13}\,\text{J/MeV})}}{(1.055\times10^{-34}\,\text{J•s})}$$

$$= 2.33\times10^{15}\,\text{m}^{-1}$$

$$T = e^{-2G\ell} \;;\; \text{Lifetime} = \frac{1}{fT} = \frac{1}{fe^{-2G\ell}} = \frac{1}{(8.625\times10^{20}\,\text{collisions/s})e^{-2(2.33\times10^{15}\,\text{m}^{-1})(18.9\times10^{-15}\,\text{m})}}$$

$$= 2.06\times10^{17}\,\text{s}\left(\frac{1\,\text{yr}}{3.156\times10^{7}\,\text{s}}\right) \approx \boxed{7\times10^{9}\,\text{yr}}$$

46. We find the lifetime of the particle from Eq. 38-2.

$$\Delta t \geq \frac{\hbar}{\Delta E} = \frac{(1.055\times10^{-34}\,\text{J•s})}{(2.5\,\text{GeV})(1.60\times10^{-10}\,\text{J/GeV})} = \boxed{2.6\times10^{-25}\,\text{s.}}$$

47. We use the radius as the uncertainty in position for the neutron. We find the uncertainty in the momentum from Eq. 38-1. If we assume that the lowest value for the momentum is the least uncertainty, we estimate the lowest possible kinetic energy (non-relativistic) as

$$E = \frac{(\Delta p)^2}{2m} = \frac{\left(\frac{\hbar}{\Delta x}\right)^2}{2m} = \frac{(1.055\times10^{-34}\,\text{kg•m/s})^2}{2(1.67\times10^{-27}\,\text{kg})(1.2\times10^{-15}\,\text{m})^2} = 2.314\times10^{-12}\,\text{J}\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right)$$

$$= 14.46\,\text{MeV} \approx \boxed{14\ \text{MeV}}$$

48. The energy levels for a particle in an infinite potential well are given by Eq. 38-13. The wave functions are given by Eq. 38-14. with $A = \sqrt{\frac{2}{\ell}}$.

(*a*) $E_1 = \frac{h^2}{8m\ell^2} = \frac{(6.63\times10^{-34}\,\text{J•s})^2}{8(1.67\times10^{-27}\,\text{kg})(2.5\times10^{-15}\,\text{m})^2(1.60\times10^{-13}\,\text{J/MeV})} = 32.90\,\text{MeV} \approx \boxed{33\,\text{MeV}}$

$E_2 = 2^2E_1 = 4(32.90\,\text{MeV}) = \boxed{130\,\text{MeV}}$; $E_3 = 3^2E_1 = 9(32.90\,\text{MeV}) = \boxed{300\,\text{MeV}}$ (2 sig. fig.)

$E_4 = 4^2E_1 = 16(32.90\,\text{MeV}) = \boxed{530\,\text{MeV}}$

(*b*) $\psi_n = \sqrt{\frac{2}{\ell}}\sin\left(\frac{n\pi}{\ell}x\right)$

$$\psi_1 = \sqrt{\frac{2}{2.5\times10^{-15}\,\text{m}}}\sin\left(\frac{\pi}{2.5\times10^{-15}\,\text{m}}x\right) = \boxed{(2.8\times10^{7}\,\text{m}^{-1/2})\sin\left[(1.3\times10^{15}\,\text{m}^{-1})x\right]}$$

$$\psi_2 = \sqrt{\frac{2}{2.5\times10^{-15}\,\text{m}}}\sin\left(\frac{2\pi}{2.5\times10^{-15}\,\text{m}}x\right) = \boxed{(2.8\times10^{7}\,\text{m}^{-1/2})\sin\left[(2.5\times10^{15}\,\text{m}^{-1})x\right]}$$

$$\psi_3 = \sqrt{\frac{2}{2.5\times10^{-15}\,\text{m}}}\sin\left(\frac{3\pi}{2.5\times10^{-15}\,\text{m}}x\right) = \boxed{(2.8\times10^{7}\,\text{m}^{-1/2})\sin\left[(3.8\times10^{15}\,\text{m}^{-1})x\right]}$$

$$\psi_4 = \sqrt{\frac{2}{2.5\times10^{-15}\,\text{m}}}\sin\left(\frac{4\pi}{2.5\times10^{-15}\,\text{m}}x\right) = \boxed{(2.8\times10^{7}\,\text{m}^{-1/2})\sin\left[(5.0\times10^{15}\,\text{m}^{-1})x\right]}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) $\Delta E = E_2 - E_1 = 4E_1 - E_1 = 3E_1 = 3(32.90\,\text{MeV}) = 98.7\,\text{MeV} \approx \boxed{99\,\text{MeV}}$

$$\Delta E = \frac{hc}{\lambda} \quad \rightarrow \quad \lambda = \frac{hc}{\Delta E} = \frac{(6.63\times10^{-34}\,\text{J•s})(3.00\times10^{8}\,\text{m/s})}{(98.7\,\text{MeV})(1.60\times10^{-13}\,\text{J/MeV})} = \boxed{1.3\times10^{-14}\,\text{m}} = 13\,\text{fm}$$

This is in the gamma-ray region of the EM spectrum, as seen in Fig. 31-12.

49. We find the wavelength of the protons from their kinetic energy, and then use the two-slit interference formulas from Chapter 34, with a small angle approximation. If the protons were accelerated by a 650-volt potential difference, then they will have 650 eV of kinetic energy.

$$\lambda = \frac{h}{p} = \frac{h}{\sqrt{2m_0K}} \;\; ; \;\; d\sin\theta = m\lambda,\; m = 1, 2, \ldots \;\; ; \;\; y = \ell\tan\theta$$

$$\sin\theta = \tan\theta \quad \rightarrow \quad \frac{m\lambda}{d} = \frac{y}{\ell} \quad \rightarrow \quad y = \frac{m\lambda\ell}{d},\; m = 1, 2, \ldots \quad \rightarrow$$

$$\Delta y = \frac{\lambda\ell}{d} = \frac{h\ell}{d\sqrt{2m_0K}} = \frac{(6.63\times10^{-34}\,\text{J•s})(18\,\text{m})}{(8.0\times10^{-4}\,\text{m})\sqrt{2(1.67\times10^{-27}\,\text{kg})(650\,\text{eV})(1.60\times10^{-19}\,\text{J/eV})}}$$

$$= \boxed{2.5\times10^{-8}\,\text{m}}$$

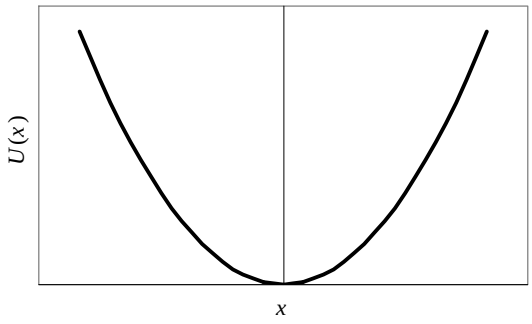
50. We assume that the particles are not relativistic. Conservation of energy is used to find the speed of each particle. That speed then can be used to find the momentum and finally the de Broglie wavelength. We let the magnitude of the accelerating potential difference be *V*.

$$U_{\text{initial}} = K_{\text{final}} \quad \rightarrow \quad eV = \tfrac{1}{2}mv^2 \quad \rightarrow \quad v = \sqrt{\frac{2eV}{m}} \;\; ; \;\; \lambda = \frac{h}{p} = \frac{h}{mv} = \frac{h}{m\sqrt{\dfrac{2eV}{m}}} = \frac{h}{\sqrt{2meV}} = \Delta x$$

$$\Delta x\Delta p = \frac{h}{2\pi} \quad \rightarrow \quad \Delta p = \frac{2\pi h}{\Delta x}$$

$$\frac{\Delta p_{\text{proton}}}{\Delta p_{\text{electron}}} = \frac{\dfrac{2\pi h}{\Delta x_{\text{proton}}}}{\dfrac{2\pi h}{\Delta x_{\text{electron}}}} = \frac{\Delta x_{\text{electron}}}{\Delta x_{\text{proton}}} = \frac{\dfrac{h}{\sqrt{2m_{\text{electron}}eV}}}{\dfrac{h}{\sqrt{2m_{\text{proton}}eV}}} = \sqrt{\frac{m_{\text{proton}}}{m_{\text{electron}}}} = \sqrt{\frac{1.67\times10^{-27}\,\text{kg}}{9.11\times10^{-31}\,\text{kg}}} = \boxed{43}$$

51. We use Eq. 37-10, Bohr's quantum condition.



$$mvr_n = n\frac{h}{2\pi} \quad \rightarrow \quad mvr_1 = \hbar \quad \rightarrow \quad mv = p = \frac{\hbar}{r_1} = \Delta p$$

$$\Delta x\Delta p \approx \hbar \quad \rightarrow \quad \Delta x \approx \frac{\hbar}{\Delta p} = \frac{\hbar}{\hbar/r_1} = r_1$$

The uncertainty in position is comparable to the Bohr radius.

52. (*a*) See the diagram.

(*b*) We use the solution $\psi(x) = Ae^{-Bx^2}$ in the Schrödinger equation.

$$\psi = Ae^{-Bx^2} \; ; \; \frac{d\psi}{dx} = -2ABxe^{-Bx^2}$$

$$\frac{d^2\psi}{dx^2} = -2ABe^{-Bx^2} - 2ABx\left(-2Bxe^{-Bx^2}\right)$$

$$= 2\left(2Bx^2 - 1\right)ABe^{-Bx^2}$$

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2} + U\Psi = -\frac{\hbar^2}{2m}\left[2\left(2Bx^2 - 1\right)ABe^{-Bx^2}\right] + \tfrac{1}{2}Cx^2Ae^{-Bx^2} = EAe^{-Bx^2} \quad \rightarrow$$

$$\left(\frac{\hbar^2 B}{m} - E\right) + \left(\tfrac{1}{2}C - \frac{2\hbar^2B^2}{m}\right)x^2 = 0$$

This is a solution if $\frac{\hbar^2 B}{m} = E$ and $\frac{1}{2}C = \frac{2\hbar^2B^2}{m}$. Solve these two equations for E in terms of C, and let $\omega \equiv \sqrt{C/m}$.

$$\tfrac{1}{2}C = \frac{2\hbar^2B^2}{m} \quad \rightarrow \quad B = \frac{\sqrt{mC}}{2\hbar} \; ; \; E = \frac{\hbar^2 B}{m} = \frac{\hbar^2}{m}\frac{\sqrt{mC}}{2\hbar} = \tfrac{1}{2}\hbar\sqrt{C/m} = \tfrac{1}{2}\hbar\omega$$

$$B = \frac{\sqrt{mC}}{2\hbar} = \frac{m}{2\hbar}\sqrt{C/m} = \frac{\omega m}{2\hbar}$$

53. We assume the alpha particle is in the ground state. The energy is given by Eq. 38-13.

$$E_1 = \frac{h^2}{8m\ell^2} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)^2}{8(4)\left(1.67\times10^{-27}\,\text{kg}\right)\left(1.5\times10^{-14}\,\text{m}\right)^2\left(1.60\times10^{-13}\,\text{J/MeV}\right)} = 0.2285\text{MeV}$$

$$\approx \boxed{0.23\text{MeV}}$$

The speed can be found from the kinetic energy. The alpha is non-relativistic.

$$E_1 = \frac{h^2}{8m\ell^2} = \tfrac{1}{2}mv^2 \quad \rightarrow \quad v = \frac{h}{2m\ell} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{2(4)\left(1.67\times10^{-27}\,\text{kg}\right)\left(1.5\times10^{-14}\,\text{m}\right)} = \boxed{3.3\times10^6\,\text{m/s}}$$

54. From energy conservation, the speed of a ball after falling a height H, or the speed needed to rise to a height H, is $v = \sqrt{2gH}$. We say that the starting height is H_0, and so the speed just before the ball hits the ground before the first bounce is $v_0 = \sqrt{2gH_0}$. After that bounce, the ball rebounded to $H_1 = 0.65H_0$, and so the speed right after the first bounce, and right before the second bounce, is $v_1 = \sqrt{2gH_1} = \sqrt{2g(0.65)H_0}$. Repeated application of this idea gives the maximum height after n bounces as $H_n = (0.65)^n H_0$, and the maximum speed after n bounces as $v_n = \sqrt{2g(0.65)^n H_0}$. The uncertainty principle will come into play in the problem when the maximum speed after a bounce is of the same order as the uncertainty in the speed. We take the maximum height as the uncertainty in the position.

$$m\Delta v_y = \Delta p_y \; ; \; \Delta y \Delta p_y \approx \hbar \quad \rightarrow \quad m\Delta v_y \approx \frac{\hbar}{\Delta y} \quad \rightarrow \quad mv_n \approx \frac{\hbar}{H_n} \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$m\sqrt{2g(0.65)^n H_0} \approx \frac{\hbar}{(0.65)^n H_0} \;\rightarrow\; 2m^2 g(0.65)^n H_0 \approx \frac{\hbar^2}{(0.65)^{2n} H_0^2} \;\rightarrow$$

$$(0.65)^{3n} \approx \frac{\hbar^2}{2m^2 g H_0^3} \;\rightarrow\; n \approx \frac{\ln\left(\dfrac{\hbar^2}{2m^2 g H_0^3}\right)}{3\ln(0.65)} = \frac{\ln\left[\dfrac{(1.055\times10^{-34}\,\text{J•s})^2}{2(3.0\times10^{-6}\,\text{kg})^2(9.80\,\text{m/s}^2)(2.0\,\text{m})^3}\right]}{3\ln(0.65)} = \boxed{105}$$

After about 105 bounces, the uncertainty principle will be important to consider.

55. We model the electrons as being restricted from leaving the surface of the sodium by an energy barrier, similar to Figure 38-15a. The difference between the barrier's height and the energy of the electrons is the work function, and so $U_0 - E = W_0 = 2.28\,\text{eV}$. But quantum mechanically, some electrons will "tunnel" through that barrier without ever being given the work function energy, and thus get outside the barrier, as shown in Figure 38-15b. This is the tunneling current as indicated in Figure 38-18. The distance from the sodium surface to the tip of the microscope is the width of the barrier, ℓ. We calculate the transmission probability as a function of barrier width by Eqs. 38-17a and 38-17b. The barrier is then increased to $\ell + \Delta\ell$, which will lower the transmission probability.

$$2G\Delta\ell = 2\Delta\ell\frac{\sqrt{2m(U_0 - E)}}{\hbar} = 2(0.02\times10^{-9}\,\text{m})\frac{\sqrt{2(9.11\times10^{-31}\,\text{kg})(2.28\,\text{eV})(1.60\times10^{-19}\,\text{J/eV})}}{(1.055\times10^{-34}\,\text{J•s})}$$

$$= 0.3091$$

$$T_0 = e^{-2G\ell}\;;\; T = e^{-2G(\ell+\Delta\ell)}\;;\; \frac{T}{T_0} = \frac{e^{-2G(\ell+\Delta\ell)}}{e^{-2G\ell}} = e^{-2G\Delta\ell} = e^{-0.3091} = 0.734$$

The tunneling current is caused by electrons that tunnel through the barrier. Since current is directly proportional to the number of electrons making it through the barrier, any change in the transmission probability is reflected as a proportional change in current. So we see that the change in the transmission probability, which will be reflected as a change in current, is a decrease of 27%. Note that this change is only a fraction of the size of an atom.

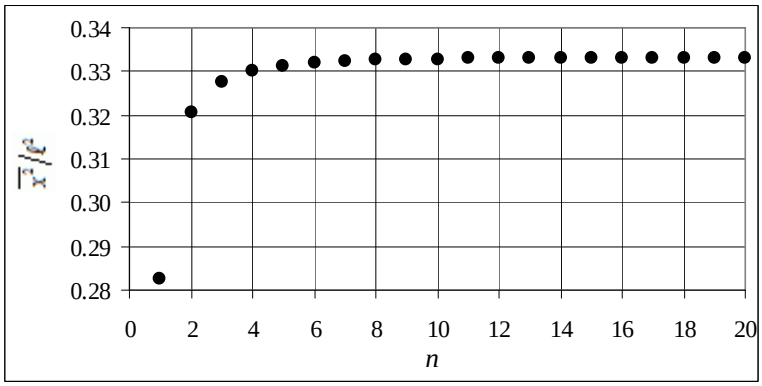
56. The time independent Schrödinger equation with $U = 0$ is $-\dfrac{\hbar^2}{2m}\dfrac{d^2\psi}{dx^2} = E\psi$.

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2} = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2}\left(Ae^{ikx}\right) = -\frac{\hbar^2}{2m}\left(-k^2\right)Ae^{ikx} = \frac{\hbar^2k^2}{2m}\psi = \frac{\hbar^2\left(\sqrt{\dfrac{2mE}{\hbar}}\right)^2}{2m}\psi = E\psi$$

We see that the function solves the Schrödinger equation.

57. The wave functions for the particle in the infinite well are $\psi_n = \sqrt{\dfrac{2}{\ell}}\sin\left(\dfrac{n\pi}{\ell}x\right)$, as derived in Section 38-8. A table of integrals was consulted to find $\int x^2\left(\sin^2 ax\right)dx$.

$$\overline{x^2} = \int x^2|\psi_n|^2\,dx = \int_0^\ell x^2\left[\sqrt{\frac{2}{\ell}}\sin\left(\frac{n\pi}{\ell}x\right)\right]^2 dx = \frac{2}{\ell}\int_0^\ell x^2\sin^2\left(\frac{n\pi}{\ell}x\right)dx$$



Note that $\int x^2\left(\sin^2 ax\right)dx = \dfrac{x^3}{6} - \left(\dfrac{x^2}{4a} - \dfrac{1}{8a^3}\right)\sin 2ax - \dfrac{x\cos 2ax}{4a^2}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\overline{x^2} = \frac{2}{\ell}\int_0^{\ell} x^2 \sin^2\left(\frac{n\pi}{\ell}x\right)dx = \frac{2}{\ell}\left\{\frac{x^3}{6} - \left(\frac{x^2}{4\frac{n\pi}{\ell}} - \frac{1}{8\left(\frac{n\pi}{\ell}\right)^3}\right)\sin\left(\frac{2n\pi}{\ell}x\right) - \frac{x\cos\left(\frac{2n\pi}{\ell}x\right)}{4\left(\frac{n\pi}{\ell}\right)^2}\right\}_0^{\ell}$$

$$= \boxed{\ell^2\left[\tfrac{1}{3} - \tfrac{1}{2}(n\pi)^{-2}\right]}$$

See the adjacent graph. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH38.XLS," on tab "Problem 38.57."

58. (*a*) To check that the wave function is normalized, we calculate $\int_{-\infty}^{\infty} |\psi(x)|^2\,dx$.

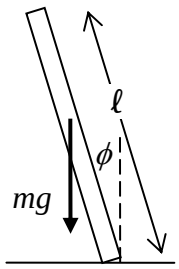
$$\int_{-\infty}^{\infty} |\psi(x)|^2\,dx = \int_{-\infty}^{\infty} \frac{1}{b}\left|\frac{x}{b}\right| e^{-\frac{x^2}{b^2}}dx = \frac{2}{b^2}\int_0^{\infty} x e^{-\frac{x^2}{b^2}}dx = \frac{2}{b^2}\left[-\frac{b^2}{2}e^{-\frac{x^2}{b^2}}\right]_0^{\infty} = -(0-1) = 1$$

We see that the function is normalized.

(*b*) The most probable position is that for which $|\psi(x)|^2$ is maximized. That point can be found by solving $\frac{d|\psi(x)|^2}{dx} = 0$ for *x*. Since we are only considering $x > 0$, we need not use the absolute value signs in the function.

$$\frac{d|\psi(x)|^2}{dx} = \frac{d\left[\frac{x}{b^2}e^{-\frac{x^2}{b^2}}\right]}{dx} = \frac{1}{b^2}e^{-\frac{x^2}{b^2}} + \frac{x}{b^2}\left(-\frac{2x}{b^2}\right)e^{-\frac{x^2}{b^2}} = 0 \;\rightarrow\; 1 = \frac{2x^2}{b^2} \;\rightarrow$$

$$x = \frac{b}{\sqrt{2}} = \frac{1.0\,\text{nm}}{\sqrt{2}} = \boxed{0.71\text{nm}}$$



This value for *x* maximizes the function, because the function must be positive, and the function is 0 at $x = 0$ and $x = \infty$. Thus this single local extreme point must be a maximum.

(*c*) To find the probability, we integrate the probability density function between the given limits.

$$P = \int_0^{0.50\,\text{nm}} |\psi(x)|^2\,dx = \int_0^{0.50\,\text{nm}} \frac{x}{b^2}e^{-\frac{x^2}{b^2}}dx = \left[-\tfrac{1}{2}e^{-\frac{x^2}{b^2}}\right]_0^{0.50\,\text{nm}} = \left(-\tfrac{1}{2}e^{-0.25}\right) - \left(-\tfrac{1}{2}\right) = \boxed{0.11}$$

59. (*a*) We assume the pencil is a uniform rod, and that it makes an angle of ϕ with the vertical. If the bottom point is fixed, then the torque due to its weight about the bottom point will cause an angular acceleration. See the diagram.

$$\tau = I\alpha \quad \rightarrow \quad mg\left(\tfrac{1}{2}\ell\right)\sin\phi = \tfrac{1}{3}m\ell^2\frac{d^2\phi}{dt^2}$$

From the equation, if the pencil is exactly upright, so that $\phi = 0,$ then the angular acceleration will be exactly 0 and the pencil will remain stationary. But according to the uncertainty principle (as expressed at the bottom of page 1023), the angle cannot be known with 0 uncertainty. Let the *z* axis be coming out of the page.

$$\Delta L_z \Delta\phi \geq \hbar \quad \rightarrow \quad \Delta\phi \geq \frac{\hbar}{\Delta L_z} > 0$$

Thus the pencil cannot have exactly $\phi = 0,$ and so there will be a torque and hence rotation.

(*b*) For the initial part of the motion, the angle will be very small, and so the differential equation can be expressed as $\frac{3g}{2\ell}\phi = \frac{d^2\phi}{dt^2}.$ The solutions to this differential equation are of the form $\phi = Ae^{kt} + Be^{-kt},$ where $k = \sqrt{\frac{3g}{2\ell}} = \sqrt{\frac{3\left(9.80\,\text{m/s}^2\right)}{2\left(0.18\,\text{m}\right)}} = 9.037\,\text{s}^{-1}$ Since the angle will be increasing in time, we ignore the second term, which decreases in time. Thus $\phi \approx Ae^{kt},$ with $\phi\left(t=0\right) = \phi_0 \approx A.$ The angular velocity of the pencil is approximated as $\omega = \frac{d\phi}{dt} = kAe^{kt},$ and the initial angular velocity is $\omega_0 = kA.$ We take the initial position and the initial angular velocity as their smallest possible values, which are their uncertainties – the magnitude of a quantity must be at least as big as its uncertainties. Apply the uncertainty principle in angular form.

$$\Delta L_z \Delta\phi \geq \hbar \quad \rightarrow \quad \left(I\Delta\omega\right)\Delta\phi = \tfrac{1}{3}m\ell^2\left(kA\right)\left(A\right) = \tfrac{1}{3}m\ell^2 kA^2 \geq \hbar \quad \rightarrow$$

$$A \geq \sqrt{\frac{3\hbar}{m\ell^2 k}} = \sqrt{\frac{3\left(1.055\times10^{-34}\,\text{J•s}\right)}{\left(7.0\times10^{-3}\,\text{kg}\right)\left(0.18\,\text{m}\right)^2\left(9.037\,\text{s}^{-1}\right)}} = 3.930\times10^{-16}\,\text{rad} = \phi_0$$

$$\omega_0 = kA = \left(9.037\,\text{s}^{-1}\right)\left(3.930\times10^{-16}\,\text{rad}\right) = 3.552\times10^{-15}\,\text{rad/s}$$

With this initial position and initial angular velocity, we can then do a numeric integration to find the time when the angle is $\phi = \pi/2\,\text{rad}.$ For a step size of 0.01 s, the time of fall is about 4.07 s. For a step size of 0.001 s, the time of fall is about 3.99 s. This is only about a 2% change in the final result, so the time is pretty stable around 4 s. Even changing the starting angle to a value 100 times bigger than that above (so $\phi_0 = 3.930\times10^{-14}\,\text{rad}$) still gives a time of fall of 3.48 s. So within a factor of 2, we estimate the time of fall as 4 seconds.

Note that if the solution of the approximate differential equation is used, $\phi \approx Ae^{kt},$ we get the following time of fall.

$$t_{\max} = \frac{1}{k}\ln\left(\frac{\phi_{\max}}{A}\right) = \frac{1}{9.037\,\text{s}^{-1}}\ln\left(\frac{\pi/2}{3.930\times10^{-16}}\right) = 3.98\,\text{s}.$$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH38.XLS," on tab "Problem 38.59."

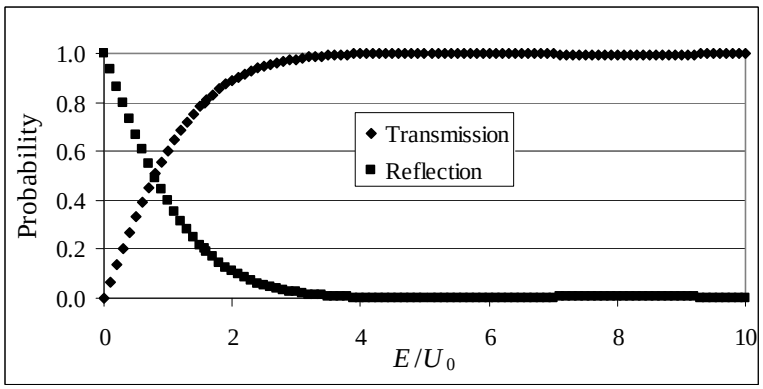
60. The ground state wave function for the particle in the infinite well is $\psi = \sqrt{\frac{2}{\ell}}\sin\left(\frac{\pi}{\ell}x\right)$. Let $x_{\text{center}} = \frac{1}{2}\ell$, so the region of interest extends from $x_{\min} = \frac{1}{2}\ell - \frac{1}{2}\Delta x$ to $x_{\max} = \frac{1}{2}\ell + \frac{1}{2}\Delta x$. We are to find the largest value of Δx so that the approximate probability of $\left|\psi\left(x = \frac{1}{2}\ell\right)\right|^2 \Delta x = \frac{2\Delta x}{\ell}$ (from Example 38-7) is no more than 10% different than $\int_{x_{\min}}^{x_{\max}} \left[\sqrt{\frac{2}{\ell}}\sin\left(\frac{\pi}{\ell}x\right)\right]^2 dx$, the exact probability.



We calculate the value of the integral using numeric integration (as described in Section 2-9), first finding the number of steps needed between $x_{\min}$ and $x_{\max}$ that gives a stable value. Then we compare the integral to the approximation. (Note that the integral could be evaluated exactly.) To aid in the evaluation of the integral, we make the substitution that $u = x/\ell$. Then the integral becomes as follows.

$$\int_{u_{\min}=\frac{1}{2}\left(1-\frac{\Delta x}{\ell}\right)}^{u_{\max}=\frac{1}{2}\left(1-\frac{\Delta x}{\ell}\right)} \left[2\sin^2(\pi u)\right] du$$

In doing the numeric integrations, we found that for any value of Δx up to ℓ, breaking the numeric integration up into 50 steps gave the same answer to 3 significant digits as breaking it up into 100 steps. So we did all numeric integrations with 50 steps. We then numerically calculated the integral for values of $\Delta x/\ell$, starting at 0.01, and increasing by steps of 0.01, until we found a 10% difference between the approximation and the numeric integration. This happens at $\Delta x/\ell = 0.34$, and so the approximation is good within 10% up to $\Delta x = 0.34\ell = 0.34(0.10\,\text{nm}) = \boxed{0.034\,\text{nm}}$. This is much broader than we might have guessed initially, indicating that the wave function is varying rather slowly over the central region of the potential well. The spreadsheet used for this problem can be found on the Media Manager, with filename"PSE4_ISM_CH38.XLS," on tab "Problem 38.60."

61. (*a*) See the graph.
(*b*) From the graph and the spreadsheet, we find these results.

$T = 10\%$ at $E/U_0 = 0.146$
$T = 20\%$ at $E/U_0 = 0.294$
$T = 50\%$ at $E/U_0 = 0.787$
$T = 80\%$ at $E/U_0 = 1.56$

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH38.XLS," on tab "Problem 38.61."

CHAPTER 39: Quantum Mechanics of Atoms

Responses to Questions

1. The Bohr model placed electrons in definite circular orbits described by a single quantum number (n). The Bohr model could not explain the spectra of atoms more complex than hydrogen and could not explain fine structure in the spectra. The quantum-mechanical model uses the concept of electron "probability clouds," with the probability of finding the electron at a given position determined by the wave function. The quantum model uses four quantum numbers to describe the electron (n, ℓ, m_ℓ, m_s) and can explain the spectra of more complex atoms and fine structure.

2. The quantity $|\psi|^2$ is maximum at $r = 0$ because of its dependence on the factor e^{-r/r_0}. In the ground state, the electron is expected to be found near the nucleus. The radial probability density $4\pi r^2 |\psi|^2$ gives the probability of finding the electron in a thin spherical shell located at r. Since $r = 0$ is at the center of the nucleus, the radial probability density is zero here.

3. The quantum-mechanical model predicts that the electron spends more time near the nucleus. In the Bohr model, the electron in the ground state is in a fixed orbit of definite radius. The electron cannot come any closer to the nucleus than that distance. In the quantum-mechanical model, the electron is most often found at the Bohr radius, but it can also be found closer to the nucleus (and farther away).

4. As the number of electrons goes up, the number of protons in the nucleus increases, which increases the attraction of the electrons to the center of the atom. Even though the outer electrons are partially screened from the increased nuclear charge by the inner electrons, they are all pulled closer to the more positive nucleus. Also, more states are available in the upper shells to accommodate many more electrons at approximately the same radius.

5. Because the nuclei of hydrogen and helium are different, the energy levels of the atoms are different. The presence of the second electron in helium will also affect its energy levels. If the energy levels are different, then the energy difference between the levels will be different and the spectra will be different.

6. The two levels have different orbital quantum numbers. The orbital quantum number for the upper level is $\ell = 2$. This results in five different possible values of m_ℓ (–2, –1, 0, 1, and 2) so the energy level is split into five separate levels in the presence of a magnetic field. The lower level shown has an orbital quantum number of $\ell = 1$, so only three different values of m_ℓ (–1, 0 and 1) are possible, and therefore the energy level is split into only three separate levels.

7. In the time-independent Schrödinger equation, the wave function and the potential depend on the three spatial variables. The three quantum numbers result from application of boundary conditions to the wave function.

8. The Zeeman effect is the splitting of an energy level in the presence of a magnetic field. In the reference frame of the electron, the nucleus orbits the electron. The "internal" Zeeman effect, as seen in sodium, is caused by the magnetic field produced by the "orbiting" nucleus.

9. (*a*) and (*c*) are allowed for atoms in an excited state. (*b*) is not allowed. Only six electrons are allowed in the 2*p* state.

10. The complete electron configuration for a uranium atom is as follows.
$1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 4f^{14} 5s^2 5p^6 5d^{10} 5f^3 6s^2 6p^6 6d^1 7s^2$

11. (*a*) Group II; (*b*) Group VIII; (*c*) Group I; (*d*) Group VII.

12. The periodicity of the periodic table depends on the number and arrangements of the electrons in the atom. It therefore depends on all the factors which determine this arrangement. One of these, the Pauli exclusion principle, states that no two electrons can occupy the same quantum state. The number of electrons that can be in any principle state depends on how many different substates are available, which is determined by the number of possible orbital quantum numbers for each principle state, the number of possible magnetic quantum numbers for each orbital quantum number, and finally, the number of spin orientations for each electron. Therefore, quantization of angular momentum, direction of angular momentum, and spin all play a role in the periodicity of the periodic table. (See Table 39-1 for a summary of the quantum numbers.)

13. If there were no electron spin, then, according to the Pauli exclusion principle, *s*-subshells would be filled with one electron, *p*-subshells with three electrons, and *d*-subshells with five electrons. The first 20 elements of the periodic table would look like the following:

H 1 $1s^1$								
He 2 $2s^1$						Li 3 $2p^1$	Be 4 $2p^2$	B 5 $2p^3$
C 6 $3s^1$						N 7 $3p^1$	O 8 $3p^2$	F 9 $3p^3$
Ne 10 $4s^1$	Na 11 $3d^1$	Mg 12 $3d^2$	Al 13 $3d^3$	Si 14 $3d^4$	P 15 $3d^5$	S 16 $4p^1$	Cl 17 $4p^2$	Ar 18 $4p^3$
K 19 $5s^1$	Ca 20 $4d^1$							

14. Neon is a noble gas and does not react readily with other elements. Neon has its outermost subshell completely filled, and so the electron distribution is spherically symmetric, making it harder to remove an electron. Sodium is in the first column of the periodic table and is an alkali metal. Sodium has a single outer *s* electron, which is outside the inner closed shells and shielded from the nuclear charge by the inner electrons, making it easier to remove. Therefore, neon has a higher ionization energy than sodium, even though they differ in number of protons by only one.

15. Chlorine and iodine are in the same column of the periodic table. They are each one electron away from having a complete outermost shell and will react readily with atoms having only one electron in the outermost shell. Interactions with other atoms depend largely on the outermost electrons; therefore these two elements will have similar properties because their outermost electrons are in similar configurations.

16. Potassium and sodium are in the same column of the periodic table. They each have only one electron in the outermost shell, and their inner shells are completely filled. Sodium has only one electron in the $n = 3$ shell, or principle energy level, and potassium has only one electron in the $n = 4$ level. Interactions with other atoms depend largely on the outermost electrons, and therefore these two elements will have similar properties because their outermost electrons are in similar configurations.

17. Rare earth elements have similar chemical properties because the electrons in the filled 6*s* or 7*s*-suborbitals serve as the valence electrons for all these elements. They all have partially filled inner *f*-suborbitals, which are very close together in energy. The different numbers of electrons in the *f*-suborbitals have very little effect on the chemical properties of these elements.

18. When we use the Bohr theory to calculate the X-ray line wavelengths, we estimate the nuclear charge seen by the transitioning electron as $Z - 1$, assuming that the second electron in the ground state is partially shielding the nuclear charge. This is only an estimate, so we do not expect the calculated wavelengths to agree exactly with the measured values.

19. In helium and other complex atoms, electrons interact with other electrons in addition to their interactions with the nucleus. The Bohr theory only works well for atoms that have a single outer electron in an *s* state. X-ray emissions generally involve transitions to the 1*s* or 2*s* states. In these cases the Bohr theory can be modified to correct for screening from a second electron by using the factor $Z - 1$ for the nuclear charge and can yield good estimates of the transition energies. Transitions involving outer electrons in more complex atoms will be affected by additional complex screening effects and cannot be adequately described by the Bohr theory.

20. The continuous portion of the X-ray spectrum is due to the "bremsstrahlung" radiation. An incoming electron gives up energy in the collision and emits light. Electrons can give up all or part of their kinetic energy. The maximum amount of energy an electron can give up is its total amount of kinetic energy. In the photon description of light, the maximum electron kinetic energy will correspond to the energy of the shortest wavelength (highest energy) photons that can be produced in the collisions. The result is the existence of "cut-off" wavelength in the X-ray spectrum. An increase in the number of electrons will not change the cut-off wavelength. According to wave theory, an increase in the number of electrons could result in the production of shorter-wavelength photons, which is not observed experimentally.

21. To figure out which lines in an X-ray spectrum correspond to which transitions, you would use the Bohr model to estimate the energies of the transitions between levels and match these to the energies of the observed lines. The energies of transitions to the $n = 1$ level (K) will be the greatest, followed by the transitions to the $n = 2$ level (L). Within a level, the α line will have the lowest energy (because it corresponds to a transition between adjacent levels), followed by the β line, and so on.

22. The characteristic X-ray spectra occur when inner electrons are knocked out of their shells. X-rays are the high energy photons emitted when other electrons fall to replace the knocked-out electrons. Because the shells involved are close to the nucleus, Z will have a direct influence on the energies. The visible spectral lines due to transitions between upper levels have energies less influenced by Z because the inner electrons shield the outer electrons from the nuclear charge.

23. The difference in energy between adjacent energy levels in an atom decreases with increasing *n*. Therefore, transitions of electrons between inner energy levels will produce higher energy (shorter wavelength) photons than transitions between outer energy levels.

24. The electron has a negative charge.

25. Consider a silver atom in its ground state for which the entire magnetic moment is due to the spin of only one of its electrons. In a uniform magnetic field, the dipole will experience a torque that would tend to align it with the field. In a non-uniform field, each pole of the dipole will experience a force of different magnitude. Consequently, the dipole will experience a net force that varies with the spatial orientation of the dipole. The Stern-Gerlach experiment provided the first evidence of space

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

quantization, since it clearly indicated that there are two opposite spin orientations for the outermost electron in the silver atom.

26. Spontaneous emission occurs randomly when an electron in an excited state falls to a lower energy level and emits a photon. Stimulated emission also results when an electron falls to a lower energy level, but it occurs when a photon of the same energy as the transition stimulates the electron to fall sooner than it would have naturally.

27. No. The intensity of a spherical wave, which spreads out in all directions, follows the inverse-square law. A laser produces light that is very nearly a plane wave; its intensity is nearly constant with distance.

28. Laser light is monochromatic, coherent, and in a narrow beam that spreads very little if at all. Ordinary light is usually made up of many different wavelengths, incoherent, and spreads out in all directions. Both types of light can be created when electrons fall to lower energy levels and emit photons.

29. Since laser light is a plane wave, its intensity remains approximately constant with distance. The light produced by a street lamp spreads out with an intensity that decreases as $1/r^2$. Thus, at a sufficient distance, the laser light will be more intense than the light from a street lamp.

Solutions to Problems

1. The value of ℓ can range from 0 to $n-1$. Thus for $n = 7$, $\boxed{\ell = 0, 1, 2, 3, 4, 5, 6}$.

2. The value of m_ℓ can range from $-\ell$ to $+\ell$. Thus for $\ell = 3$, $\boxed{m_\ell = -3, -2, -1, 0, 1, 2, 3}$.
   The possible values of m_s are $\boxed{-\tfrac{1}{2}, +\tfrac{1}{2}}$.

3. The value of ℓ ranges from 0 to $n-1$. Thus for $n = 3$, $\ell = 0,1,2$. For each ℓ the value of m_ℓ can range from $-\ell$ to $+\ell$, or $2\ell+1$ values. For each m_ℓ there are 2 values of m_s. Thus the number of states for each ℓ is $2(2\ell+1)$. The number of states is $N = 2(0+1) + 2(2+1) + 2(4+1)$
   $= \boxed{18 \text{ states}}$. We start with $\ell = 0$, and list the quantum numbers in the order (n, ℓ, m_ℓ, m_s).

   $\boxed{\begin{array}{l}(3, 0, 0, -\tfrac{1}{2}), (3, 0, 0, +\tfrac{1}{2}), (3, 1, -1, -\tfrac{1}{2}), (3, 1, -1, +\tfrac{1}{2}), (3, 1, 0, -\tfrac{1}{2}), (3, 1, 0, +\tfrac{1}{2}),\\ (3, 1, 1, -\tfrac{1}{2}), (3, 1, 1, +\tfrac{1}{2}), (3, 2, -2, -\tfrac{1}{2}), (3, 2, -2, +\tfrac{1}{2}), (3, 2, -1, -\tfrac{1}{2}), (3, 2, -1, +\tfrac{1}{2}),\\ (3, 2, 0, -\tfrac{1}{2}), (3, 2, 0, +\tfrac{1}{2}), (3, 2, 1, -\tfrac{1}{2}), (3, 2, 1, +\tfrac{1}{2}), (3, 2, 2, -\tfrac{1}{2}), (3, 2, 2, +\tfrac{1}{2})\end{array}}$

4. The value of m_ℓ can range from $-\ell$ to $+\ell$, so we have $\boxed{\ell \geq 4}$.
   The value of ℓ can range from 0 to $n-1$. Thus we have $\boxed{n \geq \ell + 1(\text{minimum } 5)}$.
   There are two values of m_s: $\boxed{m_s = -\tfrac{1}{2}, +\tfrac{1}{2}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

5. The value of ℓ can range from 0 to $n-1$. Thus for $\ell = 5$, we have $\boxed{n \geq 6}$.
For each ℓ the value of m_ℓ can range from $-\ell$ to $+\ell$: $\boxed{m_\ell = -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5}$.
There are two values of m_s: $\boxed{m_s = -\tfrac{1}{2}, +\tfrac{1}{2}.}$

6. The magnitude of the angular momentum depends only on ℓ.
$$L = \sqrt{\ell(\ell+1)}\hbar = \boxed{\sqrt{12}\hbar} = \sqrt{12}\left(1.055\times10^{-34}\ \text{J•s}\right) = \boxed{3.65\times10^{-34}\ \text{J•s}}$$

7. (*a*) The principal quantum number is $n = \boxed{7}$.
(*b*) The energy of the state is
$$E_7 = -\frac{(13.6\text{eV})}{n^2} = -\frac{(13.6\text{eV})}{7^2} = \boxed{-0.278\text{eV}}.$$
(*c*) The "*g*" subshell has $\ell = \boxed{4}$. The magnitude of the angular momentum depends on ℓ only:
$$L = \hbar\sqrt{\ell(\ell+1)} = \boxed{\sqrt{20}\hbar} = \sqrt{20}\left(1.055\times10^{-34}\ \text{J•s}\right) = \boxed{4.72\times10^{-34}\ \text{J•s}}$$
(*d*) For each ℓ the value of m_ℓ can range from $-\ell$ to $+\ell$: $\boxed{m_\ell = -4, -3, -2, -1, 0, 1, 2, 3, 4}$.

8. (*a*) For each ℓ the value of m_ℓ can range from $-\ell$ to $+\ell$, or $2\ell+1$ values. For each of these there are two values of m_s. Thus the total number of states in a subshell is $N = \boxed{2(2\ell+1)}$.
(*b*) For $\ell = 0$, 1, 2, 3, 4, 5, and 6, $N = \boxed{2, 6, 10, 14, 18, 22, \text{and } 26}$, respectively.

9. For a given *n*, $0 \leq \ell \leq n-1$. Since for each ℓ the number of possible states is $2(2\ell+1)$, the number of possible states for a given *n* is as follows.
$$\sum_{\ell=0}^{n-1} 2(2\ell+1) = 4\sum_{\ell=0}^{n-1}\ell + \sum_{\ell=0}^{n-1} 2 = 4\left(\frac{n(n-1)}{2}\right) + 2n = \boxed{2n^2}$$

10. Photon emission means a jump to a lower state, so for the final state, *n* = 1, 2, 3, or 4. For a *d* subshell, $\ell = 2$, and because $\Delta\ell = \pm 1$, the new value of ℓ must be 1 or 3.
(*a*) $\ell = 1$ corresponds to a *p* subshell, and $\ell = 3$ corresponds to an *f* subshell. Keeping in mind that $0 \leq \ell \leq n-1$, we find the following possible destination states: $2p, 3p, 4p, 4f$.
(*b*) In a hydrogen atom, ℓ has no appreciable effect on energy, and so for energy purposes there are four possible destination states, corresponding to *n* = 2, 3, and 4. Thus there are $\boxed{\text{three different}}$ $\boxed{\text{photon wavelengths}}$ corresponding to three possible changes in energy.

11. We use Eq. 39-3 to find ℓ and Eq. 39-4 to find m_ℓ.
$$L = \sqrt{\ell(\ell+1)}\hbar \ \rightarrow\ \ell(\ell+1) = \frac{L^2}{\hbar^2} = \frac{\left(6.84\times10^{-34}\text{J•s}\right)^2}{\left(1.055\times10^{-34}\text{J•s}\right)^2} = 42 \ \rightarrow\ \boxed{\ell = 6}$$
$$L_z = m_\ell\hbar \ \rightarrow\ m_\ell = \frac{L_z}{\hbar} = \frac{2.11\times10^{-34}\text{J•s}}{1.055\times10^{-34}\text{J•s}} = \boxed{2}$$
Since $\ell = 6$, we must have $\boxed{n \geq 7}$.

12. To show that the ground-state wave function is normalized, we integrate $|\psi_{100}|^2$ over all space. Use substitution of variables and an integral from Appendix B-5.

$$\int_{\text{all space}} |\psi_{100}|^2\, dV = \int_0^\infty \frac{1}{\pi r_0^3} e^{-\frac{2r}{r_0}} 4\pi r^2 dr\ ; \quad \text{let } x = \frac{2r}{r_0} \ \rightarrow\ r = \tfrac{1}{2} r_0 x\ ,\ dr = \tfrac{1}{2} r_0 dx$$

Note that if $r = 0, x = 0$ and if $r = \infty, x = \infty$.

$$\int_{\text{all space}} |\psi_{100}|^2\, dV = \int_0^\infty \frac{1}{\pi r_0^3} e^{-\frac{2r}{r_0}} 4\pi r^2 dr = \frac{4\pi}{\pi r_0^3} \int_0^\infty e^{-x} \left(\tfrac{1}{4} r_0^2 x^2\right)\left(\tfrac{1}{2} r_0 dx\right) = \tfrac{1}{2} \int_0^\infty e^{-x} x^2 dx = \tfrac{1}{2}(2!) = 1$$

And so we see that the ground-state wave function is normalized.

13. The ground state wave function is $\psi_{100} = \dfrac{1}{\sqrt{\pi r_0^3}} e^{-r/r_0}$.

(*a*) $\left(\psi_{100}\right)_{r=1.5r_0} = \boxed{\dfrac{1}{\sqrt{\pi r_0^3}} e^{-1.5}}$

(*b*) $\left(|\psi_{100}|^2\right)_{r=1.5r_0} = \boxed{\dfrac{1}{\pi r_0^3} e^{-3}}$

(*c*) $P_{\text{r}} = \left(4\pi r^2 |\psi_{100}|^2\right)_{r=1.5r_0} = 4\pi r_0^2 \left(\dfrac{1}{\pi r_0^3} e^{-2}\right) = \boxed{\dfrac{4}{r_0} e^{-3}}$

14. The state $n = 2, \ell = 0$ must have $m_\ell = 0$ and so the wave function is $\psi_{200} = \dfrac{1}{\sqrt{32\pi r_0^3}} \left(2 - \dfrac{r}{r_0}\right) e^{-\frac{r}{2r_0}}$.

(*a*) $\left(\psi_{200}\right)_{r=4r_0} = \dfrac{1}{\sqrt{32\pi r_0^3}} \left(2 - \dfrac{4r_0}{r_0}\right) e^{-\frac{4r_0}{2r_0}} = \boxed{-\dfrac{1}{\sqrt{8\pi r_0^3}} e^{-2}}$

(*b*) $\left(|\psi_{200}|^2\right)_{r=4r_0} = \dfrac{1}{32\pi r_0^3} \left(2 - \dfrac{4r_0}{r_0}\right)^2 e^{-2\frac{4r_0}{2r_0}} = \boxed{\dfrac{1}{8\pi r_0^3} e^{-4}}$

(*c*) $P_{\text{r}} = \left(4\pi r^2 |\psi_{200}|^2\right)_{r=4r_0} = 4\pi (4r_0)^2 \left(\dfrac{1}{8\pi r_0^3} e^{-4}\right) = \boxed{\dfrac{8}{r_0} e^{-4}}$

15. The factor is found from the ratio of the radial probability densities for ψ_{100}. Use Eq. 39-7.

$$\frac{P_{\text{r}}(r = r_0)}{P_{\text{r}}(r = 2r_0)} = \frac{\left(4\dfrac{r^2}{r_0^2} e^{-\frac{2r}{r_0}}\right)_{r=r_0}}{\left(4\dfrac{r^2}{r_0^2} e^{-\frac{2r}{r_0}}\right)_{r=2r_0}} = \frac{\left(4\dfrac{r_0^2}{r_0^2} e^{-\frac{2r_0}{r_0}}\right)_{r=r_0}}{\left(4\dfrac{(2r_0)^2}{r_0^2} e^{-\frac{2(2r_0)}{r_0}}\right)_{r=2r_0}} = \frac{e^{-2}}{4e^{-4}} = \boxed{\frac{e^2}{4}} \approx 1.85$$

16. (*a*) To find the probability, integrate the radial probability distribution for the ground state. We follow Example 39-4, and use the last integral in Appendix B-4.

$$\text{P} = \int_0^{r_0} 4\frac{r^2}{r_0^3} e^{-\frac{2r}{r_0}} dr\ ; \text{ let } x = 2\frac{r}{r_0} \ \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\mathrm{P} = \tfrac{1}{2}\int_0^2 x^2 e^{-x}dx = \tfrac{1}{2}\left[-e^{-x}\left(x^2+2x+2\right)\right]_0^2 = 1-5e^{-2} = 0.32 = \boxed{32\%}$$

(*b*) We follow the same process here.

$$\mathrm{P} = \int_{r_0}^{2r_0} 4\frac{r^2}{r_0^3}e^{-\frac{2r}{r_0}}dr \text{ ; let } x = 2\frac{r}{r_0} \rightarrow$$

$$\mathrm{P} = \tfrac{1}{2}\int_2^4 x^2 e^{-x}dx = \tfrac{1}{2}\left[-e^{-x}\left(x^2+2x+2\right)\right]_2^4 = 5e^{-2}-13e^{-4} = 0.44 = \boxed{44\%}$$

17. To find the probability for the electron to be within a sphere of radius *r*, we must integrate the radial probability density for the ground state from 0 to *r*. The density is given in Eq. 39-7.

$$\mathrm{P} = \int_0^{r_{\text{sphere}}} 4\frac{r^2}{r_0^3}e^{-\frac{2r}{r_0}}dr \text{ ; let } x' = 2\frac{r}{r_0} \text{ ; let } 2\frac{r_{\text{sphere}}}{r_0} = x \rightarrow$$

$$\mathrm{P} = \tfrac{1}{2}\int_0^x x'^2 e^{-x'}dx' = \tfrac{1}{2}\left[-e^{-x'}\left(x'^2+2x'+2\right)\right]_0^x = \tfrac{1}{2}\left\{\left[-e^{-x}\left(x^2+2x+2\right)\right]+2\right\} = 1-e^{-x}\left(\tfrac{1}{2}x^2+x+1\right)$$

We solve this equation numerically for values of *x* that give P = 0.50, 0.90, and 0.99.

(*a*) The equation for P = 0.50 is solved by $x = 2.674$, and so $r_{\text{sphere}} = \tfrac{1}{2}(2.674)r_0 \approx \boxed{1.3r_0}$.

(*b*) The equation for P = 0.90 is solved by $x = 5.322$, and so $r_{\text{sphere}} = \tfrac{1}{2}(5.322)r_0 \approx \boxed{2.7r_0}$.

(*c*) The equation for P = 0.99 is solved by $x = 8.406$, and so $r_{\text{sphere}} = \tfrac{1}{2}(8.406)r_0 \approx \boxed{4.2r_0}$.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH39.XLS," on tab "Problem 39.17."

18. (*a*) To find the probability for the electron to be within a sphere of radius *r*, we must integrate the radial probability density for the ground state from 0 to *r*. The density is given in Eq. 39-7. Since $r \ll r_0$, we approximate $e^{-2r/r_0} \approx 1$.

$$\mathrm{P} = \int_0^{1.1\text{fm}} 4\frac{r^2}{r_0^3}e^{-\frac{2r}{r_0}}dr \approx \int_0^{1.1\text{fm}} 4\frac{r^2}{r_0^3}dr = \frac{4}{3}\frac{r^3}{r_0^3} = \frac{4}{3}\frac{\left(1.1\times10^{-15}\text{m}\right)^3}{\left(0.529\times10^{-10}\text{m}\right)^3} = \boxed{1.2\times10^{-14}}$$

(*b*) The Bohr radius, r_0, is inversely proportional to the mass of the particle. So now the Bohr radius is smaller by a factor of 207.

$$\mathrm{P} = \int_0^{1.1\text{fm}} 4\frac{r^2}{r_0^3}e^{-\frac{2r}{r_0}}dr \approx \int_0^{1.1\text{fm}} 4\frac{r^2}{r_0^3}dr = \frac{4}{3}\frac{r^3}{r_0^3} = \frac{4}{3}\frac{\left(1.1\times10^{-15}\text{m}\right)^3}{\left(0.529\times10^{-10}\text{m}/207\right)^3} = \boxed{1.1\times10^{-7}}$$

19. We follow the directions as given in the problem. We use the first integral listed in Appendix B-5.

$$\bar{r} = \int_0^\infty r\left|\psi_{100}\right|^2 4\pi r^2 dr = \int_0^\infty r\frac{1}{\pi r_0^3}e^{-2\frac{r}{r_0}}4\pi r^2 dr = 4\int_0^\infty \frac{r^3}{r_0^3}e^{-2\frac{r}{r_0}}dr \text{ ; let } x = 2\frac{r}{r_0} \rightarrow$$

$$\bar{r} = \tfrac{1}{4}r_0\int_0^\infty x^3 e^{-x}dx = \tfrac{1}{4}r_0(3!) = \boxed{\tfrac{3}{2}r_0}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

20. To show that ψ_{200} is normalized, we integrate $|\psi_{200}|^2$ over all space. Use substitution of variables and an integral from Appendix B-5.

$$\int_{\text{all space}} |\psi_{200}|^2\, dV = \int_0^\infty \frac{1}{32\pi r_0^3}\left(2-\frac{r}{r_0}\right)e^{-\frac{r}{r_0}} 4\pi r^2 dr\ ; \quad \text{let } x=\frac{r}{r_0} \ \rightarrow\ r=r_0 x\ ,\ dr=r_0 dx$$

Note that if $r=0, x=0$ and if $r=\infty, x=\infty$.

$$\int_{\text{all space}} |\psi_{200}|^2\, dV = \int_0^\infty \frac{1}{32\pi r_0^3}\left(2-\frac{r}{r_0}\right)^2 e^{-\frac{r}{r_0}} 4\pi r^2 dr = \frac{4\pi}{32\pi r_0^3}\int_0^\infty (2-x)^2 e^{-x} r_0^2 x^2 r_0 dx$$

$$= \frac{1}{8}\int_0^\infty (2-x)^2 e^{-x} x^2 dx = \frac{1}{8}\int_0^\infty \left(4x^2-4x^3+x^4\right)e^{-x}dx = \frac{1}{2}\int_0^\infty x^2 e^{-x}dx - \frac{1}{2}\int_0^\infty x^3 e^{-x}dx + \frac{1}{8}\int_0^\infty x^4 e^{-x}dx$$

$$= \frac{1}{2}(2!) - \frac{1}{2}(3!) + \frac{1}{8}(4!) = 1-3+3=1$$

And so we see that ψ_{200} is normalized.

21. We follow the directions as given in the problem. The three wave functions are given in Eq. 39-9. We explicitly show the expressions involving the complex conjugate.

$$P_r = 4\pi r^2\left[\tfrac{1}{3}|\psi_{210}|^2 + \tfrac{1}{3}|\psi_{211}|^2 + \tfrac{1}{3}|\psi_{21-1}|^2\right]$$

$$= 4\pi r^2\left[\tfrac{1}{3}\left(\frac{z^2}{32\pi r_0^5}e^{-\frac{r}{r_0}}\right) + \tfrac{1}{3}\left(\frac{(x+iy)(x-iy)}{64\pi r_0^5}e^{-\frac{r}{r_0}}\right) + \tfrac{1}{3}\left(\frac{(x+iy)(x-iy)}{64\pi r_0^5}e^{-\frac{r}{r_0}}\right)\right]$$

$$= 4\pi r^2\left[\tfrac{1}{3}\frac{z^2}{32\pi r_0^5}e^{-\frac{r}{r_0}} + \tfrac{1}{3}\frac{\left(x^2+y^2\right)}{64\pi r_0^5}e^{-\frac{r}{r_0}} + \tfrac{1}{3}\frac{\left(x^2+y^2\right)}{64\pi r_0^5}e^{-\frac{r}{r_0}}\right] = \frac{r^2}{24r_0^5}\left(z^2+x^2+y^2\right)e^{-\frac{r}{r_0}}$$

$$= \boxed{\frac{r^4}{24r_0^5}e^{-\frac{r}{r_0}}}$$

22. From Problem 21, we have that $P_r = \dfrac{r^4}{24r_0^5}e^{-\frac{r}{r_0}}$ for the 2*p* state. We find the most probable distance by setting $\dfrac{dP_r}{dr}=0$ and solving for *r*. This is very similar to Example 39-3.

$$P_r = \frac{r^4}{24r_0^5}e^{-\frac{r}{r_0}}\ ;\ \frac{dP_r}{dr} = \frac{4r^3}{24r_0^5}e^{-\frac{r}{r_0}} - \frac{1}{r_0}\frac{r^4}{24r_0^5}e^{-\frac{r}{r_0}} = (4r_0-r)\frac{r^3 e^{-\frac{r}{r_0}}}{r_0^6 24} = 0 \ \rightarrow\ \boxed{r=4r_0}$$

23. The probability is found by integrating the radial probability density over the range of radii given.

$$\text{P} = \int_{0.99r_0}^{1.01r_0} 4\frac{r^2}{r_0^3}e^{-\frac{2r}{r_0}}dr\ ;\ \text{let } x=2\frac{r}{r_0} \ \rightarrow$$

$$\text{P} = \tfrac{1}{2}\int_{1.98}^{2.02} x^2 e^{-x}dx = \tfrac{1}{2}\left[-e^{-x}\left(x^2+2x+2\right)\right]_{1.98}^{2.02} = e^{-1.98}(4.9402) - e^{-2.02}(5.0602) = 0.0108 \approx \boxed{1.1\%}$$

Because the range of radii is small and the radial probability density is relatively constant over that range (see Figure 39-7), we can approximate the probability as follows.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\mathrm{P}=\int_{0.99r_0}^{1.01r_0} 4\frac{r^2}{r_0^3}e^{-\frac{2r}{r_0}}dr \approx P\left(r=r_0\right)\Delta r = 4\frac{r_0^2}{r_0^3}e^{-\frac{2r_0}{r_0}}\left(0.02r_0\right)=0.08e^{-2}=0.0108\approx \boxed{1.1\%}$$

24. The probability is found by integrating the radial probability density over the range of radii given. The radial probability density is given after Eq. 39-8.

$$\mathrm{P}=\int_{4.00r_0}^{5.00r_0}\frac{r^2}{8r_0^3}\left(2-\frac{r}{r_0}\right)^2 e^{-\frac{r}{r_0}}dr \text{ ; let } x=\frac{r}{r_0} \quad \rightarrow$$

$$\mathrm{P}=\tfrac{1}{8}\int_{4.00}^{5.00} x^2\left(2-x\right)^2 e^{-x}dx=\tfrac{1}{8}\int_{4.00}^{5.00}\left(x^4-4x^3+4x^2\right)e^{-x}dx$$

There are some difficult integrals to evaluate. We use integration by parts.

$$\int x^2e^{-x}dx:\ \ u=x^2;\ dv=e^{-x};\ du=2xdx;\ v=-e^{-x}$$

$$\int x^2e^{-x}dx=-x^2e^{-x}+\int 2xe^{-x}dx=-x^2e^{-x}+2\left(-e^{-x}\right)\left(x+1\right)=-e^{-x}\left(x^2+2x+2\right)$$

$$\int x^3e^{-x}dx:\ \ u=x^3;\ dv=e^{-x};\ du=3x^2dx;\ v=-e^{-x}$$

$$\int x^3e^{-x}dx=-x^3e^{-x}+3\int x^2e^{-x}dx=-e^{-x}\left(x^3+3x^2+6x+6\right)$$

$$\int x^4e^{-x}dx:\ \ u=x^4;\ dv=e^{-x};\ du=4x^3dx;\ v=-e^{-x}$$

$$\int x^4e^{-x}dx=-x^4e^{-x}+4\int x^3e^{-x}dx=-e^{-x}\left(x^4+4x^3+12x^2+24x+24\right)$$

We substitute the integrals above into the expression for the probability. We are not showing the algebra.

$$\mathrm{P}=-\tfrac{1}{8}\left[e^{-x}\left(x^4+4x^2+8x+8\right)\right]_{4.00}^{5.00}=-\tfrac{1}{8}\left(773e^{-5}-360e^{-4}\right)=0.173=\boxed{17.3\%}$$

25. The wave function is given in Eq. 39-5a. Note that $r=\left(x^2+y^2+z^2\right)^{1/2}$. We will need the derivative relationship derived in the first line below.

$$\frac{\partial r}{\partial x}=\tfrac{1}{2}\left(x^2+y^2+z^2\right)2x=\frac{x}{r}\ \ ;\ \ \psi_{100}=\frac{1}{\sqrt{\pi r_0^3}}e^{-\frac{r}{r_0}}\ \ ;\ \ \frac{\partial\psi}{\partial x}=\frac{\partial\psi}{\partial r}\frac{\partial r}{\partial x}=-\frac{1}{r_0}\frac{1}{\sqrt{\pi r_0^3}}e^{-\frac{r}{r_0}}\frac{x}{r}$$

$$\frac{\partial^2\psi}{\partial x^2}=\frac{\partial}{\partial x}\left(-\frac{1}{r_0}\frac{1}{\sqrt{\pi r_0^3}}e^{-\frac{r}{r_0}}\frac{x}{r}\right)=\left(-\frac{1}{r_0}\frac{1}{\sqrt{\pi r_0^3}}e^{-\frac{r}{r_0}}\frac{1}{r}\right)+\frac{\partial}{\partial r}\left(-\frac{1}{r_0}\frac{1}{\sqrt{\pi r_0^3}}e^{-\frac{r}{r_0}}\frac{x}{r}\right)\frac{\partial r}{\partial x}$$

$$=\frac{-1}{rr_0}\frac{1}{\sqrt{\pi r_0^3}}e^{-\frac{r}{r_0}}\left[1-x^2\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right]=-\psi\frac{1}{rr_0}\left[1-x^2\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right]$$

Similarly, we would have $\frac{\partial r}{\partial y}=\frac{y}{r}$; $\frac{\partial^2\psi}{\partial y^2}=-\psi\frac{1}{rr_0}\left[1-y^2\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right]$; $\frac{\partial r}{\partial z}=\frac{z}{r}$; and

$\frac{\partial^2\psi}{\partial z^2}=-\psi\frac{1}{rr_0}\left[1-z^2\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right]$. Substitute into the time-independent Schrödinger equation.

$$E\psi=-\frac{\hbar^2}{2m}\left(\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial x^2}\right)-\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r}\psi$$

$$=\left(-\frac{\hbar^2}{2m}\right)\left(-\psi\frac{1}{rr_0}\right)\left\{\left[1-x^2\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right]+\left[1-y^2\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right]+\left[1-z^2\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right]\right\}-\frac{e^2}{4\pi\varepsilon_0 r}\psi$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \psi\left[\frac{\hbar^2}{2m}\frac{1}{rr_0}\left\{3-\left(x^2+y^2+z^2\right)\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right\}-\frac{e^2}{4\pi\varepsilon_0 r}\right]$$

$$= \psi\left[\frac{\hbar^2}{2m}\frac{1}{rr_0}\left\{3-r^2\left(\frac{1}{rr_0}+\frac{1}{r^2}\right)\right\}-\frac{e^2}{4\pi\varepsilon_0 r}\right] = \psi\left[\frac{\hbar^2}{2m}\frac{1}{rr_0}\left(2-\frac{r^2}{rr_0}\right)-\frac{e^2}{4\pi\varepsilon_0 r}\right]$$

$$= \psi\left[\frac{\hbar^2}{mrr_0}-\frac{\hbar^2}{2mr_0^2}-\frac{e^2}{4\pi\varepsilon_0 r}\right]$$

Since the factor in square brackets must be a constant, the terms with the *r* dependence must cancel.

$$\frac{\hbar^2}{mrr_0}-\frac{e^2}{4\pi\varepsilon_0 r}=0 \;\rightarrow\; r_0=\frac{4\pi\varepsilon_0\hbar^2}{me^2}=\frac{\varepsilon_0 h^2}{\pi me^2}$$

Note from Equation 37-11 that this expression for r_0 is the same as the Bohr radius. Since those two terms cancel, we are left with the following.

$$E\psi=-\frac{\hbar^2}{2mr_0^2}\psi \;\rightarrow\; E=-\frac{\hbar^2}{2mr_0^2}=-\frac{\hbar^2}{2m\left(\frac{\varepsilon_0 h^2}{\pi me^2}\right)^2}=\boxed{-\frac{me^4}{8h^2\varepsilon_0^2}}$$

26. (*a*) The probability is found by integrating the radial probability density over the range of radii given. The radial probability density is given after Eq. 39-8.

$$\mathrm{P}=\int_0^{r_0}\frac{r^2}{8r_0^3}\left(2-\frac{r}{r_0}\right)^2 e^{-\frac{r}{r_0}}dr \text{ ; let } x=\frac{r}{r_0} \;\rightarrow$$

$$\mathrm{P}=\tfrac{1}{8}\int_0^1 x^2\left(2-x\right)^2 e^{-x}dx=\tfrac{1}{8}\int_0^1\left(x^4-4x^3+4x^2\right)e^{-x}dx$$

The following integrals are derived in the solution to Problem 24.

$$\int x^2e^{-x}dx=-e^{-x}\left(x^2+2x+2\right) \;;\; \int x^3e^{-x}dx=-e^{-x}\left(x^3+3x^2+6x+6\right)$$

$$\int x^4e^{-x}dx=-e^{-x}\left(x^4+4x^3+12x^2+24x+24\right)$$

$$\mathrm{P}=\tfrac{1}{8}\int_0^1\left(x^4-4x^3+4x^2\right)e^{-x}dx$$

$$=\tfrac{1}{8}\left\{-e^{-x}\left[\left(x^4+4x^3+12x^2+24x+24\right)-4\left(x^3+3x^2+6x+6\right)+4\left(x^2+2x+2\right)\right]\right\}_0^1$$

$$=\tfrac{1}{8}\left[e^{-x}\left(x^4+4x^2+8x+8\right)\right]_1^0=\tfrac{1}{8}\left(8-21e^{-1}\right)=0.0343\approx\boxed{3.4\%}$$

(*b*) From Problem 21, we have that the radial probability density for this state is $P_{\mathrm{r}}=\frac{r^4}{24r_0^5}e^{-\frac{r}{r_0}}$. We proceed as in part (*a*).

$$\mathrm{P}=\int_0^{r_0}\frac{r^4}{24r_0^5}e^{-\frac{r}{r_0}}dr \text{ ; let } x=\frac{r}{r_0} \;\rightarrow$$

$$\mathrm{P}=\tfrac{1}{24}\int_0^1 x^4e^{-x}dx=\tfrac{1}{24}\left[-e^{-x}\left(x^4+4x^3+12x^2+24x+24\right)\right]_0^1=\tfrac{1}{24}\left(24-65e^{-1}\right)=3.66\times10^{-3}$$

$$\approx\boxed{0.37\%}$$

27. (*a*) The radial probability distribution is given by Eq. 39-6. Use the wave function given.

$$P_r = 4\pi r^2 |\psi_{300}|^2 = 4\pi r^2 \frac{1}{27\pi r_0^3}\left(1-\frac{2r}{3r_0}+\frac{2r^2}{27r_0^2}\right)^2 e^{-\frac{2r}{3r_0}} = \boxed{\frac{4r^2}{27r_0^3}\left(1-\frac{2r}{3r_0}+\frac{2r^2}{27r_0^2}\right)^2 e^{-\frac{2r}{3r_0}}}$$

(*b*) See the graph.

(*c*) The most probable distance is the radius for which the radial probability distribution has a global maximum. We find that location by setting $\frac{dP_r}{dr}=0$ and solving for *r*. We see from the graph that the global maximum is approximately at $r = 13r_0$.

$$\frac{dP_r}{dr} = \frac{8r}{27r_0^3}\left(1-\frac{2r}{3r_0}+\frac{2r^2}{27r_0^2}\right)^2 e^{-\frac{2r}{3r_0}} + \frac{8r^2}{27r_0^3}\left(1-\frac{2r}{3r_0}+\frac{2r^2}{27r_0^2}\right)\left(-\frac{2}{3r_0}+\frac{4r}{27r_0^2}\right)e^{-\frac{2r}{3r_0}}$$
$$+\frac{4r^2}{27r_0^3}\left(1-\frac{2r}{3r_0}+\frac{2r^2}{27r_0^2}\right)^2\left(-\frac{2}{3r_0}\right)e^{-\frac{2r}{3r_0}}$$
$$= \frac{8r}{27r_0^3}\left(1-\frac{2r}{3r_0}+\frac{2r^2}{27r_0^2}\right)\left(1-\frac{5r}{3r_0}+\frac{12r^2}{27r_0^2}-\frac{2r^3}{81r_0^3}\right)e^{-\frac{2r}{3r_0}} = 0$$

The above system has 6 non-infinite solutions. One solution is *r* = 0, which leads to $P_r = 0$, which is not a maximum for the radial distribution. The second-order polynomial, $\left(1-\frac{2r}{3r_0}+\frac{2r^2}{27r_0^2}\right)$, is a factor of the radial probability distribution, and so its zeros also give locations where $P_r = 0$. So the maxima must be found from the roots of the third-order polynomial. A spreadsheet was used to find the roots of $1-\frac{5}{3}x+\frac{12}{27}x^2-\frac{2}{81}x^3=0$. Those roots are $x = 0.74,\ 4.19$, and 13.07. So the most probable distance is $r = \boxed{13.1r_0}$.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH39.XLS," on tab "Problem 39.27."

28. For oxygen, *Z* = 8. We start with the $n=1$ shell, and list the quantum numbers in the order (n,ℓ,m_ℓ,m_s).

$$\boxed{\begin{array}{l}\left(1,0,0,-\tfrac{1}{2}\right),\left(1,0,0,+\tfrac{1}{2}\right),\left(2,0,0,-\tfrac{1}{2}\right),\left(2,0,0,+\tfrac{1}{2}\right),\\ \left(2,1,-1,-\tfrac{1}{2}\right),\left(2,1,-1,+\tfrac{1}{2}\right),\left(2,1,0,-\tfrac{1}{2}\right),\left(2,1,0,+\tfrac{1}{2}\right)\end{array}}$$

Note that, without additional information, there are two other possibilities that could substitute for any of the last four electrons.

29. (*a*) For carbon, *Z* = 6. We start with the $n=1$ shell, and list the quantum numbers in the order (n,ℓ,m_ℓ,m_s).

$$\boxed{\left(1,0,0,-\tfrac{1}{2}\right),\left(1,0,0,+\tfrac{1}{2}\right),\left(2,0,0,-\tfrac{1}{2}\right),\left(2,0,0,+\tfrac{1}{2}\right),\left(2,1,-1,-\tfrac{1}{2}\right),\left(2,1,-1,+\tfrac{1}{2}\right)}$$

Note that, without additional information, there are other possibilities for the last two electrons.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) For aluminum, $Z = 13$. We start with the $n = 1$ shell, and list the quantum numbers in the order (n, ℓ, m_ℓ, m_s).

$$\boxed{\begin{array}{l}\left(1,0,0,-\tfrac{1}{2}\right),\left(1,0,0,+\tfrac{1}{2}\right),\left(2,0,0,-\tfrac{1}{2}\right),\left(2,0,0,+\tfrac{1}{2}\right),\left(2,1,-1,-\tfrac{1}{2}\right),\left(2,1,-1,+\tfrac{1}{2}\right),\\ \left(2,1,0,-\tfrac{1}{2}\right),\left(2,1,0,+\tfrac{1}{2}\right),\left(2,1,1,-\tfrac{1}{2}\right),\left(2,1,1,+\tfrac{1}{2}\right),\left(3,0,0,-\tfrac{1}{2}\right),\left(3,0,0,+\tfrac{1}{2}\right),\left(3,1,-1,-\tfrac{1}{2}\right)\end{array}}$$

Note that, without additional information, there are other possibilities for the last electron.

30. The number of electrons in the subshell is determined by the value of ℓ. For each ℓ the value of m_ℓ can range from $-\ell$ to $+\ell$, which is $2\ell + 1$ values. For each m_ℓ value there are two values of m_s. Thus the total number of states for a given ℓ is $N = 2(2\ell + 1)$.

$$N = 2(2\ell + 1) = 2\left[2(4) + 1\right] = \boxed{18 \text{ electrons}}$$

31. Since the electron is in its lowest energy state, we must have the lowest possible value of *n*. Since $m_\ell = 2$, the smallest possible value of ℓ is $\boxed{\ell = 2}$, and the smallest possible value of *n* is $\boxed{n = 3}$.

32. Limiting the number of electron shells to six would mean that the periodic table stops with radon (Rn), since the next element, francium (Fr), begins filling the seventh shell. Including all elements up through radon means $\boxed{86}$ elements.

33. (*a*) Nickel has $Z = 28$.

$$\boxed{1s^2 2s^2 2p^6 3s^2 3p^6 3d^8 4s^2}$$

(*b*) Silver has $Z = 47$.

$$\boxed{1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 5s^1}$$

(*c*) Uranium has $Z = 92$.

$$\boxed{1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 4f^{14} 5s^2 5p^6 5d^{10} 6s^2 6p^6 5f^3 6d^1 7s^2}$$

34. The third electron in lithium is in the 2*s* subshell, which is outside the more tightly bound filled 1*s* shell. This makes it appear as if there is a "nucleus" with a net charge of +1e. Thus we use the energy of the hydrogen atom.

$$E_2 = -\frac{(13.6\,\text{eV})}{n^2} = -\frac{(13.6\,\text{eV})}{2^2} = -3.4\,\text{eV}$$

We predict the binding energy to be $\boxed{3.4\text{ eV}}$. Our assumption of complete shielding of the nucleus by the 2*s* electrons is probably not correct. The partial shielding means the net charge of the "nucleus" is higher than +1e, and so it holds the outer electron more tightly, requiring more energy to remove it.

35. We use Eq. 37-13, which says that the radius of a Bohr orbit is inversely proportional to the atomic number. We also use Eq. 37-14b, which says that the energy of Bohr orbit is proportional to the square of the atomic number. The energy to remove the electron is the opposite of the total energy.

$$r_n = \frac{n^2}{Z}\left(0.529\times10^{-10}\,\text{m}\right) = \frac{1}{92}\left(0.529\times10^{-10}\,\text{m}\right) = \boxed{5.75\times10^{-13}\,\text{m}}$$

$$|E_n| = (13.6\,\text{eV})\frac{Z^2}{n^2} = (13.6\,\text{eV})\frac{92^2}{1^2} = \boxed{1.15\times10^5\,\text{eV}}$$

36. The energy levels of the infinite square well are given in Eq. 38-13. Each energy level can have a maximum of two electrons, since the only quantum numbers are n and m_s. Thus the lowest energy level will have two electrons in the $n = 1$ state, two electrons in the $n = 2$ state, and 1 electron in the $n = 3$ state.

$$E = 2E_1 + 2E_2 + E_3 = \left[2(1)^2 + 2(2^2) + 1(3)^2\right]\frac{h^2}{8m\ell^2} = \boxed{19\frac{h^2}{8m\ell^2}}$$

37. In a filled subshell, there are an even number of electrons. All of the possible quantum number combinations for electrons in that subshell represent an electron that is present. Thus for every m_ℓ value, both values of m_s are filled, representing a spin "up" state and a spin "down" state. The total angular momentum of that pair is zero, and since all of the electrons are paired, the total angular momentum is zero.

38. The shortest wavelength X-ray has the most energy, which is the maximum kinetic energy of the electron in the tube:

$$E = \frac{hc}{\lambda} = \frac{(6.63\times10^{-34}\ \text{J•s})(3.00\times10^{8}\ \text{m/s})}{(1.60\times10^{-19}\ \text{J/eV})(0.027\times10^{-9}\ \text{m})} = 4.6\times10^{4}\ \text{eV} = 46\,\text{keV}$$

Thus the operating voltage of the tube is $\boxed{46\,\text{kV}}$.

39. The shortest wavelength X-ray has the most energy, which is the maximum kinetic energy of the electron in the tube.

$$\lambda = \frac{hc}{E} = \frac{(6.63\times10^{-34}\ \text{J•s})(3.00\times10^{8}\ \text{m/s})}{(1.60\times10^{-19}\ \text{J/eV})(32.5\times10^{3}\ \text{eV})} = 3.825\times10^{-11}\,\text{m} = \boxed{0.0383\,\text{nm}}$$

The longest wavelength of the continuous spectrum would be at the limit of the X-ray region of the electromagnetic spectrum, generally on the order of 1 nm.

40. The energy of the photon with the shortest wavelength must equal the maximum kinetic energy of an electron. We assume V is in volts.

$$E = hf_0 = \frac{hc}{\lambda_0} = eV \quad \rightarrow$$

$$\lambda_0 = \frac{hc}{eV} = \frac{(6.63\times10^{-34}\ \text{J•s})(3.00\times10^{8}\ \text{m/s})(10^{9}\ \text{nm/m})}{(1.60\times10^{-19}\,\text{C})(V\,\text{V})} = \frac{1243\,\text{nm}}{V} \approx \boxed{\frac{1240\,\text{nm}}{V}}$$

41. With the shielding provided by the remaining $n = 1$ electron, we use the energies of the hydrogen atom with Z replaced by $Z - 1$. The energy of the photon is found, and then the wavelength.

$$hf = \Delta E = -(13.6\,\text{eV})(26-1)^2\left[\left(\frac{1}{2^2}\right) - \left(\frac{1}{1^2}\right)\right] = 6.40\times10^{3}\,\text{eV}.$$

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.63\times10^{-34}\ \text{J•s})(3.00\times10^{8}\ \text{m/s})}{(1.60\times10^{-19}\ \text{J/eV})(6.40\times10^{3}\ \text{eV})} = 1.94\times10^{-10}\,\text{m} = \boxed{0.194\,\text{nm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

42. We follow the procedure of Example 39-6, of using the Bohr formula, Eq. 37-15, with Z replaced by $Z-1$.

$$\frac{1}{\lambda}=\left(\frac{e^4m}{8\varepsilon_0^2h^3c}\right)(Z-1)^2\left(\frac{1}{n'^2}-\frac{1}{n^2}\right)=\left(1.097\times10^7\,\text{m}^{-1}\right)(27-1)^2\left(\frac{1}{1^2}-\frac{1}{2^2}\right)=5.562\times10^9\,\text{m}^{-1}\quad\rightarrow$$

$$\lambda=\frac{1}{5.562\times10^9\,\text{m}^{-1}}=\boxed{1.798\times10^{-10}\,\text{m}}$$

43. The wavelength of the K_α line is calculated for molybdenum in Example 39-6. We use that same procedure. Note that the wavelength is inversely proportional to $(Z-1)^2$.

$$\frac{\lambda_{\text{unknown}}}{\lambda_{\text{Fe}}}=\frac{(Z_{\text{Fe}}-1)^2}{(Z_{\text{unknown}}-1)^2}\quad\rightarrow\quad Z_{\text{unknown}}=\left[(26-1)\sqrt{\frac{194\,\text{pm}}{229\,\text{pm}}}\right]+1=24$$

The unknown material has $Z = 24$, and so is chromium.

44. We assume that there is "shielding" provided by the 1*s* electron that is already at that level. Thus the effective charge "seen" by the transitioning electron is 42 – 1 = 41. We use Eqs. 37-9 and 37-14b.

$$hf=\Delta E=(13.6\,\text{eV})(Z-1)^2\left(\frac{1}{n'^2}-\frac{1}{n^2}\right)$$

$$\lambda=\frac{hc}{\Delta E}=\frac{hc}{(13.6\,\text{eV})(Z-1)^2\left(\frac{1}{n'^2}-\frac{1}{n^2}\right)}=\frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^8\,\text{m/s}\right)}{(13.6\,\text{eV})\left(41^2\right)\left(\frac{1}{1^2}-\frac{1}{3^2}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}$$

$$=6.12\times10^{-11}\,\text{m}=\boxed{0.0612\,\text{nm}}$$

We do not expect perfect agreement because there is some partial shielding provided by the $n = 2$ shell, which was ignored when we replaced Z by $Z - 1$. That would make the effective atomic number a little smaller, which would lead to a larger wavelength. The amount of shielding could be estimated by using the actual wavelength and solving for the effective atomic number.

45. Momentum and energy will be conserved in any inertial reference frame. Consider the frame of reference that is moving with the same velocity as the electron's initial velocity. In that frame of reference, the initial momentum of the electron is 0, and its initial total energy is mc^2. Let the emitted photon have frequency f, and let the direction of motion of that photon be considered the positive direction. The momentum of the photon is then $p_\gamma=\frac{h}{\lambda}=\frac{hf}{c}$, and so the momentum of the electron must be $p_e=-\frac{hf}{c}$. The final energy of the photon is $E_\gamma=hf=p_\gamma c$, and the final energy of the electron is, from Eq. 36-13, $E_{\substack{\text{electron}\\\text{final}}}=\sqrt{p_e^2c^2+m^2c^4}$. We write the conservation conditions, and then solve for the frequency of the emitted photon.

Momentum: $0=\frac{hf}{c}+p_e\quad\rightarrow\quad p_e=-\frac{hf}{c}$

Energy: $mc^2=hf+\sqrt{p_e^2c^2+m^2c^4}$

$$mc^2-hf=\sqrt{\left(\frac{hf}{c}\right)^2c^2+m^2c^2}=\sqrt{h^2f^2+m^2c^4}$$

$$m^2c^4-2mc^2hf+h^2f^2=h^2f^2+m^2c^4\quad\rightarrow\quad 2mc^2hf=0\quad\rightarrow\quad f=0$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Since the photon must have $f = 0$, no photon can be emitted and still satisfy the conservation laws.

Another way to consider this situation is that if an electron at rest emits a photon, the energy of the electron must decrease for energy to be conserved. But the energy of a stationary electron cannot decrease, unless its mass were to change. Then it would no longer be an electron.

So we conclude that a third object (with mass) must be present in order for both energy and momentum to be conserved.

46. The Bohr magneton is given by Eq. 39-12.

$$\mu_B = \frac{e\hbar}{2m} = \frac{\left(1.602\times10^{-19}\,\text{C}\right)\left(1.054\times10^{-34}\,\text{J•s}\right)}{2\left(9.109\times10^{-31}\,\text{kg}\right)} = \boxed{9.27\times10^{-24}\,\text{J/T}}$$

47. We use Eq. 39-14 for the magnetic moment, since the question concerns spin angular momentum. The energy difference is the difference in the potential energies of the two spin states.

$$\Delta U = \left(\mu_z B\right)_{\text{spin up}}^{\text{spin down}} = -g\mu_B B\Delta m_s = -\left(2.0023\right)\frac{\left(9.27\times10^{-24}\,\text{J/T}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)}\left(2.5\text{T}\right)\left(-\tfrac{1}{2}-\tfrac{1}{2}\right) = \boxed{2.9\times10^{-4}\,\text{eV}}$$

48. (*a*) The energy difference is the difference in the potential energies of the two spin states. Use Eq. 39-14 for the magnetic moment.

$$\Delta U = \left(\mu_z B\right)_{\text{spin up}}^{\text{spin down}} = -g\mu_B B\Delta m_s = -\left(2.0023\right)\frac{\left(9.27\times10^{-24}\,\text{J/T}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)}\left(1.0\,\text{T}\right)\left(-\tfrac{1}{2}-\tfrac{1}{2}\right)$$

$$= 1.160\times10^{-4}\,\text{eV} \approx \boxed{1.2\times10^{-4}\,\text{eV}}$$

(*b*) Calculate the wavelength associated with this energy change.

$$\Delta U = E = h\frac{c}{\lambda} \quad \rightarrow$$

$$\lambda = \frac{hc}{\Delta U} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.160\times10^{-4}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 1.072\times10^{-2}\,\text{m} \approx \boxed{1.1\text{cm}}$$

(*c*) The answer would be no different for hydrogen. The splitting for both atoms is due to an *s*-state electron: 1*s* for hydrogen, 5*s* for silver. See the discussion on page 1058 concerning the Stern-Gerlach experiment.

49. (*a*) Refer to Figure 39-14 and the equation following it. A constant magnetic field gradient will produce a constant force on the silver atoms. Atoms with the valence electron in one of the spin states will experience an upward force, and atoms with the valence electron in the opposite spin state will experience a downward force. That constant force will produce a constant acceleration, leading to the deflection from the original direction of the atoms as they leave the oven. We assume the initial direction of the atoms is the *x* direction, and the magnetic field gradient is in the *z* direction. If undeflected, that atoms would hit the screen at $z = 0$.

$$z = \tfrac{1}{2}at^2 = \tfrac{1}{2}\frac{F}{m_{\text{Ag}}}\left(\frac{\Delta x}{v}\right)^2 = \tfrac{1}{2}\frac{\mu_z\dfrac{dB_z}{dz}}{m_{\text{Ag}}}\left(\frac{\Delta x}{v}\right)^2 = \tfrac{1}{2}\frac{\left(-g\mu_B m_s\right)\dfrac{dB_z}{dz}}{m_{\text{Ag}}}\left(\frac{\Delta x}{v}\right)^2$$

One beam is deflected up, and the other down. There separation is the difference in the two deflections due to the two spin states.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\Delta z = z_{m_s=-\frac{1}{2}} - z_{m_s=\frac{1}{2}} = \tfrac{1}{2}\frac{\left[-g\mu_B\left(-\frac{1}{2}-\frac{1}{2}\right)\right]\frac{dB_z}{dz}}{m_{\text{Ag}}}\left(\frac{\Delta x}{v}\right)^2$$

$$= \tfrac{1}{2}\frac{(2.0023)\left(9.27\times10^{-24}\,\text{J/T}\right)(1800\,\text{T/m})}{(107.87\,\text{u})\left(1.66\times10^{-27}\,\text{kg/u}\right)}\left(\frac{0.050\,\text{m}}{780\,\text{m/s}}\right)^2 = 3.833\times10^{-4}\,\text{m} \approx \boxed{0.38\,\text{mm}}$$

(*b*) The separation is seen in the above equation to be proportional to the *g*-factor. So to find the new deflection, divide the answer to part (a) by the original *g*-factor.

$$\Delta z_{g=1} = \frac{3.833\times10^{-4}\,\text{m}}{2.0023} \approx \boxed{0.19\,\text{mm}}$$

50. For the 5*g* state, $\ell = 4$ and $s = \frac{1}{2}$. Thus the possible values of *j* are $j = \ell \pm s = 4 \pm \frac{1}{2} = \boxed{\frac{7}{2}, \frac{9}{2}}$.

Let $j = \frac{7}{2}$. Then we have the following.

$$\boxed{\begin{aligned} &m_j = -\tfrac{7}{2}, -\tfrac{5}{2}, -\tfrac{3}{2}, -\tfrac{1}{2}, \tfrac{1}{2}, \tfrac{3}{2}, \tfrac{5}{2}, \tfrac{7}{2} \qquad J = \sqrt{\tfrac{7}{2}\left(\tfrac{7}{2}+1\right)}\hbar = \frac{3\sqrt{7}}{2}\hbar \\ &J_z = m_j\hbar = -\tfrac{7}{2}\hbar, -\tfrac{5}{2}\hbar, -\tfrac{3}{2}\hbar, -\tfrac{1}{2}\hbar, \tfrac{1}{2}\hbar, \tfrac{3}{2}\hbar, \tfrac{5}{2}\hbar, \tfrac{7}{2}\hbar \end{aligned}}$$

Let $j = \frac{9}{2}$. Then we have the following.

$$\boxed{\begin{aligned} &m_j = -\tfrac{9}{2}, -\tfrac{7}{2}, -\tfrac{5}{2}, -\tfrac{3}{2}, -\tfrac{1}{2}, \tfrac{1}{2}, \tfrac{3}{2}, \tfrac{5}{2}, \tfrac{7}{2}, \tfrac{9}{2} \qquad J = \sqrt{\tfrac{9}{2}\left(\tfrac{9}{2}+1\right)}\hbar = \frac{3\sqrt{11}}{2}\hbar \\ &J_z = m_j\hbar = -\tfrac{9}{2}\hbar, -\tfrac{7}{2}\hbar, -\tfrac{5}{2}\hbar, -\tfrac{3}{2}\hbar, -\tfrac{1}{2}\hbar, \tfrac{1}{2}\hbar, \tfrac{3}{2}\hbar, \tfrac{5}{2}\hbar, \tfrac{7}{2}\hbar, \tfrac{9}{2}\hbar \end{aligned}}$$

51. (*a*) For the 4*p* state, $\ell = 1$. Since $s = \frac{1}{2}$, the possible values for *j* are $j = \ell + s = \boxed{\frac{3}{2}}$ and $j = \ell - s = \boxed{\frac{1}{2}}$.

(*b*) For the 4*f* state, $\ell = 3$. Since $s = \frac{1}{2}$, the possible values for *j* are $j = \ell + s = \boxed{\frac{7}{2}}$ and $j = \ell - s = \boxed{\frac{5}{2}}$.

(*c*) For the 3*d* state, $\ell = 2$. Since $s = \frac{1}{2}$, the possible values for *j* are $j = \ell + s = \boxed{\frac{5}{2}}$ and $j = \ell - s = \boxed{\frac{3}{2}}$.

(*d*) The values of *J* are found from Eq. 39-15.

$$4p: \quad J = \sqrt{j(j+1)}\hbar = \boxed{\frac{\sqrt{15}}{2}\hbar \text{ and } \frac{\sqrt{3}}{2}\hbar}$$

$$4f: \quad J = \sqrt{j(j+1)}\hbar = \boxed{\frac{\sqrt{63}}{2}\hbar \text{ and } \frac{\sqrt{35}}{2}\hbar}$$

$$3d: \quad J = \sqrt{j(j+1)}\hbar = \boxed{\frac{\sqrt{35}}{2}\hbar \text{ and } \frac{\sqrt{15}}{2}\hbar}$$

52. (*a*) Gallium has *Z* = 31. We list the quantum numbers in the order (n, ℓ, m_ℓ, m_s).

$$\boxed{\begin{aligned} &\left(1,0,0,-\tfrac{1}{2}\right),\left(1,0,0,+\tfrac{1}{2}\right),\left(2,0,0,-\tfrac{1}{2}\right),\left(2,0,0,+\tfrac{1}{2}\right),\left(2,1,-1,-\tfrac{1}{2}\right),\left(2,1,-1,+\tfrac{1}{2}\right), \\ &\left(2,1,0,-\tfrac{1}{2}\right),\left(2,1,0,+\tfrac{1}{2}\right),\left(2,1,1,-\tfrac{1}{2}\right),\left(2,1,1,+\tfrac{1}{2}\right),\left(3,0,0,-\tfrac{1}{2}\right),\left(3,0,0,+\tfrac{1}{2}\right), \end{aligned}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\boxed{\begin{array}{l}\left(3,1,-1,-\tfrac{1}{2}\right),\left(3,1,-1,+\tfrac{1}{2}\right),\left(3,1,0,-\tfrac{1}{2}\right),\left(3,1,0,+\tfrac{1}{2}\right),\left(3,1,1,-\tfrac{1}{2}\right),\left(3,1,1,+\tfrac{1}{2}\right),\\ \left(3,2,-2,-\tfrac{1}{2}\right),\left(3,2,-2,+\tfrac{1}{2}\right),\left(3,2,-1,-\tfrac{1}{2}\right),\left(3,2,-1,+\tfrac{1}{2}\right),\left(3,2,0,-\tfrac{1}{2}\right),\left(3,2,0,+\tfrac{1}{2}\right),\\ \left(3,2,1,-\tfrac{1}{2}\right),\left(3,2,1,+\tfrac{1}{2}\right),\left(3,2,2,-\tfrac{1}{2}\right),\left(3,2,-2,+\tfrac{1}{2}\right),\left(4,0,0,-\tfrac{1}{2}\right),\left(4,0,0,+\tfrac{1}{2}\right),\\ \left(4,1,0,+\tfrac{1}{2}\right)\end{array}}$$

The last electron listed could have other quantum numbers for m_ℓ and m_s.

(*b*) The $\boxed{1s,\ 2s,\ 2p,\ 3s,\ 3p,\ 3d,\text{ and }4s}$ subshells are filled.

(*c*) For a 4*p* state, $\ell = 1$. Since $s = \frac{1}{2}$, the possible values for *j* are $j = \ell + s = \boxed{\frac{3}{2}}$ and $j = \ell - s = \boxed{\frac{1}{2}}$.

(*d*) The 4*p* electron is the only electron not in a filled subshell. The angular momentum of a filled subshell is zero, so the total angular momentum of the atom is the angular momentum of the 4*p* electron.

(*e*) When the beam passes through the magnetic field gradient, the deflecting force will be proportional to m_j. If $j = \frac{1}{2}$, the values of m_j are $\pm\frac{1}{2}$, and there will be two lines. If $j = \frac{3}{2}$, the values of m_j are $\pm\frac{1}{2}, \pm\frac{3}{2}$, and there will be four lines. $\boxed{\text{The number of lines indicates the value of } j.}$

53. (*a*) The additional term for the spin-orbit interaction is given in the text as $U_{\substack{\text{spin}\\\text{orbit}}} = -\vec{\boldsymbol{\mu}}\cdot\vec{\mathbf{B}}_{\text{n}} = \mu_z B_{\text{n}}$.

The separation of the energy levels due to the two different electron spins is twice this.

$$\Delta U_{\substack{\text{spin}\\\text{orbit}}} = \left(\mu_z B_{\text{n}}\right)_{\text{spin up}}^{\text{spin down}} = -g\mu_{\text{B}} B_{\text{n}} \Delta m_s \quad \rightarrow$$

$$B_{\text{n}} = \frac{\Delta U_{\substack{\text{spin}\\\text{orbit}}}}{-g\mu_{\text{B}}\Delta m_s} = \frac{\left(5\times10^{-5}\text{eV}\right)\left(1.60\times10^{-19}\text{ J/eV}\right)}{\left(2.0023\right)\left(9.27\times10^{-24}\text{ J/T}\right)\left(-\frac{1}{2}-\frac{1}{2}\right)} = 0.431\text{T} \approx \boxed{0.4\text{T}}$$

(*b*) If we consider the nucleus to be a loop of current with radius *r*, then the magnetic field due to the nucleus at the center of the loop (the location of the electron) is given in Example 28-12 as $B_{\text{n}} = \dfrac{\mu_0 I}{2r}$. Model the current as the charge of the nucleus moving in a circle, with a period as given by circular motion.

$$I = \frac{\Delta q}{\Delta t} = \frac{e}{T} = \frac{e}{2\pi r/v} = \frac{ev}{2\pi r} = \frac{e\left(m_e r\right)v}{2\pi r\left(m_e r\right)}$$

Note that classically, $m_e r v = L_e$, the angular momentum of the electron, and so $m_e r v = \sqrt{\ell(\ell+1)}\hbar$ with $\ell = 2$. Thus we have the following:

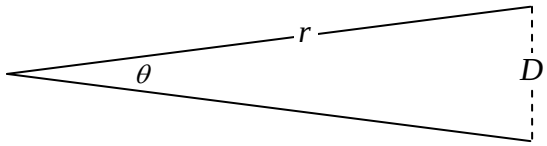
$$B_{\text{n}} = \frac{\mu_0 I}{2r} = \frac{\mu_0}{2r}\frac{e\sqrt{\ell(\ell+1)}\hbar}{2\pi m_e r^2} = \frac{e\hbar}{2m_e}\frac{\mu_0\sqrt{\ell(\ell+1)}}{2\pi r^3} = \frac{\mu_{\text{B}}\mu_0\sqrt{\ell(\ell+1)}}{2\pi r^3}$$

From Figure 39-9 (b), we see that the most probable radius for the $n = 2$, $\ell = 1$ state is approximately $r = 4r_0$. We can now calculate the approximate magnetic field.

$$B_{\text{n}} = \frac{\mu_{\text{B}}\mu_0\sqrt{\ell(\ell+1)}}{2\pi\left(4r_0\right)^3} = \frac{\left(9.27\times10^{-24}\text{ J/T}\right)\left(4\pi\times10^{-7}\text{ T}\cdot\text{m/A}\right)\sqrt{6}}{2\pi\left[4\left(0.529\times10^{-10}\text{ m}\right)\right]^3} = 0.479\text{T} \approx \boxed{0.5\text{T}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The two values are about $\dfrac{0.479\text{T} - 0.431\text{T}}{\frac{1}{2}(0.479\text{T} + 0.431\text{T})} \times 100 \approx 11\%$ different, and so are consistent.



54. The energy of a pulse is the power of the pulse times the duration in time.

$$E = P\,\Delta t = (0.63\text{W})\left(23 \times 10^{-3}\text{s}\right) = 0.01449\text{J} \approx \boxed{0.014\text{J}}$$

The number of photons in a pulse is the energy of a pulse, divided by the energy of a photon as given in Eq. 37-3.

$$N = \frac{E}{hf} = \frac{E\lambda}{hc} = \frac{(0.01449\text{J})\left(640 \times 10^{-9}\text{m}\right)}{\left(6.63 \times 10^{-34}\text{ J•s}\right)\left(3.00 \times 10^{8}\text{ m/s}\right)} = \boxed{4.7 \times 10^{16}\text{ photons}}$$

55. The angular half-width of the beam can be found in Section 35-4, and is given by $\theta_{1/2} = \dfrac{1.22\lambda}{d}$, where d is the diameter of the diffracting circle. The angular width of the beam is twice this. The linear diameter of the beam is then the angular width times the distance from the source of the light to the observation point, $D = r\theta$. See the diagram.

(*a*) $D = r\theta = r\dfrac{2.44\lambda}{d} = \left(380 \times 10^{3}\text{m}\right)\dfrac{2.44\left(694 \times 10^{-9}\text{m}\right)}{3.6 \times 10^{-3}\text{m}} = \boxed{180\text{m}}$

(*b*) $D = r\theta = r\dfrac{2.44\lambda}{d} = \left(384 \times 10^{6}\text{m}\right)\dfrac{2.44\left(694 \times 10^{-9}\text{m}\right)}{3.6 \times 10^{-3}\text{m}} = \boxed{1.8 \times 10^{5}\text{m}}$

56. Intensity equals power per unit area. The area of the light from the laser is assumed to be in a circular area, while the area intercepted by the light from a light bulb is the surface area of a sphere.

(*a*) $I = \dfrac{P}{S} = \dfrac{P}{\pi r^2} = \dfrac{0.50 \times 10^{-3}\text{W}}{\pi\left(1.5 \times 10^{-3}\text{m}\right)^2} = 70.74\text{W/m}^2 \approx \boxed{71\text{W/m}^2}$

(*b*) $I = \dfrac{P}{S} = \dfrac{P}{4\pi r^2} = \dfrac{15\text{W}}{4\pi\left(2.0\text{m}\right)^2} = 0.2984\text{W/m}^2 \approx 0.30\text{W/m}^2$

The laser beam is more intense by a factor of $\dfrac{70.74\text{W/m}^2}{0.2984\text{W/m}^2} = 237 \approx \boxed{240}$.

57. Transition from the E_3' state to the E_2' state releases photons with energy 1.96 eV, as shown in Figure 39-21. The wavelength is determined from the energy.

$$\lambda = \frac{hc}{\Delta E} = \frac{\left(6.63 \times 10^{-34}\text{ J•s}\right)\left(3.00 \times 10^{8}\text{ m/s}\right)}{\left(1.60 \times 10^{-19}\text{ J/eV}\right)\left(1.96\text{eV}\right)} = 6.34 \times 10^{-7}\text{m} = \boxed{634\text{nm}}$$

58. We use Eq. 39-16b.

$$\frac{N_2}{N_0} = e^{-\left(\frac{E_2 - E_0}{kT}\right)} = e^{-\left[\frac{(2.2\text{eV})(1.60\times10^{-19}\text{J/eV})}{(1.38\times10^{-23}\text{J/K})(300\text{K})}\right]} = e^{-85.0} = \boxed{1.2 \times 10^{-37}}$$

$$\frac{N_1}{N_0} = e^{-\left(\frac{E_2 - E_0}{kT}\right)} = e^{-\left[\frac{(1.8\text{eV})(1.60\times10^{-19}\text{J/eV})}{(1.38\times10^{-23}\text{J/K})(300\text{K})}\right]} = e^{-69.6} = \boxed{6.1 \times 10^{-31}}$$

59. The relative numbers of atoms in two energy states at a given temperature is given by Eq. 39-16b. From Figure 39-20, the energy difference between the two states is 2.2 eV.

$$\frac{N_2}{N_0} = e^{-\left(\frac{E_2 - E_0}{kT}\right)} \quad \rightarrow \quad T = -\left(\frac{E_2 - E_0}{k \ln \frac{N_2}{N_0}}\right) = -\left[\frac{(2.2\,\text{eV})(1.60\times10^{-19}\,\text{J/eV})}{(1.38\times10^{-23}\,\text{J/K})\ln 0.5}\right] = \boxed{3.7\times10^4\,\text{K}}$$

60. Consider Eq. 39-16b, with $E_n > E_{n'}$. To have a population inversion means that $N_n > N_{n'}$.

$$\frac{N_n}{N_{n'}} = e^{-\left(\frac{E_n - E_{n'}}{kT}\right)} > 1 \quad \rightarrow \quad \ln\frac{N_n}{N_{n'}} = -\left(\frac{E_n - E_{n'}}{kT}\right) > 0 \quad \rightarrow \quad \frac{E_n - E_{n'}}{kT} < 0$$

Since $E_n > E_{n'}$, to satisfy the last condition we must have $T < 0$, a negative temperature.

This negative "temperature" is not a contradiction. The Boltzmann distribution assumes that a system is in thermal equilibrium, and the inverted system is not in thermal equilibrium. The inversion cannot be maintained without adding energy to the system. If left to itself, the excited states will decay and the inversion will not be maintained.

61. (*a*) Boron has $Z = 4$, so the outermost electron has $n = 2$. We use the Bohr result with an effective *Z*. We might naively expect to get $Z_{\text{eff}} = 1$, indicating that the other three electrons shield the outer electron from the nucleus, or $Z_{\text{eff}} = 2$, indicating that only the inner two electrons accomplish the shielding.

$$E_2 = -\frac{(13.6\,\text{eV})(Z_{\text{eff}})^2}{n^2} \quad \rightarrow \quad -8.26\,\text{eV} = -\frac{(13.6\,\text{eV})(Z_{\text{eff}})^2}{2^2} \quad \rightarrow \quad Z_{\text{eff}} = \boxed{1.56}$$

This indicates that the second electron in the $n = 2$ shell does partially shield the electron that is to be removed.

(*b*) We find the average radius from the expression below.

$$r = \frac{n^2 r_1}{Z_{\text{eff}}} = \frac{2^2\left(0.529\times10^{-10}\,\text{m}\right)}{(1.56)} = \boxed{1.36\times10^{-10}\,\text{m}}$$

62. An *h* subshell has $\ell = 5$. For a given ℓ value, m_ℓ ranges from $-\ell$ to $+\ell$, taking on $2\ell + 1$ different values. For each m_ℓ there are 2 values of m_s. Thus the number of states for a given ℓ value is $2(2\ell + 1)$. Thus there are $2(2\ell + 1) = 2(11) = \boxed{22}$ possible electron states.

63. (*a*) Z = 25 is manganese.

$$\boxed{1s^2 2s^2 2p^6 3s^2 3p^6 3d^5 4s^2}$$

(*b*) Z = 34 is selenium.

$$\boxed{1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^4}$$

(*c*) Z = 39 is yttrium.

$$\boxed{1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^1 5s^2}$$

64. The value of ℓ can range from 0 to $n-1$. Thus for $n=6$, we have $0 \le \ell \le 5$. The magnitude of $\vec{\mathbf{L}}$ is given by Eq. 39-3, $L = \sqrt{\ell(\ell+1)}\hbar$.

$$\boxed{L_{\min} = 0 \ ; \ L_{\max} = \sqrt{30}\hbar}$$

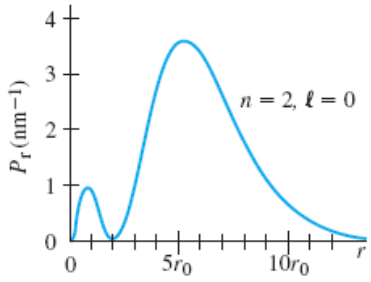
65. (*a*) We treat the Earth as a particle in rotation about the Sun. The angular momentum of a particle is given in Example 11-7 as $L = mvr$, where *r* is the orbit radius. We equate this to the quantum mechanical expression in Eq. 39-3. We anticipate that the quantum number will be very large, and so approximate $\left[\ell(\ell+1)\right]^{\frac{1}{2}}$ as ℓ.

$$L = M_{\text{Earth}} v r_{\substack{\text{Sun}- \\ \text{Earth}}} = \frac{M 2\pi r^2}{T} = \hbar\left[\ell(\ell+1)\right]^{\frac{1}{2}} = \hbar\ell \ \rightarrow$$

$$\ell = \frac{M_{\text{Earth}} 2\pi r^2}{\hbar T} = \frac{\left(5.98\times10^{24}\,\text{kg}\right)2\pi\left(1.496\times10^{11}\,\text{m}\right)^2}{\left(1.055\times10^{-34}\,\text{J•s}\right)\left(3.156\times10^{7}\,\text{s}\right)} = 2.5255\times10^{74} \approx \boxed{2.5\times10^{74}}$$

(*b*) There are $2\ell+1$ values of m_ℓ for a value of ℓ, so the number of orientations is as follows.

$$N = 2\ell + 1 = 2\left(2.5255\times10^{74}\right) + 1 = 5.051\times10^{74} \approx \boxed{5.1\times10^{74}}.$$



66. Eq. 37-15 gives the Bohr-theory result for the wavelength of a spectral line. For the Mosley plot, the wavelengths are for the K_α line, which has $n=2$ and $n'=1$. We assume that the shielding of the other *n* = 1 electron present reduces the effective atomic number to $Z-1$. We use the value of the Rydberg constant from Section 37-11.

$$\frac{1}{\lambda} = \left(\frac{Z^2e^4m}{8\varepsilon_0^2h^3c}\right)\left(\frac{1}{n'^2} - \frac{1}{n^2}\right) \ \rightarrow \ \frac{1}{\lambda} = \left(\frac{e^4m}{8\varepsilon_0^2h^3c}\right)Z^2\left(\frac{1}{1} - \frac{1}{4}\right) \ \rightarrow \ \frac{1}{\lambda} = \left(\frac{3e^4m}{32\varepsilon_0^2h^3c}\right)Z^2 \ \rightarrow$$

$$\frac{1}{\lambda} = \left(\frac{3e^4m}{32\varepsilon_0^2h^3c}\right)(Z-1)^2 \ \rightarrow \ \boxed{\sqrt{\frac{1}{\lambda}} = a(Z-b)}, \ a = \left(\frac{3e^4m}{32\varepsilon_0^2h^3c}\right)^{1/2}, \ b = 1$$

$$a = \left(\frac{3e^4m}{32\varepsilon_0^2h^3c}\right)^{1/2} = \left(\tfrac{3}{4}R\right)^{1/2} = \left[\tfrac{3}{4}\left(1.0974\times10^{7}\,\text{m}^{-1}\right)\right]^{1/2} = \boxed{2868.9\,\text{m}^{-1/2}}$$

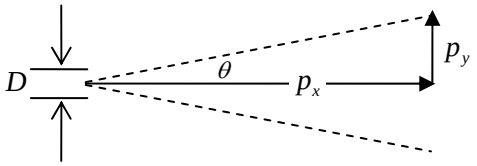
67. This is very similar to Example 39-3. We find the radial probability distribution for the *n* = 2, ℓ = 0 wave function, and find the position at which that distribution has a maximum. We see from Figure 39-8 that there will be two local maxima in the probability distribution function, and the global maximum is at approximately $5r_0$. The wave function is given in Eq. 39-8.

$$\psi_{200} = \frac{1}{\sqrt{32\pi r_0^3}}\left(2 - \frac{r}{r_0}\right)e^{-\frac{r}{2r_0}}$$

$$P_r = 4\pi r^2\left|\psi_{200}\right|^2 = \frac{r^2}{8r_0^3}\left(2 - \frac{r}{r_0}\right)^2 e^{-\frac{r}{r_0}}$$

$$\frac{dP_r}{dr} = \frac{2r}{8r_0^3}\left(2 - \frac{r}{r_0}\right)^2 e^{-\frac{r}{r_0}} + \frac{r^2}{8r_0^3}2\left(2 - \frac{r}{r_0}\right)\left(-\frac{1}{r_0}\right)e^{-\frac{r}{r_0}} + \frac{r^2}{8r_0^3}\left(2 - \frac{r}{r_0}\right)^2\left(-\frac{1}{r_0}\right)e^{-\frac{r}{r_0}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

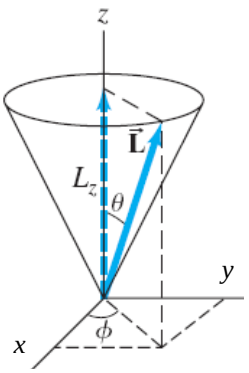


$$= \frac{(2r_0 - r)re^{-\frac{r}{r_0}}}{8r_0^6}\left(r^2 - 6r_0 r + 4r_0^2\right) = 0 \quad \rightarrow \quad r = 0,\ r = 2r_0,\ r^2 - 6r_0 r + 4r_0^2 = 0$$

$$r^2 - 6r_0 r + 4r_0^2 = 0 \quad \rightarrow \quad r = \frac{6r_0 \pm \sqrt{36r_0^2 - 16r_0^2}}{2} = \left(3 \pm \sqrt{5}\right)r \approx 0.764r_0,\ 5.24r_0$$

So there are four extrema: $r = 0,\ 0.76r_0,\ 2r_0,\ 5.2r_0$. From Figure 39-8 we see that the most probable distance is $r = \boxed{5.2r_0}$.

68. The "location" of the beam is uncertain in the transverse direction by an amount equal to the aperture opening, D. This gives a value for the uncertainty in the transverse momentum. The momentum must be at least as big as its uncertainty, and so we obtain a value for the transverse momentum.



$$\Delta p_y \Delta y \geq \hbar \quad \rightarrow \quad \Delta p_y \geq \frac{\hbar}{\Delta y} = \frac{\hbar}{D} \quad \rightarrow \quad p_y \approx \frac{\hbar}{D}$$

The momentum in the forward direction is related to the wavelength of the light by $p_x = \frac{h}{\lambda}$. See the diagram to relate the momentum to the angle.

$$\theta \approx \frac{p_y}{p_x} \approx \frac{\hbar/D}{h/\lambda} = \frac{\lambda}{2\pi D} \ ; \text{ "spread"} = 2\theta = \frac{\lambda}{\pi D} \approx \boxed{\frac{\lambda}{D}}$$

69. The magnitude of the angular momentum is given by Eq. 39-3, and L_z is given by Eq. 39-4. The cosine of the angle between $\vec{\mathbf{L}}$ and the z axis is found from L and L_z.

$$L = \sqrt{\ell(\ell+1)}\hbar \ ; \ L_z = m_\ell \hbar \ ; \ \theta = \cos^{-1}\frac{L_z}{L} = \cos^{-1}\frac{m_\ell}{\sqrt{\ell(\ell+1)}}$$

(*a*) For $\ell = 1,\ m_\ell = -1,\ 0,\ 1$.

$$\theta_{1,1} = \cos^{-1}\frac{1}{\sqrt{2}} = \boxed{45°} \ ; \ \theta_{1,0} = \cos^{-1}\frac{0}{\sqrt{2}} = \boxed{90°} \ ;$$

$$\theta_{1,-1} = \cos^{-1}\frac{-1}{\sqrt{2}} = \boxed{135°}$$

(*b*) For $\ell = 2,\ m_\ell = -2, -1,\ 0,\ 1,\ 2$.

$$\theta_{2,2} = \cos^{-1}\frac{2}{\sqrt{6}} = \boxed{35.3°} \ ; \ \theta_{2,1} = \cos^{-1}\frac{1}{\sqrt{6}} = \boxed{65.9°} \ ; \ \theta_{2,0} = \cos^{-1}\frac{0}{\sqrt{2}} = \boxed{90°}$$

$$\theta_{2,-1} = \cos^{-1}\frac{-1}{\sqrt{6}} = \boxed{114.1°} \ ; \ \theta_{2,2} = \cos^{-1}\frac{-2}{\sqrt{6}} = \boxed{144.7°}$$

(*c*) For $\ell = 3,\ m_\ell = -3, -2, -1,\ 0,\ 1,\ 2,\ 3$.

$$\theta_{3,3} = \cos^{-1}\frac{3}{\sqrt{12}} = \boxed{30°} \ ; \ \theta_{3,2} = \cos^{-1}\frac{2}{\sqrt{12}} = \boxed{54.7°} \ ; \ \theta_{3,1} = \cos^{-1}\frac{1}{\sqrt{12}} = \boxed{73.2°}$$

$$\theta_{3,0} = \cos^{-1}\frac{0}{\sqrt{12}} = \boxed{90°} \ ; \ \theta_{3,-1} = \cos^{-1}\frac{-1}{\sqrt{12}} = \boxed{106.8°} \ ; \ \theta_{3,-2} = \cos^{-1}\frac{-2}{\sqrt{12}} = \boxed{125.3°} \ ;$$

$$\theta_{3,-3} = \cos^{-1}\frac{-3}{\sqrt{12}} = \boxed{150°}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*d*) We see from the previous parts that the smallest angle occurs for $m_\ell = \ell$.

$$\theta_{100,100} = \cos^{-1}\frac{100}{\sqrt{(100)(101)}} = \boxed{5.71^\circ}$$

$$\theta_{10^6,10^6} = \cos^{-1}\frac{10^6}{\sqrt{(10^6)(10^6+1)}} = \boxed{0.0573^\circ}$$

This is consistent with the correspondence principle, which would say that the angle between $\vec{\mathbf{L}}$ and the *z* axis could be any value classically, which is represented by letting $\ell \to \infty$ (which also means $n \to \infty$).

70. (*a*) Since $\Delta L_z = 0$, $\Delta\phi \to \infty$, and so $\boxed{\phi \text{ is unknown}}$. We can say nothing about the value of ϕ.

(*b*) Since ϕ is completely unknown, we have no knowledge of the component of the angular momentum perpendicular to the *z*-axis. Thus $\boxed{L_x \text{ and } L_y \text{ are unknown}}$.

(*c*) The square of the total angular momentum is given by $L^2 = L_x^2 + L_y^2 + L_z^2$. Use this with the quantization conditions for L and L_z given in Eqs. 39-3 and 39-4.

$$L^2 = L_x^2 + L_y^2 + L_z^2 \;\rightarrow\; \ell(\ell+1)\hbar^2 = L_x^2 + L_y^2 + m_\ell^2\hbar^2 \;\rightarrow\; L_x^2 + L_y^2 = \left[\ell(\ell+1) - m_\ell^2\right]\hbar^2$$

$$\sqrt{L_x^2 + L_y^2} = \boxed{\left[\ell(\ell+1) - m_\ell^2\right]^{1/2}\hbar}$$

71. (*a*) The mean value can be found as described in Problem 19. We use the first definite integral given in Appendix B-5, with *n* = 1 and *a* = 1.

$$\overline{\left(\frac{1}{r}\right)} = \int_0^\infty \frac{1}{r}|\psi_{100}|^2 4\pi r^2 dr = \int_0^\infty \frac{1}{r}\frac{1}{\pi r_0^3} e^{-2\frac{r}{r_0}} 4\pi r^2 dr = \frac{4}{r_0^2}\int_0^\infty \frac{r}{r_0} e^{-2\frac{r}{r_0}} dr \text{ ; let } x = 2\frac{r}{r_0} \;\rightarrow$$

$$= \frac{1}{r_0}\int_0^\infty x e^{-x} dx = \frac{1}{r_0}(1) = \frac{1}{r_0}$$

$$U = -\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r} \;\rightarrow\; \bar{U} = -\frac{e^2}{4\pi\varepsilon_0}\int_0^\infty \frac{1}{r}|\psi_{100}|^2 4\pi r^2 dr = \boxed{-\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r_0}}$$

(*b*) For the ground state of hydrogen, Eq. 37-14a gives the energy, and Eq. 37-11 gives the Bohr radius. Substitute those expressions into $E = \bar{U} + \bar{K}$.

$$E = -\frac{e^4 m}{8\varepsilon_0^2 h^2} \;;\; \bar{U} = -\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r_0}$$

$$\bar{K} = E - \bar{U} = -\frac{e^4 m}{8\varepsilon_0^2 h^2} - \left(-\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r_0}\right) = \frac{e^2}{4\pi\varepsilon_0 r_0} - \frac{e^4 m}{8\varepsilon_0^2 h^2} = \frac{e^2}{4\pi\varepsilon_0 r_0} - \frac{e^4 m\left(\frac{h^2\varepsilon_0}{\pi m e^2}\right)}{8\varepsilon_0^2 h^2 r_0}$$

$$= \frac{e^2}{4\pi\varepsilon_0 r_0} - \frac{e^2}{8\pi\varepsilon_0 r_0} = \frac{e^2}{8\pi\varepsilon_0 r_0} = \boxed{-\tfrac{1}{2}\bar{U}}$$

72. In the Bohr model, $L_{\text{Bohr}} = n\frac{h}{2\pi} = \boxed{2\hbar}$. In quantum mechanics, $L_{\text{QM}} = \sqrt{\ell(\ell+1)}\,\hbar$. For $n = 2$, $\ell = 0$ or $\ell = 1$, so that $L_{\text{QM}} = \sqrt{0(0+1)}\,\hbar = \boxed{0}$ or $L_{\text{QM}} = \sqrt{1(1+1)}\,\hbar = \boxed{\sqrt{2}\hbar}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

73. (*a*) The $4p \to 3p$ transition is $\boxed{\text{forbidden,}}$ because $\Delta\ell = 0 \neq \pm 1$.
(*b*) The $3p \to 1s$ transition is $\boxed{\text{allowed,}}$ because $\Delta\ell = -1$.
(*c*) The $4d \to 3d$ transition is $\boxed{\text{forbidden,}}$ because $\Delta\ell = 0 \neq \pm 1$.
(*d*) The $4d \to 3s$ transition is $\boxed{\text{forbidden,}}$ because $\Delta\ell = -2 \neq \pm 1$.
(*e*) The $4s \to 2p$ transition is $\boxed{\text{allowed,}}$ because $\Delta\ell = +1$.

74. The binding energy is given by the opposite of Eq. 37-14b.

$$-E_n = (13.6\text{eV})\frac{Z^2}{n^2} = \frac{13.6\text{eV}}{45^2} = \boxed{6.72\times10^{-3}\text{eV}}$$

The radius is given by Eq. 37-13.

$$r_n = \frac{n^2}{Z}\left(0.529\times10^{-10}\text{m}\right) = 45^2\left(0.529\times10^{-10}\text{m}\right) = \boxed{1.07\times10^{-7}\text{m}}$$

The effective cross-sectional area is as follows.

$$\sigma = \pi r^2 = \pi\left(1.07\times10^{-7}\text{m}\right)^2 = \boxed{3.60\times10^{-14}\text{m}^2}$$

75. The wavelengths of emitted lines from one-electron atoms are given by Eq. 37-15. We can simplify the equation by using the Rydberg constant, so $\frac{1}{\lambda} = Z^2R\left(\frac{1}{n'^2} - \frac{1}{n^2}\right)$. The Lyman series with hydrogen has $Z = 1$ and $n' = 1$. Every fourth line from the unknown element match the wavelengths of the first three Lyman lines. This gives three equations in three unknowns.

$$\frac{1}{\lambda_{\substack{\text{Lyman}\\2\to1}}} = R\left(\frac{1}{1^2} - \frac{1}{2^2}\right) = Z^2R\left(\frac{1}{n^2} - \frac{1}{m^2}\right) \quad\to\quad \frac{3}{4} = Z^2\left(\frac{1}{n^2} - \frac{1}{m^2}\right)$$

$$\frac{1}{\lambda_{\substack{\text{Lyman}\\3\to1}}} = R\left(\frac{1}{1^2} - \frac{1}{3^2}\right) = Z^2R\left(\frac{1}{n^2} - \frac{1}{(m+4)^2}\right) \quad\to\quad \frac{8}{9} = Z^2\left(\frac{1}{n^2} - \frac{1}{(m+4)^2}\right)$$

$$\frac{1}{\lambda_{\substack{\text{Lyman}\\4\to1}}} = R\left(\frac{1}{1^2} - \frac{1}{4^2}\right) = Z^2R\left(\frac{1}{n^2} - \frac{1}{(m+8)^2}\right) \quad\to\quad \frac{15}{16} = Z^2\left(\frac{1}{n^2} - \frac{1}{(m+8)^2}\right)$$

Subtract the first equation from each of the other two equations.

$$\frac{8}{9} - \frac{3}{4} = Z^2\left(\frac{1}{n^2} - \frac{1}{(m+4)^2}\right) - Z^2\left(\frac{1}{n^2} - \frac{1}{m^2}\right) \quad\to\quad \frac{5}{36} = Z^2\left(\frac{1}{m^2} - \frac{1}{(m+4)^2}\right)$$

$$\frac{15}{16} - \frac{3}{4} = Z^2\left(\frac{1}{n^2} - \frac{1}{(m+8)^2}\right) - Z^2\left(\frac{1}{n^2} - \frac{1}{m^2}\right) \quad\to\quad \frac{3}{16} = Z^2\left(\frac{1}{m^2} - \frac{1}{(m+8)^2}\right)$$

Divide the resulting equations to eliminate *Z*, solve for *m*, and then substitute to find *Z*.

$$\frac{\frac{5}{36}}{\frac{3}{16}} = \frac{Z^2\left(\frac{1}{m^2} - \frac{1}{(m+4)^2}\right)}{Z^2\left(\frac{1}{m^2} - \frac{1}{(m+8)^2}\right)} \quad\to\quad \frac{20}{27} = \frac{\frac{(m+4)^2 - m^2}{m^2(m+4)^2}}{\frac{(m+8)^2 - m^2}{m^2(m+8)^2}} = \frac{(m+2)(m+8)^2}{2(m+4)^3} \quad\to$$

$$40(m+4)^3 = 27(m+2)(m+8)^2 \quad\to\quad 13m^3 + 514m^2 + 608m - 896 = 0$$

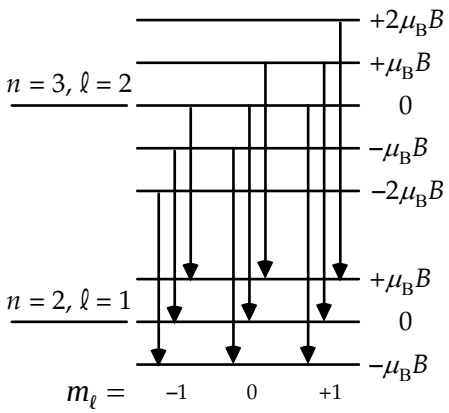
This is a cubic equation, which can be solved by numerical techniques. We first drew a graph, and saw that two of the 0's of the function were negative, and one was near $m = 8$. The only acceptable results are for $m > 0$, and substitution verifies that $m = 8$ solves the equation. We use that result to find Z.

$$\frac{3}{16} = Z^2\left(\frac{1}{m^2} - \frac{1}{(m+8)^2}\right) \quad \rightarrow \quad Z = \sqrt{\left(\frac{3}{16}\right)\left(\frac{1}{m^2} - \frac{1}{(m+8)^2}\right)^{-1}} = \sqrt{\left(\frac{3}{16}\right)\left(\frac{1}{8^2} - \frac{1}{(8+8)^2}\right)^{-1}} = 4$$



Thus the element is beryllium. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH39.XLS," on tab "Problem 39.75."

76. (*a*) The additional energy due to the presence of a magnetic field is derived in Section 39-7, as $U = \mu_B m_\ell B_z$. We use this to calculate the energy spacing between adjacent m_ℓ values.

$$U = \mu_B m_\ell B_z \quad \rightarrow$$

$$U = \mu_B B_z \Delta m_\ell = \frac{\left(9.27\times10^{-24}\,\text{J/T}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)}(1.6\,\text{T}) = 9.27\times10^{-5}\,\text{eV} \approx \boxed{9.3\times10^{-5}\,\text{eV}}$$

(*b*) As seen in Figure 39-4, the $n = 3$, $\ell = 2$ level will split into 5 levels, and the $n = 2$, $\ell = 1$ level will split into 3 levels. With no restrictions, there would be 15 different transitions possible. All transitions would have the same $\Delta n = 1$. Thus there are only three unique wavelengths possible: the one corresponding to a transition with $\Delta m_\ell = +1$ (a slightly larger energy change than in the $B = 0$ case), the one corresponding to a transition with $\Delta m_\ell = 0$ (the same energy change as in the $B = 0$ case), and the one corresponding to a transition with $\Delta m_\ell = -1$ (a slightly smaller energy change than in the $B = 0$ case). See the diagram, showing 9 possible transitions grouped into 3 actual energy changes. The value along the right side is the change in energy level due to the magnetic field interaction.

(*c*) Eq. 37-15 gives the wavelength for hydrogen, considering only a change in principal quantum number. The energies for those transitions is on the order of eV. The energy change due to the magnetic field interaction is much smaller than that, so we can use an approximation, knowing ΔE from part (*a*). We obtain E from Eq. 37-14b.

$$\lambda_{n=3\rightarrow2} = \left[R\left(\frac{1}{2^2} - \frac{1}{3^2}\right)\right]^{-1} = \left[1.0974\times10^7\,\text{m}^{-1}\left(\tfrac{1}{4} - \tfrac{1}{9}\right)\right]^{-1} = 6.56096\times10^{-7}\,\text{m} \approx 656.10\,\text{nm}$$

$$\lambda = h\frac{c}{E} \quad \rightarrow \quad \Delta\lambda = -\frac{hc}{E^2}\Delta E = -\lambda\frac{\Delta E}{E} \quad ; \quad E_{n=3\rightarrow2} = 13.6\,\text{eV}\left(\frac{1}{2^2} - \frac{1}{3^2}\right) = 1.889\,\text{eV}$$

$$\Delta\lambda = -\lambda\frac{\Delta E}{E} = -(656.10\,\text{nm})\left(\frac{9.27\times10^{-5}\,\text{eV}}{1.889\,\text{eV}}\right) = 0.032\,\text{nm}$$

$$\lambda_{\Delta m_\ell=+1} = \lambda_{n=3\rightarrow2} + \Delta\lambda = 656.10\,\text{nm} - 0.032\text{nm} = \boxed{656.07\,\text{nm}}$$

$$\lambda_{\Delta m_\ell=+1} = \lambda_{n=3\rightarrow2} + 0 = \boxed{656.10\,\text{nm}}$$

$$\lambda_{\Delta m_\ell=-1} = \lambda_{n=3\rightarrow2} + \Delta\lambda = 656.10\,\text{nm} + 0.032\text{nm} = \boxed{656.13\,\text{nm}}$$

77. (*a*) We use Eq. 39-16b, with the "note" as explained in the problem, multiplying the initial expression times $\frac{8}{2}$.

$$\frac{N_2}{N_1} = \tfrac{8}{2} e^{-\left(\frac{E_2 - E_1}{kT}\right)} = \tfrac{8}{2} e^{-\left[\frac{\left(\frac{-13.6\text{eV}}{4} - \frac{-13.6\text{eV}}{1}\right)\left(1.60\times10^{-19}\text{J/eV}\right)}{\left(1.38\times10^{-23}\text{J/K}\right)(300\text{K})}\right]} = 4e^{-394.2}$$

Many calculators will not directly evaluate $e^{-394.2}$, so we do the following.

$$x = e^{-394.2} \;\; ; \;\; \log x = -394.2 \log e = -394.2(0.4343) = -171.2 \;\; ;$$

$$x = 10^{-171.2} = 10^{-0.2} 10^{-171} = 0.631\times10^{-171}$$

$$\frac{N_2}{N_1} = 4e^{-394.2} = 4\left(0.631\times10^{-171}\right) = 2.52\times10^{-171} \approx \boxed{3\times10^{-171}}$$

There are 18 states with $n = 3$, so we multiply by $\frac{18}{2}$.

$$\frac{N_3}{N_1} = \tfrac{18}{2} e^{-\left(\frac{E_3 - E_1}{kT}\right)} = \tfrac{18}{2} e^{-\left[\frac{\left(\frac{-13.6\text{eV}}{9} - \frac{-13.6\text{eV}}{1}\right)\left(1.60\times10^{-19}\text{J/eV}\right)}{\left(1.38\times10^{-23}\text{J/K}\right)(300\text{K})}\right]} = 9e^{-467.2} = 1.13\times10^{-202} \approx \boxed{1\times10^{-202}}$$

(*b*) We repeat the evaluations for the higher temperature.

$$\frac{N_2}{N_1} = \tfrac{8}{2} e^{-\left(\frac{E_2 - E_1}{kT}\right)} = \tfrac{8}{2} e^{-\left[\frac{\left(\frac{-13.6\text{eV}}{4} - \frac{-13.6\text{eV}}{1}\right)\left(1.60\times10^{-19}\text{J/eV}\right)}{\left(1.38\times10^{-23}\text{J/K}\right)(6000\text{K})}\right]} = 4e^{-19.71} = 1.10\times10^{-8} \approx \boxed{1\times10^{-8}}$$

$$\frac{N_3}{N_1} = \tfrac{18}{2} e^{-\left(\frac{E_3 - E_1}{kT}\right)} = \tfrac{18}{2} e^{-\left[\frac{\left(\frac{-13.6\text{eV}}{9} - \frac{-13.6\text{eV}}{1}\right)\left(1.60\times10^{-19}\text{J/eV}\right)}{\left(1.38\times10^{-23}\text{J/K}\right)(6000\text{K})}\right]} = 9e^{-23.36} = 6.44\times10^{-10} \approx \boxed{6\times10^{-10}}$$

(*c*) Since the fraction of atoms in each excited state is very small, we assume that N_1 is the number of hydrogen atoms given. 1.0 g of H atoms contains 6.02×10^{23} atoms.

$$N_2 = N_1\left(1.10\times10^{-8}\right) = \left(6.02\times10^{23}\right)\left(1.10\times10^{-8}\right) = 6.62\times10^{15} \approx \boxed{7\times10^{15}}$$

$$N_3 = N_1\left(6.44\times10^{-10}\right) = \left(6.02\times10^{23}\right)\left(6.44\times10^{-10}\right) = 3.88\times10^{14} \approx \boxed{4\times10^{14}}$$

(*d*) We assume the lifetime of an excited state atom is 10^{-8}s. Each atom would emit one photon as its electron goes to the ground state. The number of photons emitted per second can be estimated by the number of atoms, divided by the lifetime.

$$n_3 = \frac{N_3}{\tau} = \frac{4\times10^{14}}{10^{-8}\text{s}} \boxed{4\times10^{22}\,\text{photons/s}} \;\; ; \;\; n_2 = \frac{N_2}{\tau} = \frac{7\times10^{15}}{10^{-8}\text{s}} \approx \boxed{7\times10^{23}\,\text{photons/s}}$$

CHAPTER 40: Molecules and Solids

Responses to Questions

1. (*a*) Covalent; (*b*) ionic; (*c*) metallic.

2. A neutral calcium atom has 20 electrons. Its outermost electrons are in the $4s^2$ state. The inner 18 electrons form a spherically symmetric distribution and partially shield the outer two electrons from the nuclear charge. A neutral chlorine atom has 17 electrons; it lacks just one electron to have its outer shell filled. A $CaCl_2$ molecule could be formed when the outer two electrons of the calcium atom are "shared" with two chlorine atoms. These electrons will be attracted by both the Ca and the Cl nuclei and will spend part of their time between the Ca and Cl nuclei. The nuclei will be attracted to this negatively charged area, forming a covalent bond. As is the case with other asymmetric covalent bonds, this bond will have a partial ionic character as well. The two electrons will partly orbit the Ca nucleus and partly orbit each of the two Cl nuclei. Since each Cl nucleus will now have an extra electron part of the time, it will have a net negative charge. The Ca nucleus will "lose" two electrons for part of the time, giving it a net positive charge.

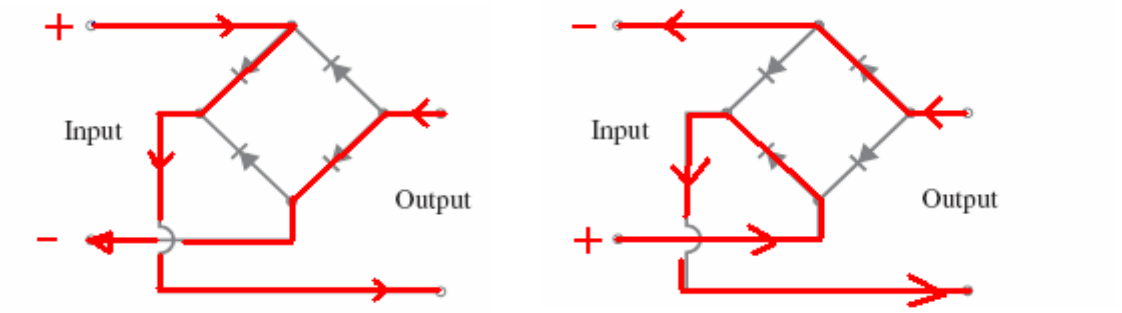
3. No, neither the H_2 nor the O_2 molecule has a permanent dipole moment. The outer electrons are shared equally between the two atoms in each molecule, so there are no polar ends that are more positively or negatively charged. The H_2O molecule does have a permanent dipole moment. The electrons associated with the hydrogen atoms are pulled toward the oxygen atom, leaving each hydrogen with a small net positive charge and the oxygen with a small net negative charge. Because of the shape of the H_2O molecule (see Figure 40-6), one end of the molecule will be positive and the other end will be negative, resulting in a permanent dipole moment.

4. The molecule H_3 has three electrons. According to the Pauli exclusion principle, no two of these electrons can be in the same quantum state. Two of them will be $1s^2$ electrons and will form a "closed shell" and a spherically symmetric distribution, and the third one will be outside this distribution and unpaired. This third electron will be partially shielded from the nucleus and will thus be easily "lost," resulting in an unstable molecule. The ion H_3^+ only has two electrons. These $1s^2$ electrons will form a closed shell and a spherically symmetric distribution, resulting in a stable configuration.

5. The energy of a molecule can be divided into four categories: translational kinetic energy, rotational kinetic energy, vibrational kinetic energy, and electrostatic potential energy.

6. Yes. The electron will spend most of its time between the two nuclei. Both positive nuclei will be attracted to this negative charge, forming a bond.

7. The carbon atom ($Z = 6$) usually forms four bonds because carbon requires four electrons to form a closed $2p$ shell, and each hydrogen-like atom contributes one electron.



8. The last valence electron of a sodium atom is shielded from most of the sodium nuclear charge and experiences a net nuclear charge of $+1e$. The outer shell of a chlorine atom is the $3p$ shell, which contains five electrons. Due to shielding effects, the $3p$ electrons of chlorine experience a net nuclear charge of $+5e$. In NaCl, the last valence electron of sodium is strongly bound to a chlorine nucleus. This strong ionic bonding produces a large energy gap between the valence band and the conduction band in NaCl, characteristic of a good insulator.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9. The conduction electrons are not strongly bound to particular nuclei, so a metal can be viewed as a collection of positive ions and a negative electron "gas." (The positive ions are just the metal atoms without their outermost electrons, since these "free" electrons make up the gas.) The electrostatic attraction between the freely-roaming electrons and the positive ions keeps the electrons from leaving the metal.

10. As temperature increases, the thermal motion of ions in a metal lattice will increase. More electrons will collide with the ions, increasing the resistivity of the metal. When the temperature of a semiconductor increases, more electrons are able to move into the conduction band, making more charge carriers available and therefore decreasing the resistivity. (Note: the thermal motion increases in semiconductors as well, but the increase in the number of charge carriers is a larger effect.)

11. When the top branch of the input circuit is at the high voltage (current is flowing in this direction for half the cycle), then the bottom branch of the output is at the high voltage. The current follows the path through the bridge in the diagram on the left. When the bottom branch of the input circuit is at the high voltage (current is flowing in this direction during the other half of the cycle), then the bottom branch of the output is still at high voltage. The current follows the path through the bridge in the diagram on the right.

12. In an ideal gas, it is possible for all of the gas particles to have the same energy. (The velocity distribution of the particles in an ideal gas usually follows the Maxwell velocity distribution.) As the temperature of the gas increases, the kinetic energy of the gas increases. In a Fermi electron gas, only two electrons can have the same energy (Pauli exclusion principle). The electrons fill up the energy states up to the Fermi level. As the temperature of the Fermi gas increases, only the electrons in the top few levels can move to higher energy levels. The result is that the energy of the Fermi gas is not strongly temperature dependent.

13. For an ideal *pn* junction diode connected in reverse bias, the holes and electrons that would normally be near the junction are pulled apart by the reverse voltage, preventing current flow across the junction. The resistance is essentially infinite. A real diode does allow a small amount of reverse current to flow if the voltage is high enough, so the resistance in this case is very high but not infinite. A *pn* junction diode connected in forward bias has a low resistance (the holes and electrons are close together at the junction) and current flows easily.

14. The general shape of Figure 40-28 is the same for most metals. The scale of the graph (especially the x-axis scale and the Fermi energy) is peculiar to copper and will change from metal to metal.

15. The base current (between the base and the emitter) controls the collector current (between the collector and the emitter). If there is no base current, then no collector current flows. Thus, controlling the relatively small base current allows the transistor to act as a switch, turning the larger collector current on and off.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

16. The main difference between *n*-type and *p*-type semiconductors is the sign on the charge carriers. In an *n*-type semiconductor the charge carriers are negative electrons. In a *p*-type semiconductor, the charge carriers are positive holes.

17. A transistor can be used as an amplifier because small changes in the base current can make much larger changes in the collector current. (See Figure 40-43.) For a *pnp* transistor, both the collector and the base voltages are negative, and holes move from the emitter to the collector. The diagram for a *pnp* amplifier looks just like Figure 40-43, with the polarity of $\mathscr{E}_B$ and $\mathscr{E}_C$ reversed, I_B and I_C flowing in opposite directions, and the emitter arrow pointing toward the base.

18. In Figure 40-43, the base–collector junction is reverse-biased and the base–emitter junction is forward-biased.

19. The energy comes from the power supplied by the collector/emitter voltage source. The input signal to the base just regulates how much current, and therefore power, can be drawn from the collector's voltage source.

20. The phosphorus atoms will be donor atoms. Phosphorus has five valence electrons. It will form four covalent bonds with the silicon atoms around it, and will have one "extra" electron which is weakly bound to the atom and can be easily excited up to the conduction band. This process results in extra electrons in the conduction band. Silicon doped with phosphorus is therefore an *n*-type semiconductor.

21. No. Ohmic devices (those that obey Ohm's law) have a constant resistance and therefore a linear relationship between voltage and current. The voltage-current relationship for diodes is not linear. The resistance of a diode operated in reverse-bias is very large. The same diode operated in a forward-bias mode has a much smaller resistance. Since a transistor can be thought of as made up of diodes, it is also non-ohmic.

22. No. Single diodes can be used to rectify signals, but cannot amplify signals. The diode will allow the signal to pass, if forward-biased, or not allow the signal to pass, if reverse-biased. Combinations of diodes with additional power sources, as in a transistor, are able to amplify a signal.

23. Reversing the collector voltage would reverse the roles of the collector and emitter of the transistor. Unless the base-emitter voltage is also reversed, the transistor cannot act as an amplifier.

Solutions to Problems

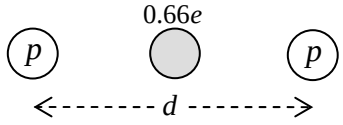
Note: A factor that appears in the analysis of electron energies is

$$\frac{e^2}{4\pi\varepsilon_0} = \left(9.00\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(1.60\times10^{-19}\,\text{C}\right)^2 = 2.30\times10^{-28}\,\text{J}\cdot\text{m}.$$

1. We calculate the binding energy as the opposite of the electrostatic potential energy. We use Eq. 23-10 for the potential energy.

$$\text{Binding energy} = -U = -\frac{1}{4\pi\varepsilon_0}\frac{Q_1Q_2}{r} = -\frac{e^2}{4\pi\varepsilon_0}\left(\frac{1}{0.28\times10^{-9}\,\text{m}}\right) = -\frac{2.30\times10^{-28}\,\text{J}\cdot\text{m}}{0.28\times10^{-9}\,\text{m}}$$

$$= 8.214\times10^{-19}\,\text{J} \approx \boxed{8.2\times10^{-19}\,\text{J}}$$



$$= 8.214\times10^{-19}\,\text{J}\left(\frac{1\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = 5.134\,\text{eV} \approx \boxed{5.1\text{eV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2. From Problem 1, the "point electron" binding energy is 5.134 eV. With the repulsion of the electron clouds included, the actual binding energy is 4.43 eV. Use these values to calculate the contribution of the electron clouds.

$$5.134\,\text{eV} - 4.43\,\text{eV} = 0.704\,\text{eV} \approx \boxed{0.70\,\text{eV}}$$

3. We calculate the binding energy as the difference between the energy of two isolated hydrogen atoms and the energy of the bonded combination of particles. We estimate the energy of the bonded combination as the negative potential energy of the two electron-proton combinations, plus the positive potential energy of the proton-proton combination. We approximate the electrons as a single object with a charge of 0.33 of the normal charge of two electrons, since the electrons only spend that fraction of time between the nuclei. A simple picture illustrating our bonded model is shown.

$$U_{\text{isolated}} = 2(-13.6\,\text{eV}) = -27.2\,\text{eV}$$

$$U_{\text{bonded}} = U_{\text{p-p}} + 2U_{\text{e-p}} = \frac{e^2}{4\pi\varepsilon_0}\left(\frac{1}{d}\right) - 2\left[\frac{e(0.66)e}{4\pi\varepsilon_0}\left(\frac{1}{\frac{1}{2}d}\right)\right] = \frac{e^2}{4\pi\varepsilon_0}\frac{1}{d}(1-2.64)$$

$$= (-1.64)\frac{\left(2.30\times10^{-28}\,\text{J}\bullet\text{m}\right)}{\left(0.074\times10^{-9}\,\text{m}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = -31.9\,\text{eV}$$

$$U_{\text{binding}} = U_{\text{isolated}} - U_{\text{bonded}} = -27.2\,\text{eV} - (-31.9\,\text{eV}) = \boxed{4.7\,\text{eV}}$$

This is reasonably close to the actual value of 4.5 eV quoted in the text.

4. We follow the procedure outlined in the statement of the problem.

HN: $\frac{1}{2}\left(d_{\text{H}_2} + d_{\text{N}_2}\right) = \frac{1}{2}(74\,\text{pm} + 145\,\text{pm}) = \boxed{110\,\text{pm}}$

CN: $\frac{1}{2}\left(d_{\text{C}_2} + d_{\text{N}_2}\right) = \frac{1}{2}(154\,\text{pm} + 145\,\text{pm}) = \boxed{150\,\text{pm}}$

NO: $\frac{1}{2}\left(d_{\text{N}_2} + d_{\text{O}_2}\right) = \frac{1}{2}(145\,\text{pm} + 121\,\text{pm}) = \boxed{133\,\text{pm}}$

5. According to the problem statement, 5.39 eV of energy is required to make an Li^+ ion from neutral Li, and 3.41 eV of energy is released when an F atom becomes an F^- ion. That means that a net energy input of 5.39 eV – 3.41 eV = 1.98 eV is needed to form the ions. We calculate the negative potential energy of the attraction between the two ions.

$$U = -\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r} = -\frac{\left(2.30\times10^{-28}\,\text{J}\cdot\text{m}\right)}{\left(0.156\times10^{-9}\,\text{m}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = -9.21\,\text{eV}$$

The binding energy should therefore be 9.21 eV – 1.98 eV = 7.23 eV. But the actual binding energy is only 5.95 eV. Thus the energy associated with the repulsion of the electron clouds is 7.23 eV – 5.95 eV = $\boxed{1.28\ \text{eV}}$.

6. We convert the units from kcal/mole to eV/molecule.

$$1\frac{\text{kcal}}{\text{mole}}\times\frac{4186\,\text{J}}{1\,\text{kcal}}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}\times\frac{1\,\text{mole}}{6.022\times10^{23}\,\text{molecules}} = \boxed{4.339\times10^{-2}\,\frac{\text{eV}}{\text{molecule}}}$$

Now convert 4.43 eV per molecule into kcal per mole.

$$4.43\frac{\text{eV}}{\text{molecule}}\times\frac{1\,\text{kcal/mol}}{4.339\times10^{-2}\,\text{eV/molecule}} = \boxed{102\,\text{kcal/mol}}$$

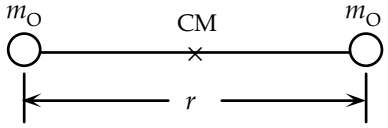
7. (*a*) The neutral He atom has two electrons in the ground state, $n=1$, $\ell=0$, $m_\ell=0$. Thus the two electrons have opposite spins, $m_s=\pm\frac{1}{2}$. If we try to form a covalent bond, we see that an electron from one of the atoms will have the same quantum numbers as one of the electrons on the other atom. From the exclusion principle, this is not allowed, so the electrons cannot be shared.

(*b*) We consider the He_2^+ molecular ion to be formed from a neutral He atom and an He^+ ion. It will have three electrons. If the electron on the ion has a certain spin value, it will have the opposite spin as one of the electrons on the neutral atom. Thus those two electrons can be in the same spatial region, and so a bond can be formed.

8. The units of $\dfrac{\hbar^2}{I}$ are $\dfrac{(\text{J}\bullet\text{s})^2}{(\text{kg}\bullet\text{m}^2)}=\dfrac{\text{J}^2}{(\text{kg}\bullet\text{m/s}^2)\text{m}}=\dfrac{\text{J}^2}{(\text{N}\bullet\text{m})}=\dfrac{\text{J}^2}{\text{J}}=\text{J}$.



9. The reduced mass is given in Section 40-4 as $\mu=\dfrac{m_1m_2}{m_1+m_2}$. We calculate in atomic mass units.

(*a*) KCl: $\mu=\dfrac{m_1m_2}{m_1+m_2}=\dfrac{(39.10\,\text{u})(35.45\,\text{u})}{(39.10\,\text{u})+(35.45\,\text{u})}=\boxed{18.59\,\text{u}}$

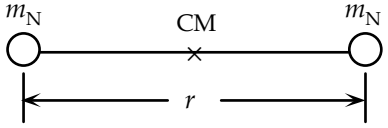
(*b*) O_2: $\mu=\dfrac{m_1m_2}{m_1+m_2}=\dfrac{(16.00\,\text{u})(16.00\,\text{u})}{(16.00\,\text{u})+(16.00\,\text{u})}=\boxed{8.00\,\text{u}}$

(*c*) HCl: $\mu=\dfrac{m_1m_2}{m_1+m_2}=\dfrac{(1.008\,\text{u})(35.45\,\text{u})}{(1.008\,\text{u})+(35.45\,\text{u})}=\boxed{0.9801\,\text{u}}$

10. (*a*) The moment of inertia of O_2 about its CM is given by

$$I=2m_O\left(\frac{r}{2}\right)^2=\frac{m_Or^2}{2}.$$

$$\frac{\hbar^2}{2I}=\frac{\hbar^2}{m_Or^2}=\frac{(1.055\times10^{-34}\,\text{J}\bullet\text{s})^2}{(16)(1.66\times10^{-27}\,\text{kg})(0.121\times10^{-9}\,\text{m})^2(1.60\times10^{-19}\,\text{J/eV})}=1.789\times10^{-4}\,\text{eV}$$



$$\approx\boxed{1.79\times10^{-4}\,\text{eV}}$$

(*b*) From Figure 40-17, we see that the energy involved in the ℓ = 2 to ℓ = 1 transition is $\dfrac{2\hbar^2}{I}$.

$$\Delta E=\frac{2\hbar^2}{I}=4\frac{\hbar^2}{2I}=4(1.789\times10^{-4}\,\text{eV})=7.156\times10^{-4}\,\text{eV}\approx\boxed{7.16\times10^{-4}\,\text{eV}}$$

$$\Delta E=h\frac{c}{\lambda}\quad\rightarrow\quad\lambda=\frac{hc}{\Delta E}=\frac{(6.63\times10^{-34}\,\text{J}\bullet\text{s})(3.00\times10^8\,\text{m/s})}{(7.156\times10^{-4}\,\text{eV})(1.60\times10^{-19}\,\text{J/eV})}=\boxed{1.74\times10^{-3}\,\text{m}}$$

11. Use the rotational energy and the moment of inertia of N_2 about its CM to find the bond length.

$$I=2m_N\left(\frac{r}{2}\right)^2=\frac{m_Nr^2}{2};\ E_{\text{rot}}=\frac{\hbar^2}{2I}=\frac{\hbar^2}{m_Nr^2}\quad\rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$r = \frac{\hbar}{\sqrt{E_{\text{rot}} m_{\text{N}}}} = \frac{\left(1.055\times10^{-34}\ \text{J•s}\right)}{\sqrt{\left(2.48\times10^{-4}\text{eV}\right)\left(1.60\times10^{-19}\ \text{J/eV}\right)\left(14.01\text{u}\right)\left(1.66\times10^{-27}\ \text{kg/u}\right)}} = \boxed{1.10\times10^{-10}\text{m}}$$

12. The longest wavelength emitted will be due to the smallest energy change. From Figure 40-17, the smallest rotational energy change is $\Delta E = \hbar^2/I$. We find the rotational inertia from Eq. 40-4.

$$\Delta E = \frac{\hbar^2}{I} = \frac{hc}{\lambda} \quad \rightarrow$$

$$\lambda = \frac{hc}{\hbar^2} I = \frac{4\pi^2 c}{h}\left(\frac{m_1 m_2}{m_1 + m_2}\right) r^2$$

$$= \frac{4\pi^2\left(3.00\times10^8\ \text{m/s}\right)}{\left(6.63\times10^{-34}\text{J•s}\right)}\left[\frac{(6.941\text{u})(1.008\text{u})}{6.941\text{u}+1.008\text{u}}\right]\left(1.66\times10^{-27}\ \text{kg/u}\right)\left(0.16\times10^{-9}\text{m}\right)^2$$

$$= \boxed{6.7\times10^{-4}\text{m}}$$

13. The energies involved in the transitions are given in Figure 40-17. We find the rotational inertial from Eq. 40-4. The basic amount of rotational energy is $\hbar^2/I$.

$$\frac{\hbar^2}{I} = \frac{\hbar^2}{\left(\dfrac{m_1 m_2}{m_1 + m_2} r^2\right)} = \frac{\hbar^2}{\left(\frac{1}{2} m_{\text{H}} r^2\right)} = \frac{2\hbar^2}{m_{\text{H}} r^2} = \frac{2\left(1.055\times10^{-34}\ \text{J•s}\right)^2}{\left(1.008\text{u}\right)\left(1.66\times10^{-27}\ \text{kg/u}\right)\left(0.074\times10^{-9}\text{m}\right)^2}$$

$$= 2.429\times10^{-21}\text{J}$$

(*a*) For $\ell = 1$ to $\ell = 0$:

$$\Delta E = \frac{\hbar^2}{I} = 2.429\times10^{-21}\text{J}\left(\frac{1}{1.60\times10^{-19}\ \text{J/eV}}\right) = \boxed{1.5\times10^{-2}\text{eV}}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{\left(6.63\times10^{-34}\text{J•s}\right)\left(3.00\times10^8\ \text{m/s}\right)}{2.429\times10^{-21}\text{J}} = \boxed{8.2\times10^{-5}\text{m}}$$

(*b*) For $\ell = 2$ to $\ell = 1$:

$$\Delta E = 2\frac{\hbar^2}{I} = 2\left(2.429\times10^{-21}\text{J}\right)\left(\frac{1}{1.60\times10^{-19}\ \text{J/eV}}\right) = \boxed{3.0\times10^{-2}\text{eV}}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{\left(6.63\times10^{-34}\text{J•s}\right)\left(3.00\times10^8\ \text{m/s}\right)}{2\left(2.429\times10^{-21}\text{J}\right)} = \boxed{4.1\times10^{-5}\text{m}}$$

(*c*) For $\ell = 3$ to $\ell = 2$:

$$\Delta E = 3\frac{\hbar^2}{I} = 3\left(2.429\times10^{-21}\text{J}\right)\left(\frac{1}{1.60\times10^{-19}\ \text{J/eV}}\right) = \boxed{4.6\times10^{-2}\text{eV}}$$

$$\lambda = \frac{hc}{\Delta E} = \frac{\left(6.63\times10^{-34}\text{J•s}\right)\left(3.00\times10^8\ \text{m/s}\right)}{3\left(2.429\times10^{-21}\text{J}\right)} = \boxed{2.7\times10^{-5}\text{m}}$$

14. The energy change for transitions between combined rotational and vibrational states is given above Eq. 40-8a.

$$\Delta E = \Delta E_{\text{vib}} + \Delta E_{\text{rot}} = hf + \Delta E_{\text{rot}}$$

If $\Delta E = hf$ is to be in the spectrum, then $\Delta E_{\text{rot}} = 0$. But the selection rules state that $\Delta \ell = \pm 1$ for a transition. It is not possible to have $\Delta \ell = 0$ for a transition. The only way to have $\Delta E_{\text{rot}} = 0$ is for $\Delta \ell = 0,$ which is forbidden. Thus $\Delta E = hf$ is not possible. Here is a mathematical statement as well.

$$\Delta E_{\text{rot}} = E_{(\ell+\Delta\ell)} - E_\ell = (\ell + \Delta\ell)(\ell + \Delta\ell + 1)\frac{\hbar^2}{2I} - \ell(\ell+1)\frac{\hbar^2}{2I} = \Delta\ell(2\ell + \Delta\ell + 1)\frac{\hbar^2}{2I}$$

For $\Delta E_{\text{rot}} = 0,$ mathematically we must have $\Delta \ell = 0,$ which is forbidden.

15. (*a*) The reduced mass is defined in Eq. 40-4.

$$\mu = \frac{m_{\text{C}} m_{\text{O}}}{m_{\text{C}} + m_{\text{O}}} = \frac{(12.01\,\text{u})(16.00\,\text{u})}{(12.01\,\text{u}) + (16.00\,\text{u})} = \boxed{6.86\,\text{u}}$$

(*b*) We find the effective spring constant from Eq. 40-5.

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{\mu}} \quad \rightarrow$$

$$k = 4\pi f^2 \mu = 4\pi^2 \left(6.42 \times 10^{13}\,\text{Hz}\right)^2 (6.86\,\text{u})\left(1.66 \times 10^{-27}\,\text{kg/u}\right) = \boxed{1850\,\text{N/m}}$$

The spring constant for H_2 is estimated in Example 40-6 as 550 N/m.

$$\frac{k_{\text{CO}}}{k_{\text{H}_2}} = \frac{1850\,\text{N/m}}{550\,\text{N/m}} = \boxed{3.4}$$

16. The effective spring constant can be found from Eq. 40-5, using the vibrational frequency and the reduced mass.

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{\mu}} \quad \rightarrow \quad k = 4\pi f^2 \mu = 4\pi^2 f^2 \frac{m_1 m_2}{m_1 + m_2}$$

$$= 4\pi^2 \left(1.7 \times 10^{13}\,\text{Hz}\right)^2 \frac{(6.941\,\text{u})(79.904\,\text{u})}{(6.941\,\text{u} + 79.904\,\text{u})}\left(1.66 \times 10^{-27}\,\text{kg/u}\right) = \boxed{120\,\text{N/m}}$$

17. We first find the energies of the transitions represented by the wavelengths.

$$\Delta E_1 = \frac{hc}{\lambda} = \frac{\left(6.63 \times 10^{-34}\,\text{J•s}\right)\left(3.00 \times 10^8\,\text{m/s}\right)}{\left(1.60 \times 10^{-19}\,\text{J/eV}\right)\left(23.1 \times 10^{-3}\,\text{m}\right)} = 5.38 \times 10^{-5}\,\text{eV}$$

$$\Delta E_2 = \frac{hc}{\lambda} = \frac{\left(6.63 \times 10^{-34}\,\text{J•s}\right)\left(3.00 \times 10^8\,\text{m/s}\right)}{\left(1.60 \times 10^{-19}\,\text{J/eV}\right)\left(11.6 \times 10^{-3}\,\text{m}\right)} = 10.72 \times 10^{-5}\,\text{eV}$$

$$\Delta E_3 = \frac{hc}{\lambda} = \frac{\left(6.63 \times 10^{-34}\,\text{J•s}\right)\left(3.00 \times 10^8\,\text{m/s}\right)}{\left(1.60 \times 10^{-19}\,\text{J/eV}\right)\left(7.71 \times 10^{-3}\,\text{m}\right)} = 16.12 \times 10^{-5}\,\text{eV}$$

Since $\frac{\Delta E_2}{\Delta E_1} = \frac{10.72}{5.38} \approx 2$ and $\frac{\Delta E_3}{\Delta E_1} = \frac{16.12}{5.38} \approx 3,$ from the energy levels indicated in Figure 40-17, and from the selection rule that $\Delta \ell = \pm 1,$ we see that these three transitions must represent the $\ell = 1$ to $\ell = 0$ transition, the $\ell = 2$ to $\ell = 1$ transition, and the $\ell = 3$ to $\ell = 2$ transition. Thus $\Delta E_1 = \hbar^2 / I$. We use that relationship along with Eq. 40-4 to find the bond length.

$$\Delta E_1 = \frac{\hbar^2}{I} = \frac{\hbar^2}{\mu r^2} \quad \rightarrow$$

$$r = \frac{\hbar}{\sqrt{\mu \Delta E_1}} = \frac{\left(1.055\times10^{-34}\ \text{J•s}\right)}{\sqrt{\left[\frac{(22.990\,\text{u})(35.453\,\text{u})}{(22.990\,\text{u}+35.453\,\text{u})}\right]\left(1.66\times10^{-27}\ \text{kg/u}\right)\left(5.38\times10^{-5}\,\text{eV}\right)\left(1.60\times10^{-19}\ \text{J/eV}\right)}}$$

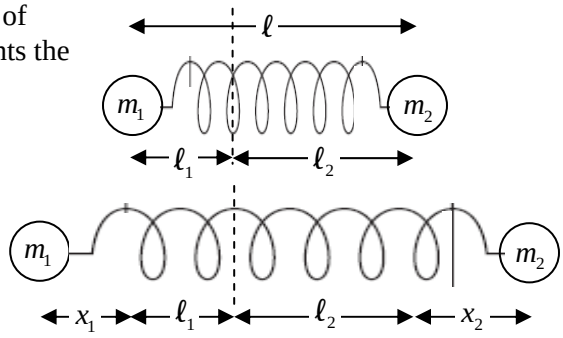
$$= \boxed{2.36\times10^{-10}\,\text{m}}$$

18. (*a*) The curve for $U = \frac{1}{2}k\left(x - r_0\right)^2 - 4.5\text{eV}$ is shown in Figure 40–18 as a dotted line. Measuring on the graph with a ruler gives the distance from the origin to the 0.1 nm mark as 38 mm. The measured distance from the origin to the largest *x*-intercept of the parabola is 45 mm. Taking a ratio gives the distance from the origin to the largest *x*-intercept as 0.118 nm. We fit a parabolic curve to data.

$$U = \tfrac{1}{2}k\left(x - r_0\right)^2 - 4.5\text{eV} \ ; \ U_{x=r_0} = \tfrac{1}{2}k\left(0\right)^2 - 4.5\text{eV} = -4.5\text{eV} \ \left(\text{check}\right)$$

$$U_{x=0.118\,\text{nm}} = \tfrac{1}{2}k\left(0.118\,\text{nm} - r_0\right)^2 - 4.5\text{eV} = 0 \quad \rightarrow$$

$$k = \frac{2\left(4.5\text{eV}\right)}{\left(0.118\,\text{nm} - 0.074\,\text{nm}\right)^2} = 4649\frac{\text{eV}}{\text{nm}^2}\left(\frac{1.60\times10^{-19}\,\text{J}}{\text{eV}}\right)\left(\frac{10^9\,\text{nm}}{1\text{m}}\right)^2 = 743.8\,\text{N/m}$$



$$\approx \boxed{740\,\text{N/m}}$$

(*b*) The frequency of vibration is given by Eq. 14-7a, using the reduced mass. Use this relationship to find the wavelength.

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{\mu}} = \frac{c}{\lambda} \quad \rightarrow$$

$$\lambda = 2\pi c\sqrt{\frac{\mu}{k}} = 2\pi\left(3.00\times10^8\ \text{m/s}\right)\sqrt{\frac{0.5\left(1.00794\,\text{u}\right)\left(1.66\times10^{-27}\ \text{kg/u}\right)}{743.8\,\text{N/m}}} = \boxed{2.0\times10^{-6}\,\text{m}}$$

19. Consider the system in equilibrium, to find the center of mass. See the first diagram. The dashed line represents the location of the center of mass.

$$\ell = \ell_1 + \ell_2 \ ; \ m_1\ell_1 = m_2\ell_2 = m_2\left(\ell - \ell_1\right) \quad \rightarrow$$

$$\ell_1 = \frac{m_2}{m_1 + m_2}\ell \ ; \ \ell_2 = \frac{m_1}{m_1 + m_2}\ell$$

Now let the spring be stretched to the left and right, but let the center of mass be unmoved.

$$x = x_1 + x_2 \ ; \ m_1\left(\ell_1 + x_1\right) = m_2\left(\ell_2 + x_2\right) \quad \rightarrow$$

$$m_1\ell_1 + m_1x_1 = m_2\ell_2 + m_2x_2 \quad \rightarrow \quad \boxed{m_1x_1 = m_2x_2}$$

This is the second relationship requested in the problem. Now use the differential relationships.

$$m_1\frac{d^2x_1}{dt^2} = -kx \ ; \ m_2\frac{d^2x_2}{dt^2} = -kx \quad \rightarrow \quad \frac{d^2x_1}{dt^2} = -\frac{k}{m_1}x \ ; \ \frac{d^2x_2}{dt^2} = -\frac{k}{m_2}x$$

$$\frac{d^2x_1}{dt^2} + \frac{d^2x_2}{dt^2} = -kx\left(\frac{1}{m_1} + \frac{1}{m_2}\right) \quad \rightarrow \quad \frac{d^2\left(x_1 + x_2\right)}{dt^2} = -kx\frac{m_1 + m_2}{m_1m_2} = -\frac{k}{\mu}x \quad \rightarrow \quad \mu\frac{d^2x}{dt^2} = -kx$$

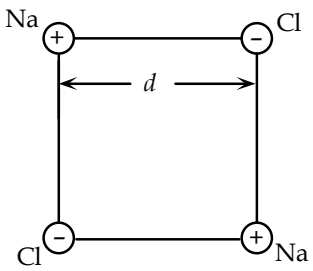
This last equation is the differential equation for simple harmonic motion, as in Eq. 14-3, with m replaced by μ. The frequency is given by Eq. 14-7a, $f = \frac{1}{2\pi}\sqrt{\frac{k}{\mu}}$, which is the same as Eq. 40-5.

20. The ionic cohesive energy is given right after Eq. 40-9, and derived in the solution to Problem 25. The Madelung constant is 1.75.

$$U_0 = -\frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r_0}\left(1-\frac{1}{m}\right) = -(1.75)\frac{\left(2.30\times10^{-28}\,\text{J•m}\right)}{\left(0.28\times10^{-9}\,\text{m}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}\left(1-\tfrac{1}{8}\right) = \boxed{-7.9\,\text{eV}}$$

21. Because each ion occupies a cell of side s, a molecule occupies two cells. Use the value of the density to solve for the desired distance.

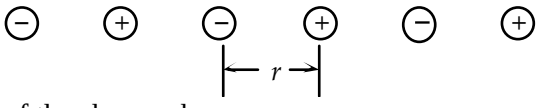
$$\rho = \frac{\text{mass}}{\text{volume}} = \frac{m_{\text{NaCl}}}{2s^3} \quad \rightarrow$$



$$s = \left(\frac{m_{\text{NaCl}}}{2\rho}\right)^{1/3} = \left[\frac{\left(58.44\,\text{u}\right)\left(1.661\times10^{-27}\,\text{kg/u}\right)}{2\left(2.165\dfrac{\text{g}}{\text{cm}^3}\right)\left(\dfrac{1\,\text{kg}}{1000\,\text{g}}\right)\left(\dfrac{10^6\,\text{cm}^3}{1\,\text{m}^3}\right)}\right]^{1/3} = \boxed{2.826\times10^{-10}\,\text{m}}$$

22. Because each ion occupies a cell of side s, a molecule occupies two cells. Use the value of the density to solve for the desired distance.

$$\rho = \frac{\text{mass}}{\text{volume}} = \frac{m_{\text{KCl}}}{2s^3} \quad \rightarrow$$



$$s = \left(\frac{m_{\text{KCl}}}{2\rho}\right)^{1/3} = \left[\frac{\left(39.10\,\text{u}+35.45\,\text{u}\right)\left(1.661\times10^{-27}\,\text{kg/u}\right)}{2\left(1.99\dfrac{\text{g}}{\text{cm}^3}\right)\left(\dfrac{1\,\text{kg}}{1000\,\text{g}}\right)\left(\dfrac{10^6\,\text{cm}^3}{1\,\text{m}^3}\right)}\right]^{1/3} = \boxed{3.15\times10^{-10}\,\text{m}}$$

23. According to Section 40-5, the NaCl crystal is face-centered cubic. It is illustrated in Figure 40-24. We consider four of the labeled ions from Figure 40-24. See the adjacent diagram. The distance from an Na ion to a Cl ion is labeled as d, and the distance from an Na ion to the nearest neighbor Na ion is called D.

$$D = d\sqrt{2} = \left(0.24\,\text{nm}\right)\sqrt{2} = \boxed{0.34\,\text{nm}}$$

24. See the diagram. Select a charge in the middle of the chain. There will be two charges of opposite sign a distance r away, two charges of the same sign a distance $2r$ away, etc. Calculate the potential energy of the chosen charge.

$$U = \frac{1}{4\pi\varepsilon_0}\left(\frac{-2e^2}{r}\right)+\frac{1}{4\pi\varepsilon_0}\left(\frac{+2e^2}{2r}\right)+\frac{1}{4\pi\varepsilon_0}\left(\frac{-2e^2}{3r}\right)+\frac{1}{4\pi\varepsilon_0}\left(\frac{+2e^2}{4r}\right)+\cdots$$

$$= -\frac{2e^2}{4\pi\varepsilon_0 r}\left(1-\tfrac{1}{2}+\tfrac{1}{3}-\tfrac{1}{4}+\cdots\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

From Appendix A, $\ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^2 - \frac{1}{4}x^4 + \cdots$. Evaluate this expansion at $x = 1$.

$$\ln(1+1) = 1 - \tfrac{1}{2} + \tfrac{1}{3} - \tfrac{1}{4} + \cdots = \ln 2 \quad \rightarrow \quad U = -\frac{2e^2}{4\pi\varepsilon_0 r}\left(1 - \tfrac{1}{2} + \tfrac{1}{3} - \tfrac{1}{4} + \cdots\right) = -\frac{2e^2}{4\pi\varepsilon_0 r}\ln 2$$

From Section 40-5, the potential energy is given as $U = -\dfrac{\alpha e^2}{4\pi\varepsilon_0 r}$. Equate the two expressions for the potential energy to evaluate the Madelung constant.

$$U = -\frac{\alpha e^2}{4\pi\varepsilon_0 r} = -\frac{2e^2}{4\pi\varepsilon_0 r}\ln 2 \quad \rightarrow \quad \boxed{\alpha = 2\ln 2}$$

25. (*a*) Start with Eq. 40-9 and find the equilibrium distance, which minimizes the potential energy. Call that equilibrium distance r_0.

$$U = -\frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r} + \frac{B}{r^m} \quad ; \quad \left.\frac{dU}{dr}\right|_{r=r_0} = \left(\frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r^2} - m\frac{B}{r^{m+1}}\right)_{r=r_0} = \frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r_0^2} - m\frac{B}{r_0^{m+1}} = 0 \quad \rightarrow$$

$$B = \frac{\alpha}{4\pi\varepsilon_0}\frac{e^2 r_0^{m-1}}{m}$$

$$U_0 = U(r = r_0) = -\frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r_0} + \frac{B}{r_0^m} = -\frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r_0} + \frac{\dfrac{\alpha}{4\pi\varepsilon_0}\dfrac{e^2 r_0^{m-1}}{m}}{r_0^m} = -\frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r_0}\left(1 - \frac{1}{m}\right)$$

(*b*) For NaI, we evaluate U_0 with $m = 10$, $\alpha = 1.75$, and $r_0 = 0.33\text{nm}$.

$$U_0 = -\frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r_0}\left(1 - \frac{1}{m}\right) = -(1.75)\frac{2.30\times10^{-28}\,\text{J•m}}{(0.33\times10^{-9}\,\text{m})(1.60\times10^{-19}\,\text{J/eV})}\left(1 - \tfrac{1}{10}\right) = -6.861\text{eV}$$

$$\approx \boxed{-6.9\,\text{eV}}$$

(*c*) For MgO, we evaluate U_0 with $m = 10$, $\alpha = 1.75$, and $r_0 = 0.21\text{nm}$.

$$U_0 = -\frac{\alpha}{4\pi\varepsilon_0}\frac{e^2}{r_0}\left(1 - \frac{1}{m}\right) = -(1.75)\frac{2.30\times10^{-28}\,\text{J•m}}{(0.21\times10^{-9}\,\text{m})(1.60\times10^{-19}\,\text{J/eV})}\left(1 - \tfrac{1}{10}\right) = -10.78\text{eV}$$

$$\approx \boxed{-11\text{eV}}$$

(*d*) Calculate the % difference using $m = 8$ instead of $m = 10$.

$$\frac{U_{0\,m=8} - U_{0\,m=10}}{U_{0\,m=10}} = \frac{-\dfrac{\alpha}{4\pi\varepsilon_0}\dfrac{e^2}{r_0}\left(1 - \tfrac{1}{8}\right) - -\dfrac{\alpha}{4\pi\varepsilon_0}\dfrac{e^2}{r_0}\left(1 - \tfrac{1}{10}\right)}{-\dfrac{\alpha}{4\pi\varepsilon_0}\dfrac{e^2}{r_0}\left(1 - \tfrac{1}{10}\right)} = \frac{\left(1 - \tfrac{1}{8}\right) - \left(1 - \tfrac{1}{10}\right)}{\left(1 - \tfrac{1}{10}\right)} = \frac{\tfrac{1}{10} - \tfrac{1}{8}}{\left(1 - \tfrac{1}{10}\right)} = -0.0278$$

$$\approx \boxed{-2.8\%}$$

26. We follow Example 40-9. The density of occupied states (number of states per unit volume in an infinitesimal energy range) is given by Eq. 40-15. Because we are using a small energy range, we estimate the calculation with a difference expression. We let *N* represent the number of states, and *V* represent the volume under consideration.

$$N \approx g(E)V\Delta E = \frac{8\sqrt{2}\pi m^{3/2}}{h^3}E^{1/2}V\Delta E$$

$$E = \tfrac{1}{2}(E_\text{F} + 0.985E_\text{F}) = 0.9925E_\text{F} \quad ; \quad \Delta E = E_\text{F} - 0.985E_\text{F} = 0.015E_\text{F} = 0.0822\,\text{eV}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$N = \frac{8\sqrt{2}\pi\left(9.11\times10^{-31}\,\text{kg}\right)^{3/2}}{\left(6.63\times10^{-34}\,\text{J•s}\right)^3}\sqrt{0.9925\left(5.48\,\text{eV}\right)}\left(1.0\times10^{-6}\,\text{m}^3\right)\left(0.0822\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)^{3/2}$$

$$= \boxed{1.3\times10^{21}\,\text{states}}$$

27. We follow Example 40-9. The density of occupied states (number of states per unit volume in an infinitesimal energy range) is given by Eq. 40-15. Because we are using a small energy range, we estimate the calculation with a difference expression. We let N represent the number of states, and V represent the volume under consideration.

$$N \approx g(E)V\Delta E = \frac{8\sqrt{2}\pi m^{3/2}}{h^3}E^{1/2}V\Delta E$$

$$= \frac{8\sqrt{2}\pi\left(9.11\times10^{-31}\,\text{kg}\right)^{3/2}}{\left(6.63\times10^{-34}\,\text{J•s}\right)^3}\sqrt{\left(7.025\,\text{eV}\right)}\left(1.0\times10^{-6}\,\text{m}^3\right)\left(0.05\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)^{3/2}$$

$$= \boxed{9.0\times10^{20}\,\text{states}}$$

28. The density of molecules in an ideal gas can be found from the ideal gas law.

$$PV = NkT \;\rightarrow\; \left(\frac{N}{V}\right)_{\text{gas}} = \frac{P}{kT} = \frac{1.013\times10^5\,\text{Pa}}{\left(1.38\times10^{-23}\,\text{J/K}\right)\left(285\,\text{K}\right)} = 2.576\times10^{25}\,\text{m}^{-3}$$

We assume that each copper atom contributes one free electron, and use the density of copper as given in Table 13-1.

$$\left(\frac{N}{V}\right)_{\text{e's}} = \left(\frac{1\text{e}}{\text{Cu atom}}\right)\left(\frac{6.02\times10^{23}\,\text{Cu atoms}}{63.546\times10^{-3}\,\text{kg}}\right)\left(\frac{8.9\times10^3\,\text{kg}}{\text{m}^3}\right) = 8.431\times10^{28}\,\text{m}^{-3}$$

$$\frac{\left(\frac{N}{V}\right)_{\text{gas}}}{\left(\frac{N}{V}\right)_{\text{e's}}} = \frac{2.576\times10^{25}\,\text{m}^{-3}}{8.431\times10^{28}\,\text{m}^{-3}} = \boxed{3.1\times10^{-4}}$$

29. We use Eq. 40-14 for the occupancy probability, and solve for the energy. The Fermi energy is 7.0 eV.

(*a*) Evaluate for T = 295 K.

$$f(E) = \frac{1}{e^{(E-E_\text{F})/kT}+1} \;\rightarrow$$

$$E = kT\ln\left[\frac{1}{f(E)}-1\right] + E_\text{F} = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)}\left(295\,\text{K}\right)\ln\left(\frac{1}{0.850}-1\right) + 7.0\,\text{eV}$$

$$= \boxed{6.96\,\text{eV}}$$

(*b*) Evaluate for T = 750 K.

$$f(E) = \frac{1}{e^{(E-E_\text{F})/kT}+1} \;\rightarrow$$

$$E = kT\ln\left[\frac{1}{f(E)}-1\right] + E_\text{F} = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)}\left(750\,\text{K}\right)\ln\left(\frac{1}{0.850}-1\right) + 7.0\,\text{eV}$$

$$= \boxed{6.89\,\text{eV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

30. We use Eq. 40-14 for the occupancy probability, and solve for the energy. The Fermi energy is 7.0 eV.

(*a*) Evaluate for T = 295 K.

$$f(E) = \frac{1}{e^{(E-E_F)/kT}+1} \rightarrow$$

$$E = kT\ln\left[\frac{1}{f(E)}-1\right] + E_F = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)}(295\,\text{K})\ln\left(\frac{1}{0.150}-1\right) + 7.0\,\text{eV}$$

$$= \boxed{7.04\,\text{eV}}$$

(*b*) Evaluate for T = 950 K.

$$f(E) = \frac{1}{e^{(E-E_F)/kT}+1} \rightarrow$$

$$E = kT\ln\left[\frac{1}{f(E)}-1\right] + E_F = \frac{\left(1.38\times10^{-23}\,\text{J/K}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)}(950\,\text{K})\ln\left(\frac{1}{0.150}-1\right) + 7.0\,\text{eV}$$

$$= \boxed{7.14\,\text{eV}}$$

31. The occupancy probability is given by Eq. 40-14. The Fermi level for copper is 7.0 eV.

$$f = \frac{1}{e^{(E-E_F)/kT}+1} = \frac{1}{e^{(1.015E_F-E_F)/kT}+1} = \frac{1}{e^{\left[0.015(7.0\,\text{eV})\left(1.60\times10^{-19}\,\text{J/eV}\right)\right]/\left[\left(1.38\times10^{-23}\,\text{J/K}\right)(295\,\text{K})\right]}+1} = 0.0159$$

$$\approx \boxed{1.6\%}$$

32. We follow Example 40-10.

(*a*) Because each zinc atom contributes two free electrons, the density of free electrons is twice the density of atoms.

$$\frac{N}{V} = \left(7100\,\text{kg/m}^3\right)\left(\frac{6.02\times10^{23}\,\text{atoms/mol}}{65.409\times10^{-3}\,\text{kg/mol}}\right)(2\,\text{free electrons/atom}) = 1.307\times10^{29}\,\text{m}^{-3}$$

$$\approx \boxed{1.3\times10^{29}\,\text{m}^{-3}}$$

(*b*) The Fermi energy is given by Eq. 40-12.

$$E_F = \frac{h^2}{8m}\left(\frac{3}{\pi}\frac{N}{V}\right)^{2/3} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)^2}{8\left(9.11\times10^{-31}\,\text{kg}\right)}\left[\frac{3}{\pi}\left(1.307\times10^{29}\,\text{m}^{-3}\right)\right]^{2/3}\left(\frac{1}{1.60\times10^{-19}\,\text{J/eV}}\right)$$

$$= 9.414\,\text{eV} \approx \boxed{9.4\,\text{eV}}$$

(*c*) The Fermi speed is the speed of electrons with the Fermi energy.

$$v_F = \sqrt{\frac{2E_F}{m}} = \sqrt{\frac{2(9.414\,\text{eV})\left(1.60\times10^{-19}\,\text{J/eV}\right)}{\left(9.11\times10^{-31}\,\text{kg}\right)}} = \boxed{1.8\times10^6\,\text{m/s}}$$

33. We follow Example 40-10. We need the number of conduction electrons per unit volume of sodium.

$$\frac{N}{V} = \left(970\,\text{kg/m}^3\right)\left(\frac{6.02\times10^{23}\,\text{atoms/mol}}{22.99\times10^{-3}\,\text{kg/mol}}\right)(1\,\text{free electrons/atom}) = 2.540\times10^{28}\,\text{m}^{-3}$$

The Fermi energy is given by Eq. 40-12.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E_F = \frac{h^2}{8m}\left(\frac{3}{\pi}\frac{N}{V}\right)^{2/3} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)^2}{8\left(9.11\times10^{-31}\,\text{kg}\right)}\left[\frac{3}{\pi}\left(2.540\times10^{28}\,\text{m}^{-3}\right)\right]^{2/3}\left(\frac{1}{1.60\times10^{-19}\,\text{J/eV}}\right) = 3.159\,\text{eV}$$

$$\approx \boxed{3.2\,\text{eV}}$$

The Fermi speed is the speed of electrons with the Fermi energy.

$$v_F = \sqrt{\frac{2E_F}{m}} = \sqrt{\frac{2\left(3.159\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}{\left(9.11\times10^{-31}\,\text{kg}\right)}} = \boxed{1.1\times10^6\,\text{m/s}}$$

34. (*a*) Find the density of free electrons from Eq. 40-12.

$$E_F = \frac{h^2}{8m}\left(\frac{3}{\pi}\frac{N}{V}\right)^{2/3} \quad \rightarrow$$

$$\frac{N}{V} = \frac{\pi}{3}\left(\frac{8mE_F}{h^2}\right)^{3/2} = \frac{\pi}{3}\left[\frac{8\left(9.11\times10^{-31}\,\text{kg}\right)\left(11.63\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}{\left(6.63\times10^{-34}\,\text{J•s}\right)^2}\right]^{3/2}$$

$$= 1.7945\times10^{29}\,\text{m}^{-3} \approx \boxed{1.79\times10^{29}\,\text{m}^{-3}}$$

(*b*) Let *n* represent the valence number, so there are *n* free electrons per atom.

$$\frac{N}{V} = \left(270\,\text{kg/m}^3\right)\left(\frac{6.02\times10^{23}\,\text{atoms/mol}}{27.0\times10^{-3}\,\text{kg/mol}}\right)\left(n\,\text{free electrons/atom}\right) \quad \rightarrow$$

$$n = \left(\frac{27.0\times10^{-3}\,\text{kg/mol}}{6.02\times10^{23}\,\text{atoms/mol}}\right)\left(\frac{1}{270\,\text{kg/m}^3}\right)\left(1.7945\times10^{29}\,\text{m}^{-3}\right) = 2.981 \approx \boxed{3}$$

This agrees nicely with aluminum's position in the periodic table, and its electron configuration of $1s^2 2s^2 2p^6 3s^2 3p^1$. The level 3 electrons are the valence electrons.

35. We calculate the given expression, with $T = 0$, so that the maximum energy is E_F. The value of $f(E)$ at $T = 0$ is given below Eq. 40-14.

$$\overline{E} = \frac{\int_0^{E_F} E n_0(E)\,dE}{\int_0^{E_F} n_0(E)\,dE} = \frac{\int_0^{E_F} E g(E) f(E)\,dE}{\int_0^{E_F} g(E) f(E)\,dE} = \frac{\int_0^{E_F} E\left(\frac{8\sqrt{2}\pi m^{3/2}}{h^3}E^{1/2}\right)(1)\,dE}{\int_0^{E_F}\left(\frac{8\sqrt{2}\pi m^{3/2}}{h^3}E^{1/2}\right)(1)\,dE} = \frac{\int_0^{E_F} E^{3/2}\,dE}{\int_0^{E_F} E^{1/2}\,dE}$$

$$= \frac{\frac{2}{5}E_F^{5/2}}{\frac{2}{3}E_F^{3/2}} = \frac{3}{5}E_F$$

36. We first find the density of neutrons, and then use Eq. 40-12.

$$\frac{N}{V} = \left(\frac{1\text{ neutron}}{1.675\times10^{-27}\,\text{kg}}\right)\left[2.5\left(1.99\times10^{30}\,\text{kg}\right)\right]\left[\frac{1}{\frac{4}{3}\pi\left(12{,}000\,\text{m}\right)^3}\right] = 4.103\times10^{44}\,\text{m}^{-3}$$

$$E_F = \frac{h^2}{8m}\left(\frac{3}{\pi}\frac{N}{V}\right)^{2/3} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)^2}{8\left(1.675\times10^{-27}\,\text{kg}\right)}\left[\frac{3}{\pi}\left(4.103\times10^{44}\,\text{m}^{-3}\right)\right]^{2/3}\left(\frac{1}{1.60\times10^{-13}\,\text{J/MeV}}\right)$$

$$= 109.8\,\text{MeV} \approx \boxed{110\,\text{MeV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

37. We start with Eq. 38-13 for the energy level as a function of *n*. If we solve for *n*, we have the number of levels with energies between 0 and *E*. Taking the differential of that expression will give the number of levels with energies between E and dE. Finally, we multiply by 2 since there can be 2 electrons (with opposite spins) in each energy level.

$$E = n^2 \frac{h^2}{8m\ell^2} \quad \rightarrow \quad n = \sqrt{\frac{8m\ell^2}{h^2}}\sqrt{E} \quad \rightarrow \quad dn = \sqrt{\frac{8m\ell^2}{h^2}}\,\tfrac{1}{2}\frac{dE}{\sqrt{E}} \quad \rightarrow$$

$$g_\ell = 2\frac{dn}{dE} = 2\frac{\sqrt{\frac{8m\ell^2}{h^2}}\,\frac{1}{2}\frac{dE}{\sqrt{E}}}{dE} = \boxed{\sqrt{\frac{8m\ell^2}{h^2 E}}}$$

38. We use Eq. 40-14, with $E = E_\text{F}$.

$$f = \frac{1}{e^{(E-E_\text{F})/kT}+1} = \frac{1}{e^0+1} = \frac{1}{1+1} = \frac{1}{2}$$

The result is independent of the value of *T*.

39. (*a*) Eq. 38-13 gives the energy levels as a function of *n*, the number of levels. Since there are 2 electrons in every energy level, $n = N/2$. The Fermi energy will be the highest energy level occupied with *N* electrons.

$$E_n = n^2 \frac{h^2}{8m\ell^2} = \left(\tfrac{1}{2}N\right)^2 \frac{h^2}{8m\ell^2} = \frac{h^2N^2}{32m\ell^2} \quad \rightarrow \quad \boxed{E_\text{F} = \frac{h^2N^2}{32m\ell^2}}$$

(*b*) The smallest amount of energy that this metal can absorb is the spacing between energy levels.

$$\Delta E = E_{n+1} - E_n = \frac{h^2}{8m\ell^2}\left[(n+1)^2 - n^2\right] = \frac{h^2}{8m\ell^2}(2n+1) = \boxed{\frac{h^2}{8m\ell^2}(N+1)}$$

(*c*) We calculate the limit requested.

$$\frac{\Delta E}{E_\text{F}} = \frac{\frac{h^2}{8m\ell^2}(N+1)}{\frac{h^2N^2}{32m\ell^2}} = \boxed{\frac{4}{N}}$$

For large *N*, this is a very small change in energy. Thus a very small change in energy will allow an electron to change energy levels, and so the metal conducts very easily.

40. (*a*) We use Eq. 40-14, with the data as given in the problem.

$$\frac{E-E_\text{F}}{kT} = \frac{(0.12\,\text{eV})(1.60\times10^{-19}\,\text{J/eV})}{k(1.38\times10^{-23}\,\text{J/K})(293\,\text{K})} = 4.74848$$

$$f = \frac{1}{e^{(E-E_\text{F})/kT}+1} = \frac{1}{e^{4.74848}+1} = \frac{1}{116.409} = 8.590\times10^{-3} \approx \boxed{8.6\times10^{-3}}$$

This is reasonable. Very few states this far above the Fermi energy are occupied at this relatively low temperature.

(*b*) Use a similar calculation to part (*a*).

$$\frac{E-E_\text{F}}{kT} = \frac{(-0.12\,\text{eV})(1.60\times10^{-19}\,\text{J/eV})}{k(1.38\times10^{-23}\,\text{J/K})(293\,\text{K})} = -4.74848$$

$$f = \frac{1}{e^{(E-E_\text{F})/kT}+1} = \frac{1}{e^{-4.74848}+1} = \frac{1}{1.008665} = 0.991409 \approx \boxed{0.99}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) Since the probability that the state is occupied is 0.991409, the probability that the state is unoccupied is $1-0.991409=8.591\times10^{-3}\approx\boxed{8.6\times10^{-3}}$. This is the same as part (*a*).

41. We consider the cube to be a three-dimensional infinite well, with a width of ℓ in each dimension. We apply the boundary conditions as in Section 38-8 separately to each dimension. Each dimension gives a quantum number which we label as n_1, n_2, and n_3. We then have a contribution to the energy of the bound particle from each quantum number, as in Eq. 38-13.

$$E=E_1+E_2+E_3=n_1^2\frac{h^2}{8m\ell^2}+n_2^2\frac{h^2}{8m\ell^2}+n_3^2\frac{h^2}{8m\ell^2}=\frac{h^2}{8m\ell^2}\left(n_1^2+n_2^2+n_3^2\right),\ n_1,n_2,n_3=1,2,3,\cdots$$

Specifying the three quantum numbers gives a state and the corresponding energy.

Choosing axes as specified in the problem, the equation of a sphere of radius *R* in that coordinate system is $R^2=n_1^2+n_2^2+n_3^2$. Each state "contained" in that sphere could be indicated by a cube of side length 1, and each state can have two electrons (two spin states). The "volume" of that sphere is $\frac{1}{8}$ of a full sphere. From that we calculate the number of states in one octant, and then $g(E)$.

$$N=2\left(\tfrac{1}{8}\right)\tfrac{4}{3}\pi R^3=\frac{\pi}{3}\left(n_1^2+n_2^2+n_3^2\right)^{3/2}=\frac{\pi}{3}\left(\frac{8m\ell^2}{h^2}E\right)^{3/2}$$

$$g(E)=\frac{1}{V}\frac{dN}{dE}=\frac{1}{\ell^3}\frac{\pi}{3}\left(\frac{8m\ell^2}{h^2}\right)^{3/2}\frac{3}{2}E^{1/2}=\frac{\pi}{2}\left(\frac{8m}{h^2}\right)^{3/2}E^{1/2}=\boxed{\frac{8\sqrt{2}\pi m^{3/2}}{h^3}E^{1/2}}$$

42. The photon with the minimum frequency for conduction must have an energy equal to the energy gap.

$$E_g=hf=\frac{hc}{\lambda}=\frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\left(580\times10^{-9}\,\text{m}\right)}=\boxed{2.14\,\text{eV}}$$

43. The photon with the longest wavelength or minimum frequency for conduction must have an energy equal to the energy gap:

$$\lambda=\frac{c}{f}=\frac{hc}{hf}=\frac{hc}{E_g}=\frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\left(1.14\,\text{eV}\right)}=1.09\times10^{-6}\,\text{m}=\boxed{1.09\,\mu\text{m.}}$$

44. The energy of the photon must be greater than or equal to the energy gap. Thus the longest wavelength that will excite an electron is

$$\lambda=\frac{c}{f}=\frac{hc}{hf}=\frac{hc}{E_g}=\frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\left(0.72\,\text{eV}\right)}=1.7\times10^{-6}\,\text{m}=1.7\,\mu\text{m}$$

Thus the wavelength range is $\boxed{\lambda\le1.7\,\mu\text{m}}$.

45. (*a*) In the 2*s* shell of an atom, $\ell=0$, so there are two states: $m_s=\pm\frac{1}{2}$. When *N* atoms form bands, each atom provides 2 states, so the total number of states in the band is $\boxed{2N.}$

(*b*) In the 2*p* shell of an atom, $\ell=1$, so there are three states from the m_ℓ values: $m_\ell=0,\pm1$; each of which has two states from the m_s values: $m_s=\pm\frac{1}{2}$, for a total of 6 states. When *N* atoms form bands, each atom provides 6 states, so the total number of states in the band is $\boxed{6N.}$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) In the 3*p* shell of an atom, $\ell = 1$, so there are three states from the m_ℓ values: $m_\ell = 0, \pm 1$; each of which has two states from the m_s values: $m_s = \pm\frac{1}{2}$, for a total of 6 states. When *N* atoms form bands, each atom provides 6 states, so the total number of states in the band is $\boxed{6N.}$

(*d*) In general, for a value of ℓ, there are $2\ell + 1$ states from the m_ℓ values: $m_\ell = 0, \pm 1, \ldots, \pm\ell$. For each of these there are two states from the m_s values: $m_s = \pm\frac{1}{2}$, for a total of $2(2\ell + 1)$ states. When *N* atoms form bands, each atom provides $2(2\ell + 1)$ states, so the total number of states in the band is $\boxed{2N(2\ell + 1).}$

46. The minimum energy provided to an electron must be equal to the energy gap. Divide the total available energy by the energy gap to estimate the maximum number of electrons that can be made to jump.

$$N = \frac{hf}{E_g} = \frac{(760 \times 10^3 \text{ eV})}{(0.72 \text{ eV})} = \boxed{1.1 \times 10^6}$$

47. Calculate the number of conduction electrons in a mole of pure silicon. Also calculate the additional conduction electrons provided by the doping, and then take the ratio of those two numbers of conduction electrons.

$$N_{\text{Si}} = \left[\frac{(28.09 \times 10^{-3} \text{ kg/mol})}{(2330 \text{ kg/m}^3)}\right](10^{16} \text{ electrons/m}^3) = 1.206 \times 10^{11} \text{ electrons/mole}$$

$$N_{\text{doping}} = \frac{(6.02 \times 10^{23} \text{ atoms})}{1.2 \times 10^6} = 5.017 \times 10^{17} \text{ added conduction electrons.}$$

$$\frac{N_{\text{doping}}}{N_{\text{Si}}} = \frac{(5.017 \times 10^{17})}{(1.206 \times 10^{11})} = 4.16 \times 10^6 \approx \boxed{4 \times 10^6}$$

48. The wavelength is found from the energy gap.

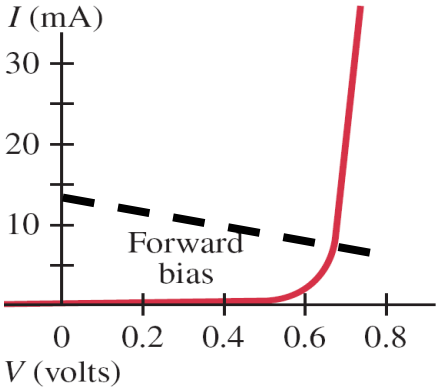
$$\lambda = \frac{c}{f} = \frac{hc}{hf} = \frac{hc}{E_g} = \frac{(6.63 \times 10^{-34} \text{ J•s})(3.00 \times 10^8 \text{ m/s})}{(1.60 \times 10^{-19} \text{ J/eV})(1.6 \text{ eV})} = 7.8 \times 10^{-7} \text{ m} = \boxed{0.78\,\mu\text{m}}$$

49. The photon will have an energy equal to the energy gap:

$$E_g = hf = \frac{hc}{\lambda} = \frac{(6.63 \times 10^{-34} \text{ J•s})(3.00 \times 10^8 \text{ m/s})}{(1.60 \times 10^{-19} \text{ J/eV})(680 \times 10^{-9} \text{ m})} = \boxed{1.8 \text{ eV}}$$

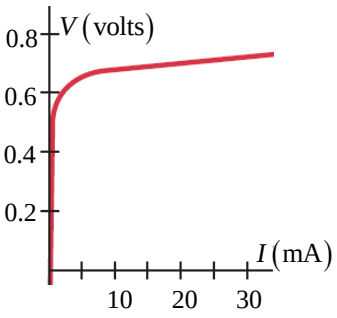
50. From the current-voltage characteristic graph in Figure 40-38, we see that a current of 12 mA means a voltage of about 0.68 V across the diode. The battery voltage is the sum of the voltages across the diode and the resistor.

$$V_{\text{battery}} = V_{\text{diode}} + V_{\text{R}} = 0.68 \text{ V} + (0.012 \text{ A})(860 \Omega) = \boxed{11 \text{ V}}$$

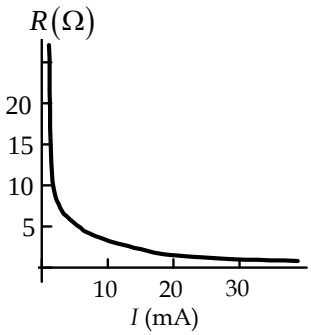


© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

51. The battery voltage is the sum of the voltages across the diode and the resistor.



$$V_{\text{battery}} = V_{\text{diode}} + V_R;$$



$$2.0\,\text{V} = V_{\text{diode}} + I(150\,\Omega) \quad \rightarrow \quad I = -\frac{V_{\text{diode}}}{150\,\Omega} + \frac{2.0\,\text{V}}{150\,\Omega}$$

This is the equation for a straight line which passes through the points (0 V, 13.3 mA) and (0.8 V, 8 mA). The line has a *y*-intercept of 13.3 mA and a slope of 6.67 mA/V. If we assume the operating voltage of the diode is about 0.7 V, then the current is about $\boxed{8.6\text{ mA}}$. There is some approximation involved in the answer.

52. We have copied the graph for $V > 0$ and rotated it so that it shows V as a function of I. This is the first diagram below. The resistance is the slope of that first graph. The slope, and thus the resistance, is very high for low currents, and decreases for larger currents, approaching 0. As an approximate value, we see that the voltage changes from about 0.55 V to 0.65 V as the current goes from 0 to 10 mA. That makes the resistance about 10 ohms when the current is about 5 mA. The second diagram is a sketch of the resistance.

53. (*a*) For a half-wave rectifier without a capacitor, the current is zero for half the time. We approximate the average current as half of the full rms current.

$$I_{\text{av}} = \tfrac{1}{2}\frac{V_{\text{rms}}}{R} = \tfrac{1}{2}\frac{(120\,\text{V})}{(35\,\text{k}\Omega)} = \boxed{1.7\,\text{mA}}$$

(*b*) For a full-wave rectifier without a capacitor, the current is positive all the time. We approximate the average current as equal to the full rms current.

$$I_{\text{av}} = \frac{V_{\text{rms}}}{R} = \frac{(120\,\text{V})}{(35\,\text{k}\Omega)} = \boxed{3.4\,\text{mA}}$$

54. The band gap is the energy corresponding to the emitted wavelength.

$$E = \frac{hc}{\lambda} = \frac{(6.63\times10^{-34}\,\text{J}\cdot\text{s})(3.00\times10^{8}\,\text{m/s})}{(1.3\times10^{-6}\,\text{m})(1.60\times10^{-19}\,\text{J/eV})} = \boxed{0.96\,\text{eV}}$$

55. There will be a current in the resistor while the ac voltage varies from 0.6 V to 9.0 V rms. Because the 0.6 V is small, the voltage across the resistor will be almost sinusoidal, so the rms voltage across the resistor will be close to $9.0\,\text{V} - 0.6\,\text{V} = 8.4\,\text{V}$.

(*a*) For a half-wave rectifier without a capacitor, the current is zero for half the time. We ignore the short time it takes for the voltage to increase from 0 to 0.6 V, and so current is flowing in

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

the resistor for about half the time. We approximate the average current as half of the full rms current.

$$I_{\text{av}} = \tfrac{1}{2}\frac{V_{\text{rms}}}{R} = \tfrac{1}{2}\frac{8.4\,\text{V}}{0.120\,\text{k}\Omega} = \boxed{35\,\text{mA}}$$

(*b*) For a full-wave rectifier without a capacitor, the current is positive all the time. We ignore the short times it takes for the voltage to increase from 0 to 0.6 V, and so current is flowing in the resistor all the time. We approximate the average current as the full rms current.

$$I_{\text{av}} = \frac{V_{\text{rms}}}{R} = \frac{8.4\,\text{V}}{0.120\,\text{k}\Omega} = \boxed{70\,\text{mA}}$$

56. (*a*) The time constant for the circuit is $\tau_1 = RC_1 = \left(28\times10^3\,\Omega\right)\left(35\times10^{-6}\,\text{F}\right) = 0.98\,\text{s}$. As seen in Figure 40-40(c), there are two peaks per cycle. The period of the rectified voltage is $T = \frac{1}{120}\,\text{s} = 0.0083\,\text{s}$. Because $\tau_1 \gg T$, the voltage across the capacitor will be essentially constant during a cycle, so the average voltage is the same as the peak voltage. The average current is basically constant.

$$I_{\text{avg}} = \frac{V_{\text{avg}}}{R} = \frac{V_{\text{peak}}}{R} = \frac{\sqrt{2}V_{\text{rms}}}{R} = \frac{\sqrt{2}\left(120\,\text{V}\right)}{\left(28\times10^3\,\Omega\right)} = \boxed{6.1\,\text{mA}}$$

(*b*) With a different capacitor, the time constant for the circuit changes.

$$\tau_2 = RC_2 = \left(28\times10^3\,\Omega\right)\left(0.10\times10^{-6}\,\text{F}\right) = 0.0028\,\text{s}$$

Now the period of the rectified voltage is about 3 time constants, and so the voltage will decrease to about 5% $\left(e^{-3}\right)$ of the peak value during each half-cycle. We approximate the voltage as dropping linearly from its peak value to 0 over each half-cycle, and so take the average voltage as half the peak voltage.

$$I_{\text{avg}} = \frac{V_{\text{avg}}}{R} = \tfrac{1}{2}\frac{\sqrt{2}V_{\text{rms}}}{R} = \tfrac{1}{2}\frac{\sqrt{2}\left(120\,\text{V}\right)}{\left(28\times10^3\,\Omega\right)} = \boxed{3.0\,\text{mA}}$$

57. By Ohm's law, the output (collector) current times the output resistor will be the output voltage.

$$V_{\text{out}} = i_{\text{C}}R_{\text{C}} \quad\rightarrow\quad R_{\text{C}} = \frac{V_{\text{out}}}{i_{\text{C}}} = \frac{V_{\text{out}}}{\beta i_{\text{B}}} = \frac{0.35\,\text{V}}{95\left(1.0\times10^{-6}\,\text{A}\right)} = 3684\,\Omega \approx \boxed{3700\,\Omega}$$

58. By Ohm's law, the output (collector) current times the output resistor will be the output voltage.

$$V_{\text{out}} = i_{\text{C}}R_{\text{C}} = \beta i_{\text{B}}R_{\text{C}} = \left(85\right)\left(2.0\times10^{-6}\,\text{A}\right)\left(4300\,\Omega\right) = \boxed{0.73\,\text{V}}$$

59. By Ohm's law, the output (collector) current times the output resistor will be the output voltage.

$$V_{\text{out}} = i_{\text{C}}R \quad\rightarrow\quad i_{\text{C}} = \frac{V_{\text{out}}}{R} = \frac{\beta_V V_{\text{input}}}{R} = \frac{65\left(0.080\,\text{V}\right)}{25{,}000\,\Omega} = 2.08\times10^{-4}\,\text{A} \approx \boxed{0.21\,\text{mA}}$$

60. (*a*) The voltage gain is the collector ac voltage divided by the base ac voltage.

$$\beta_V = \frac{V_{\text{C}}}{V_{\text{B}}} = \frac{i_{\text{C}}R_{\text{C}}}{i_{\text{B}}R_{\text{B}}} = \beta_I\frac{R_{\text{C}}}{R_{\text{B}}} = 75\left(\frac{7.8\,\text{k}\Omega}{3.8\,\text{k}\Omega}\right) = 153.9 \approx \boxed{150}$$

(*b*) The power amplification is the output power divided by the input power.

$$\beta_{\text{P}} = \frac{i_{\text{C}}V_{\text{C}}}{i_{\text{B}}V_{\text{B}}} = \beta_I\beta_V = \left(75\right)\left(153.9\right) = 11{,}543 \approx \boxed{12{,}000}$$

61. The arrow at the emitter terminal, E, indicates the direction of current I_E. The current into the transistor must equal the current out of the transistor.

$$\boxed{I_B + I_C = I_E}$$

62. For an electron confined in 1 dimension, we find the uncertainty in the momentum from Eq. 38-1, $\Delta p \approx \frac{\hbar}{\Delta x}$. The momentum of the electron must be at least as big as the uncertainty in the momentum, so we approximate $p \approx \frac{\hbar}{\Delta x}$. Finally, we calculate the kinetic energy by $K = \frac{p^2}{2m}$. Find the difference in the two kinetic energies based on the two position uncertainties.

$$K = \frac{p^2}{2m} = \frac{\hbar^2}{2m(\Delta x)^2}$$

$$\Delta K = K_{\text{in atoms}} - K_{\text{molecule}} = \frac{\hbar^2}{2m}\left[\frac{1}{(\Delta x)^2_{\text{in atoms}}} - \frac{1}{(\Delta x)^2_{\text{molecule}}}\right]$$

$$= \frac{(1.055\times10^{-34}\,\text{J•s})^2}{2(9.11\times10^{-31}\,\text{kg})}\left[\frac{1}{(0.053\times10^{-9}\,\text{m})^2_{\text{in atoms}}} - \frac{1}{(0.074\times10^{-9}\,\text{m})^2_{\text{molecule}}}\right]\left(\frac{1}{1.60\times10^{-19}\,\text{J/eV}}\right)$$

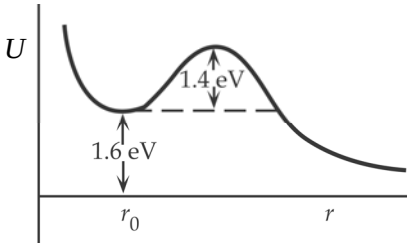
$$= 6.62\,\text{eV}$$

There are two electrons, and each one has this kinetic energy difference, so the total kinetic energy difference is $2(6.62\,\text{eV}) = 13.2\,\text{eV} \approx \boxed{13\,\text{eV}}$.

63. We find the temperature from the given relationship.

(*a*) $K = \frac{3}{2}kT \rightarrow T = \frac{2K}{3k} = \frac{2(4.0\,\text{eV})(1.60\times10^{-19}\,\text{J/eV})}{3(1.38\times10^{-23}\,\text{J/K})} = \boxed{3.1\times10^4\,\text{K}}$

(*b*) $K = \frac{3}{2}kT \rightarrow T = \frac{2K}{3k} = \frac{2(0.12\,\text{eV})(1.60\times10^{-19}\,\text{J/eV})}{3(1.38\times10^{-23}\,\text{J/K})} = \boxed{930\,\text{K}}$



64. (*a*) The potential energy for the point charges is found as from Eq. 23-10.

$$U = -\frac{1}{4\pi\varepsilon_0}\frac{e^2}{r} = -\frac{(2.30\times10^{-28}\,\text{J•m})}{(0.27\times10^{-9}\,\text{m})(1.60\times10^{-19}\,\text{J/eV})} = -5.32\,\text{eV} \approx \boxed{-5.3\,\text{eV}}$$

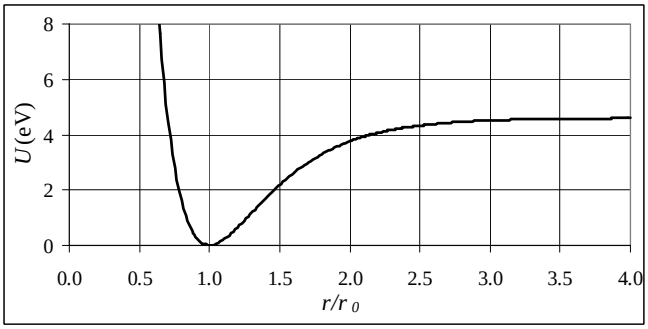
(*b*) Because the potential energy of the ions is negative, 5.32 eV is released when the ions are brought together. The other energies quoted involve the transfer of the electron from the K atom to the F atom. 3.41 eV is released and 4.34 eV is absorbed in the individual electron transfer processes. Thus the total binding energy is as follows.

$$\text{Binding energy} = 5.32\,\text{eV} + 3.41\,\text{eV} - 4.34\,\text{eV} = 4.39\,\text{eV} \approx \boxed{4.4\,\text{eV}}$$

65. The diagram here is similar to Figure 40-9 and Figure 40-11. The activation energy is the energy needed to get the (initially) stable system over the barrier in the potential energy. The activation energy is 1.4 eV for this molecule. The dissociation energy is the energy that is released when the bond is broken. The dissociation energy is 1.6 eV for this molecule.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

66. (*a*) The equilibrium position is the location where the potential energy is a minimum. We find that location by setting the derivative of the potential energy equal to 0.



$$U = U_0\left[1-e^{-a(r-r_0)}\right]^2 \;;\; \frac{dU}{dr} = 2U_0\left[1-e^{-a(r-r_0)}\right]\left(ae^{-a(r-r_0)}\right) = 0 \;\rightarrow\; 1-e^{-a(r-r_0)} = 0$$

$$e^{-a(r-r_0)} = 1 \;\rightarrow\; a(r-r_0) = 0 \;\rightarrow\; \boxed{r = r_0}$$

The dissociation energy is the energy difference between the two states of equilibrium separation and infinite separation.

$$\Delta U = U_{r=\infty} - U_{r=r_0} = U_0\left[1-e^{-a(\infty-r_0)}\right]^2 - U_0\left[1-e^{-a(r_0-r_0)}\right]^2 = U_0[1-0]^2 - U_0[1-1]^2 = \boxed{U_0}$$

(*b*) See the included graph. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH40.XLS," on tab "Problem 40.66b."

67. (*a*) The reduced mass is defined in Eq. 40-4.

$$\mu = \frac{m_{\mathrm{H}}m_{\mathrm{Cl}}}{m_{\mathrm{H}}+m_{\mathrm{Cl}}} = \frac{(1.008\,\mathrm{u})(35.453\,\mathrm{u})}{(1.008\,\mathrm{u})+(35.453\,\mathrm{u})} = \boxed{0.9801\,\mathrm{u}}$$

(*b*) We find the effective spring constant from Eq. 40-5.

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{\mu}} \;\rightarrow$$

$$k = 4\pi f^2\mu = 4\pi^2\left(8.66\times10^{13}\,\mathrm{Hz}\right)^2(0.9801\,\mathrm{u})\left(1.6605\times10^{-27}\,\mathrm{kg/u}\right) = \boxed{482\,\mathrm{N/m}}$$

The spring constant for H_2 is estimated in Example 40-6 as 550 N/m.

$$\frac{k_{\mathrm{CO}}}{k_{\mathrm{H}_2}} = \frac{482\,\mathrm{N/m}}{550\,\mathrm{N/m}} = \boxed{0.88}$$

68. Vibrational states have a constant energy difference of $\Delta E_{\mathrm{vib}} = 0.54\,\mathrm{eV}$, as found in Example 40-7.

Rotational states have a varying energy difference, depending on the ℓ value, of $\Delta E_{\mathrm{rot}} = \dfrac{\hbar^2\ell}{I}$, where ℓ represents the upper energy state, as given in Eq. 40-3.

$$\Delta E_{\mathrm{rot}} = \frac{\hbar^2\ell}{I} = \frac{\hbar^2\ell}{\mu r_0^2} = \ell\,\frac{\left(1.055\times10^{-34}\,\mathrm{J\cdot s}\right)^2}{(0.5)(1.008\,\mathrm{u})\left(1.66\times10^{-27}\,\mathrm{kg/u}\right)\left(0.074\times10^{-9}\,\mathrm{m}\right)^2\left(1.60\times10^{-19}\,\mathrm{J/eV}\right)}$$

$$= (0.0152\,\mathrm{eV})\ell$$

Each gap, as represented in Figure 40-17, is larger. We add those gaps until we reach $0.54\,\mathrm{eV}$.

$\ell = 1 \rightarrow \ell = 0$: $\Delta E_{\mathrm{rot}} = 0.0152\,\mathrm{eV}$ $\quad \sum \Delta E_{\mathrm{rot}} = 0.0152\,\mathrm{eV}$

$\ell = 2 \rightarrow \ell = 1$: $\Delta E_{\mathrm{rot}} = 2(0.0152\,\mathrm{eV})$ $\quad \sum \Delta E_{\mathrm{rot}} = 3(0.0152\,\mathrm{eV}) = 0.0456\,\mathrm{eV}$

$\ell = 3 \rightarrow \ell = 2$: $\Delta E_{\mathrm{rot}} = 3(0.0152\,\mathrm{eV})$ $\quad \sum \Delta E_{\mathrm{rot}} = 6(0.0152\,\mathrm{eV}) = 0.0912\,\mathrm{eV}$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\ell = 4 \rightarrow \ell = 3:\ \Delta E_{\text{rot}} = 4(0.0152\,\text{eV}) \quad \sum \Delta E_{\text{rot}} = 10(0.0152\,\text{eV}) = 0.152\,\text{eV}$$
$$\ell = 5 \rightarrow \ell = 4:\ \Delta E_{\text{rot}} = 5(0.0152\,\text{eV}) \quad \sum \Delta E_{\text{rot}} = 15(0.0152\,\text{eV}) = 0.228\,\text{eV}$$
$$\ell = 6 \rightarrow \ell = 5:\ \Delta E_{\text{rot}} = 6(0.0152\,\text{eV}) \quad \sum \Delta E_{\text{rot}} = 21(0.0152\,\text{eV}) = 0.3192\,\text{eV}$$
$$\ell = 7 \rightarrow \ell = 8:\ \Delta E_{\text{rot}} = 7(0.0152\,\text{eV}) \quad \sum \Delta E_{\text{rot}} = 28(0.0152\,\text{eV}) = 0.4256\,\text{eV}$$
$$\ell = 8 \rightarrow \ell = 7:\ \Delta E_{\text{rot}} = 8(0.0152\,\text{eV}) \quad \sum \Delta E_{\text{rot}} = 36(0.0152\,\text{eV}) = 0.5472\,\text{eV}$$

So we see that rotational states from $\ell = 0$ to $\ell = 7$ can be "between" vibrational states, or a total of 8 rotational states.

69. The Boltzmann indicates that the population of a state decreases as the energy of the state increases, according to $N_n \propto e^{-E_n/kT}$. The rotation energy of states increases with higher ℓ values, according to Eq. 40-2. Thus states with higher values of ℓ have higher energies, and so there are fewer molecules in those states. Since the higher states are less likely to be populated, they are less likely to absorb a photon. As an example, the probability of absorption between $\ell = 1$ and $\ell = 2$ is more likely than between $\ell = 2$ and $\ell = 3$, and so the peak representing the transition between $\ell = 1$ and $\ell = 2$ is higher than the peak representing the transition between $\ell = 2$ and $\ell = 3$.

The molecule is not rigid, and so the distance between the two ions is not constant. The moment of inertia depends on the bond length, and the energy levels depend on the moment of inertia. Thus the energy levels are not exactly equally spaced.

70. From Figure 40-17, a rotational absorption spectrum would show peaks at energies of $\hbar^2/I$, $2\hbar^2/I$, $3\hbar^2/I$, etc. Adjacent peaks are separated by an energy of $\hbar^2/I$. We use the photon frequency at that energy to determine the rotational inertia.

$$\Delta E = \frac{\hbar^2}{I} \rightarrow I = \frac{\hbar^2}{\Delta E} = \frac{\hbar^2}{hf} = \frac{h}{4\pi^2 f} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{4\pi^2\left(8.4\times10^{11}\,\text{Hz}\right)} = \boxed{2.0\times10^{-47}\,\text{kg•m}^2}$$

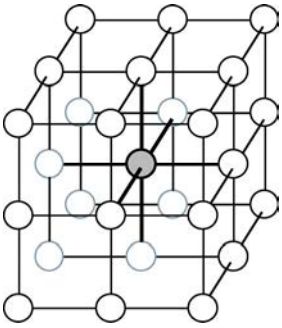
71. To use silicon to filter the wavelengths, wavelengths below the IR should cause the electron to be raised to the conduction band, so the photon is absorbed in the silicon. Let us find the shortest wavelength that will cause the electron to jump.

$$\lambda = \frac{c}{f} = \frac{hc}{hf} > \frac{hc}{E_g} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\left(1.14\,\text{eV}\right)} = 1.09\times10^{-6}\,\text{m} = \boxed{1.09\,\mu\text{m}}$$

Because this is in the IR region of the spectrum, the shorter wavelengths of visible light will excite the electron and the photon would be absorbed. So silicon could be used as a window.

72. The kinetic energy of the baton is $\frac{1}{2}I\omega^2$, and the quantum number can be found from Eq. 40-2. Let the length of the baton be *d*. We assume the quantum number will be very large.

$$\tfrac{1}{2}I\omega^2 = \frac{\ell(\ell+1)\hbar^2}{2I} \approx \frac{\ell^2\hbar^2}{2I} \rightarrow$$
$$\ell = \frac{I\omega}{\hbar} = \left[2m_{\text{end}}\left(\tfrac{1}{2}d\right)^2 + \tfrac{1}{12}m_{\text{bar}}d^2\right]\frac{2\pi f}{\hbar} =$$
$$= \left[2\left(0.38\,\text{kg}\right)\left(0.16\,\text{m}\right)^2 + \tfrac{1}{12}\left(0.26\,\text{kg}\right)\left(0.32\,\text{m}\right)^2\right]\frac{2\pi\left(1.6\,\text{s}^{-1}\right)}{\left(1.055\times10^{-34}\,\text{J•s}\right)} = 2.07\times10^{33}$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The spacing between rotational energy levels is given by Eq. 40-3. We compare that value to the rotational kinetic energy.

$$\frac{\Delta E}{E} = \frac{\frac{\ell\hbar^2}{I}}{\frac{\ell^2\hbar^2}{2I}} = \frac{1}{2\ell} = \frac{1}{2\left(2.07\times10^{33}\right)} = 2.4\times10^{-34}$$

This is such a small difference that it would not be detectable, so no, we do not need to consider quantum effects.

73. From the diagram of the cubic lattice, we see that an atom inside the cube is bonded to the six nearest neighbors. Because each bond is shared by two atoms, the number of bonds per atom is 3 (as long as the sample is large enough that most atoms are in the interior, and not on the boundary surface). We find the heat of fusion from the energy required to break the bonds:

$$\begin{aligned} L_{\text{fusion}} &= \left(\frac{\text{number of bonds}}{\text{atom}}\right)\left(\frac{\text{number of atoms}}{\text{mol}}\right)E_{\text{bond}} \\ &= (3)\left(6.02\times10^{23}\,\text{atoms/mol}\right)\left(3.9\times10^{-3}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right) \\ &= 1127\,\text{J/mol} \approx \boxed{1100\,\text{J/mol}} \end{aligned}$$

74. The longest wavelength will be the photon with the minimum energy.

$$\Delta E_{\min} = \frac{hc}{\lambda_{\max}} \quad \rightarrow \quad \lambda_{\max} = \frac{hc}{\Delta E_{\min}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(3.6\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 3.5\times10^{-7}\,\text{m}$$

So the photon must have $\boxed{\lambda \le 3.5\times10^{-7}\,\text{m}}$.

75. The photon with the minimum frequency for conduction must have an energy equal to the energy gap.

$$E_g = hf = \frac{hc}{\lambda} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.60\times10^{-19}\,\text{J/eV}\right)\left(226\times10^{-9}\,\text{m}\right)} = \boxed{5.50\,\text{eV}}$$

76. (*a*) We calculate the Fermi temperature, for a Fermi energy of 7.0 eV.

$$T_{\text{F}} = \frac{E_{\text{F}}}{k} = \frac{\left(7.0\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}{1.38\times10^{-23}\,\text{J/K}} = \boxed{8.1\times10^{4}\,\text{K}}$$

(b) We are given that $T \gg T_{\text{F}}$, and we assume that $e^{E/kT} >> 1$.

$$f(E) = \frac{1}{e^{(E-E_{\text{F}})/kT}+1} = \frac{1}{e^{\left(\frac{E}{kT}-\frac{kT_{\text{F}}}{kT}\right)}+1} \approx \frac{1}{e^{\left(\frac{E}{kT}\right)}+1} \approx \frac{1}{e^{\left(\frac{E}{kT}\right)}} = e^{-E/kT}$$

This is not useful for conductors like copper, because the Fermi temperature is higher than the melting point, and we would no longer have a solid conductor.

77. We use Eq. 40-11 with the limits given in order to determine the number of states.

$$N = V\int_{E_1}^{E_2} g(E)\,dE = \frac{8\sqrt{2}\pi m^{3/2}}{h^3}V\int_{E_1}^{E_2} E^{1/2}dE = \frac{8\sqrt{2}\pi m^{3/2}}{h^3}V\frac{2}{3}\left(E_2^{3/2}-E_1^{3/2}\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \frac{16\sqrt{2}\pi\left(9.11\times10^{-31}\text{kg}\right)^{3/2}}{3\left(6.63\times10^{-34}\text{J•s}\right)^{3}}\left(0.1\text{m}\right)^{3}\left[\left(6.2\text{eV}\right)^{3/2}-\left(4.0\text{eV}\right)^{3/2}\right]\left(1.60\times10^{-19}\text{ J/eV}\right)^{3/2}$$

$$= 3.365\times10^{25} \approx \boxed{3\times10^{25}}$$

78. (*a*) For the glass to be transparent to the photon, the photon must have less energy than 1.14 eV, and so the wavelength of the photon must be longer than the wavelength corresponding to 1.14 eV.

$$E_{\text{band gap}} = \frac{hc}{\lambda_{\min}} \quad \rightarrow$$

$$\lambda_{\min} = \frac{hc}{E_{\text{band gap}}} = \frac{\left(6.63\times10^{-34}\text{J•s}\right)\left(3.00\times10^{8}\text{ m/s}\right)}{\left(1.14\text{eV}\right)\left(1.60\times10^{-19}\text{ J/eV}\right)} = 1.09\times10^{-6}\text{m} \quad \rightarrow \quad \boxed{\lambda > 1.09\times10^{-6}\text{m}}$$

The minimum wavelength for transparency is in the infrared region of the spectrum. Since IR has longer wavelengths than visible light, the silicon would not be transparent for visible light. The silicon would be opaque, as in Example 40-14.

(*b*) The minimum possible band gap energy for light to be transparent would mean that the band gap energy would have to be larger than the most energetic visible photon. The most energetic photon corresponds to the shortest wavelength, which is 450 nm in this problem.

$$E_{\text{band gap}} > E_{\lambda_{\min}} = \frac{hc}{\lambda_{\min}} = \frac{\left(6.63\times10^{-34}\text{J•s}\right)\left(3.00\times10^{8}\text{ m/s}\right)}{\left(450\times10^{-9}\text{m}\right)\left(1.60\times10^{-19}\text{ J/eV}\right)} = 2.7625\text{eV} \approx \boxed{2.8\text{eV}}$$

79. The photon with the maximum wavelength for absorption must have an energy equal to the energy gap.

$$E_g = hf = \frac{hc}{\lambda} = \frac{\left(6.63\times10^{-34}\text{J•s}\right)\left(3.00\times10^{8}\text{m/s}\right)}{\left(1.60\times10^{-19}\text{J/eV}\right)\left(1.92\times10^{-3}\text{m}\right)} = \boxed{6.47\times10^{-4}\text{eV}}$$

80. (*a*) The electrons will not be moving fast enough at this low temperature to use relativistic expressions, so the momentum is just the mass times the speed. The kinetic energy of the electrons can be found from the temperature, by Eq. 18-4. The kinetic energy is used to calculate the momentum, and the momentum is used to calculate the wavelength.

$$K = \tfrac{3}{2}kT = \frac{p^2}{2m} \quad \rightarrow \quad p = \sqrt{3mkT}$$

$$\lambda = \frac{h}{p} = \frac{h}{\sqrt{3mkT}} = \frac{\left(6.63\times10^{-34}\text{J•s}\right)}{\sqrt{3\left(9\times10^{-31}\text{kg}\right)\left(1.38\times10^{-23}\text{ J/K}\right)\left(300\text{K}\right)}} = 6.27\times10^{-9}\text{m} \approx \boxed{6\text{nm}}$$

(*b*) The wavelength is much longer than the opening, and so electrons at this temperature would experience diffraction when passing through the lattice.

81. The photon with the longest wavelength has the minimum energy.

$$E_g = \frac{hc}{\lambda} = \frac{\left(6.63\times10^{-34}\text{J•s}\right)\left(3.00\times10^{8}\text{m/s}\right)}{\left(1.60\times10^{-19}\text{J/eV}\right)\left(1100\times10^{-9}\text{m}\right)} = 1.130\text{eV} \approx \boxed{1.1\text{eV}}$$

If the energy gap is any larger than this, some solar photons will not have enough energy to cause an electron to jump levels, and so will not be absorbed.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

82. The energy gap is related to photon wavelength by $E_g = hf = hc/\lambda$. Use this for both colors of LED.

Green: $E_g = \dfrac{(6.63\times10^{-34}\,\text{J•s})(3.00\times10^{8}\,\text{m/s})}{(1.60\times10^{-19}\,\text{J/eV})(525\times10^{-9}\,\text{m})} = \boxed{2.37\,\text{eV}}$

Blue: $E_g = \dfrac{(6.63\times10^{-34}\,\text{J•s})(3.00\times10^{8}\,\text{m/s})}{(1.60\times10^{-19}\,\text{J/eV})(465\times10^{-9}\,\text{m})} = \boxed{2.67\,\text{eV}}$

83. The arsenic ion has a charge of +1, since we consider the ion as having been formed by removing one electron from the arsenic atom. Thus the effective Z will be 1, and we can use the Bohr theory results for hydrogen. We also substitute $K\epsilon_0$ in place of ϵ_0.

(*a*) The Bohr energy is given in Eq. 37-14a and b. The binding energy is the opposite of the ground state energy, so we use $n = 1$.

$$E_{\text{binding}} = \frac{Z^2e^4m}{8(K\epsilon_0)^2h^2}\frac{1}{n^2} = \frac{1}{K^2}\left(\frac{Z^2e^4m}{8\epsilon_0^2h^2}\right) = \frac{1}{12^2}(13.6\,\text{eV}) = \boxed{0.094\,\text{eV}}$$

(*b*) The Bohr radius is given in Eq. 37-11.

$$r_1 = \frac{h^2(K\epsilon_0)}{\pi mZe^2} = K\frac{h^2\epsilon_0}{\pi me^2} = 12\left(0.529\times10^{-10}\,\text{m}\right) = \boxed{6.3\times10^{-10}\,\text{m}}$$

84. From Eq. 25-13, the number of charge carriers per unit volume in a current is given by $n = \dfrac{I}{ev_{\text{drift}}A}$, where v_{drift} is the drift velocity of the charge carriers, and *A* is the cross-sectional area through which the carriers move. From Eq. 27-14, the drift velocity is given by $v_{\text{drift}} = \dfrac{\mathscr{E}_{\text{H}}}{Bd}$, where $\mathscr{E}_{\text{H}}$ is the Hall-effect voltage and *d* is the width of the strip carrying the current (see Figure 27-32). The distance *d* is the shorter dimension on the "top" of Figure 40-47. We combine these equations to find the density of charge carriers. We define the thickness of the current-carrying strip by $t = A/d$.

$$n = \frac{I}{ev_{\text{drift}}A} = \frac{IBd}{e\mathscr{E}_{\text{H}}A} = \frac{IB}{e\mathscr{E}_{\text{H}}t} = \frac{(0.28\times10^{-3}\,\text{A})(1.3\,\text{T})}{(1.60\times10^{-19}\,\text{C})(0.018\,\text{V})(1.0\times10^{-3}\,\text{m})} = 1.264\times10^{20}\,\text{electrons/m}^3$$

The actual density of atoms per unit volume in the silicon is found from the density and the atomic weight. We let that be represented by *N*.

$$N = (2330\,\text{kg/m}^3)\left(\frac{1\,\text{mole}}{28.0855\times10^{-3}\,\text{kg}}\right)\left(\frac{6.02\times10^{23}\,\text{atoms}}{1\,\text{mole}}\right) = 4.994\times10^{28}\,\text{atoms/m}^3$$

$$\frac{n}{N} = \frac{1.264\times10^{20}\,\text{electrons/m}^3}{4.994\times10^{28}\,\text{atoms/m}^3} = \boxed{2.5\times10^{-9}\,\text{electrons/atom}}$$

85. We assume the 130 V value is given to the nearest volt.

(*a*) The current through the load resistor must be maintained at a constant value.

$$I_{\text{load}} = \frac{V_{\text{output}}}{R_{\text{load}}} = \frac{(130\,\text{V})}{(18.0\,\text{k}\Omega)} = 7.22\,\text{mA}$$

At the minimum supply voltage, there will be no current through the diode, so the current through *R* is also 7.22 mA. The supply voltage is equal to the voltage across *R* plus the output voltage.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$V_R = I_{\text{load}}R = (7.22\,\text{mA})(2.80\,\text{k}\Omega) = 20.2\,\text{V} \;;\; V_{\substack{\text{supply}\\\text{min}}} = V_R + V_{\text{output}} = \boxed{150\,\text{V}}$$

At the maximum supply voltage, the current through the diode will be 120 mA, and so the current through R is 127 mA.

$$V_R = I_{\text{load}}R = (127.22\,\text{mA})(2.80\,\text{k}\Omega) = 356\,\text{V} \;;\; V_{\substack{\text{supply}\\\text{max}}} = V_R + V_{\text{output}} = \boxed{486\,\text{V}}$$

(*b*) The supply voltage is fixed at 245 V, and the output voltage is still to be 130 V. The voltage across R is fixed at $245\,\text{V} - 130\,\text{V} = 115\,\text{V}$. We calculate the current through R.

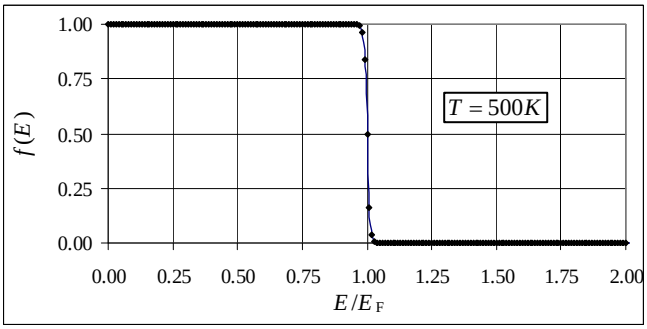
$$I_R = \frac{V_R}{R} = \frac{(115\,\text{V})}{(2.80\,\text{k}\Omega)} = 41.1\,\text{mA}$$

If there is no current through the diode, this current will be in the load resistor.

$$R_{\text{load}} = \frac{V_{\text{load}}}{I_{\text{load}}} = \frac{130\,\text{V}}{41.1\,\text{mA}} = 3.16\,\text{k}\Omega$$

If R_{load} is less than this, there will be a greater current through R, meaning a greater voltage drop across R, and a smaller voltage across the load. Thus regulation would be lost, so $3.16\,\text{k}\Omega$ is the minimum load resistance for regulation.

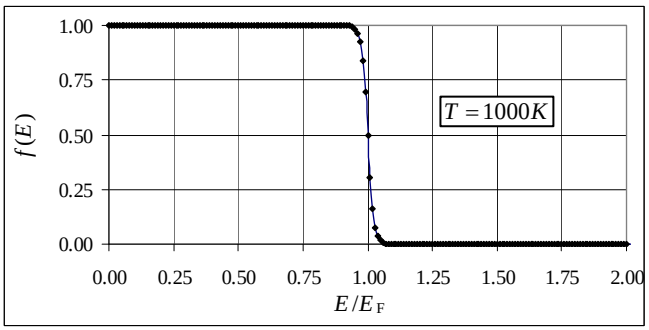
If R_{load} is greater than $3.16\,\text{k}\Omega$, the current through R_{load} will have to decrease in order for the voltage to be regulated, which means there must be current through the diode. The current through the diode is 41.1 mA when R_{load} is infinite, which is less than the diode maximum of 120 mA. Thus the range for load resistance is $\boxed{3.16\,\text{k}\Omega \le R_{\text{load}} < \infty.}$



86. The voltage as graphed in Figure 40-40c decays exponentially, according to Eq. 26-9b. As suggested in the problem, we use a linear approximation for the decay, using an expansion from Appendix A-3. From Figure 40-40c, we see that the decay lasts for approximately one-half of a cycle, before it increases back to the peak value.

$$V_{\text{min}} = V_{\text{peak}}e^{-t/\tau} \;\rightarrow\; \frac{V_{\text{min}}}{V_{\text{peak}}} = e^{-t/\tau} \approx 1 - \frac{t}{\tau} = 1 - \frac{t}{RC} = 1 - \frac{\frac{1}{2}\left(\frac{1}{60}\,\text{s}\right)}{\left(7.8\times10^{3}\,\Omega\right)\left(36\times10^{-6}\,\text{F}\right)} = 0.97$$

The voltage will decrease 3% from its maximum, or 1.5% above and below its average.



87. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH40.XLS," on tab "Problem 40.87."

(*a*)

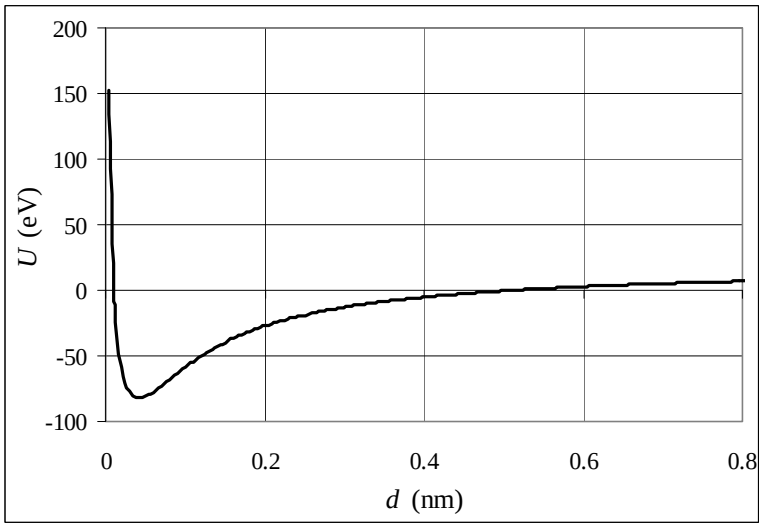
(*b*)

(*c*)

(*d*)

We see that for temperatures even as high as 1000 K, there is very little probability of electrons being above the Fermi level. Only when the temperature gets quite high do we see a significant increase in the probability of electrons to have an energy higher than the Fermi energy.

88. (*a*) The total potential energy is due to the electron-electron interaction, the proton-proton interaction, and 4 electron-proton interactions.



$$U = U_{\text{e-e}} + U_{\text{p-p}} + 4U_{\text{p-e}} = \frac{e^2}{4\pi\varepsilon_0}\frac{1}{d} + \frac{e^2}{4\pi\varepsilon_0}\frac{1}{r_0} + 4\left(-\frac{e^2}{4\pi\varepsilon_0}\right)\frac{1}{\sqrt{\left(\tfrac{1}{2}d\right)^2 + \left(\tfrac{1}{2}r_0\right)^2}}$$

$$= \boxed{\frac{e^2}{4\pi\varepsilon_0}\left(\frac{1}{d} + \frac{1}{r_0} - \frac{8}{\sqrt{r_0^2 + d^2}}\right)}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) U has a minimum at $d \approx \boxed{0.043\,\text{nm}}$. $U < 0$ for the approximate range $0.011\,\text{nm} \le d \le 0.51\,\text{nm}$.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH40.XLS," on tab "Problem 40.88b."

(*c*) To find the point of greatest stability, set the derivative of U with respect to d (indicated by U') equal to 0 and solve for d.

$$U = \frac{e^2}{4\pi\varepsilon_0}\left(\frac{1}{d} + \frac{1}{r_0} - \frac{8}{\sqrt{r_0^2 + d^2}}\right) \rightarrow$$

$$U' = \frac{e^2}{4\pi\varepsilon_0}\left(-\frac{1}{d^2} - \left(-\frac{1}{2}\right)\frac{8(2d)}{\left(r_0^2 + d^2\right)^{3/2}}\right) = \frac{e^2}{4\pi\varepsilon_0}\left(\frac{8d}{\left(r_0^2 + d^2\right)^{3/2}} - \frac{1}{d^2}\right) = 0 \rightarrow$$

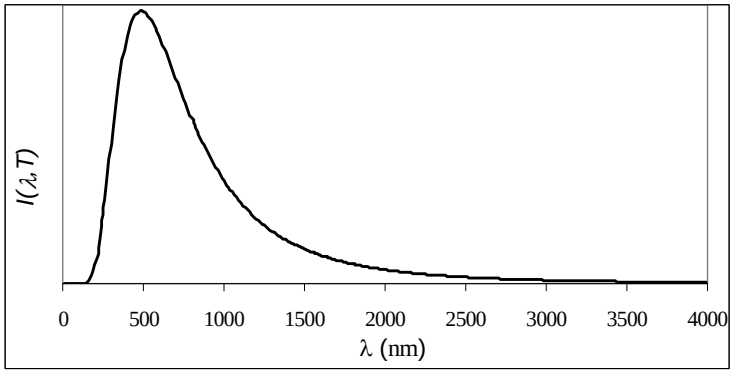
$$\frac{8d}{\left(r_0^2 + d^2\right)^{3/2}} = \frac{1}{d^2} \rightarrow 8d^3 = \left(r_0^2 + d^2\right)^{3/2} \rightarrow 2d = \sqrt{\left(r_0^2 + d^2\right)} \rightarrow$$

$$4d^2 = r_0^2 + d^2 \rightarrow d = \frac{r_0}{\sqrt{3}} = \frac{0.074}{\sqrt{3}} = \boxed{0.0427\,\text{nm}}$$

89. We first find the wavelength for a photon that has 1.14 eV of energy. This is the maximum wavelength that will be able to make electron-hole pairs.

$$E_{\text{gap}} = \frac{hc}{\lambda} \rightarrow \lambda = \frac{hc}{E_{\text{gap}}} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(1.14\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 1.09\times10^{-6}\,\text{m} = 1090\,\text{nm}$$

Any wavelength shorter than 1100 nm will be effective. The $1000\,\text{W/m}^2$ value includes all wavelengths of solar photons reaching the Earth, so we need to find what fraction of solar photons have wavelengths below 1100 nm. We do this using the Planck formula, from Section 37-1. We find the following using numeric integration, for a temperature of 6000 K.



$$\text{fraction of effective photons} = \frac{\int_0^{1100\,\text{nm}} \frac{2\pi hc^2\lambda^{-5}}{e^{hc/\lambda kT} - 1}\,d\lambda}{\int_0^{\infty} \frac{2\pi hc^2\lambda^{-5}}{e^{hc/\lambda kT} - 1}\,d\lambda}$$

The Planck function is shown in the figure for T = 6000 K. We approximated the upper limit for the full integration as 4000 nm, and obtained a ratio of 0.79. Thus we use an effective solar energy input of $790\,\text{W/m}^2$. To estimate the number of incoming photons, we use an average photon wavelength of 500 nm, estimated simply by looking at the Planck function graph. We also assume that each

photon produces only one electron-hole pair, even though many of them would have enough energy to create more than one.

The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH40.XLS," on tab "Problem 40.89."

$$\frac{I}{A} = \left(\frac{\text{Solar energy}}{\text{s}\bullet\text{m}^2}\right)\left(\frac{\text{1 "average" photon}}{\text{Energy for 500 nm photon}}\right)\left(\frac{\text{1 electron produced}}{\text{1 solar photon}}\right)\left(\frac{\text{Charge}}{\text{electron}}\right)$$

$$= \left(790\,\text{W/m}^2\right)\left(\frac{\lambda}{hc}\right)\left(1.60\times10^{-19}\,\text{C}\right) = \left(790\,\text{W/m}^2\right)\frac{\left(500\times10^{-9}\,\text{m}\right)\left(1.60\times10^{-19}\,\text{C}\right)}{\left(6.63\times10^{-34}\,\text{J}\bullet\text{s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}$$

$$= 318\,\text{C/s}\bullet\text{m}^2 = \boxed{32\,\text{mA/cm}^2}$$

CHAPTER 41: Nuclear Physics and Radioactivity

Responses to Questions

1. All isotopes of the same element have the same number of protons in their nuclei (and electrons in the atom) and will have very similar chemical properties. Isotopes of the same element have different numbers of neutrons in their nuclei and therefore different atomic masses.

2. (*a*) uranium; (*b*) nitrogen; (*c*) hydrogen; (*d*) strontium; (*e*) berkelium. The element is determined by the atomic number.

3. Z is the number of protons and N is the number of neutrons.
(*a*) $Z = 92$, $N = 140$; (*b*) $Z = 7$, $N = 11$; (*c*) $Z = 1$, $N = 0$; (*d*) $Z = 38$, $N = 44$; (*e*) $Z = 97$, $N = 150$.

4. If there are 88 nucleons and 50 neutrons, then there are 38 protons. Strontium is the element with 38 protons.

5. The atomic masses given in the periodic table are averaged over the isotopes of the element in the percentages in which they occur in nature. For instance, the most common form of hydrogen has one proton and no neutrons, but other naturally occurring isotopes include deuterium (one proton and one neutron) and tritium (one proton and 2 neutrons). These latter two are much less common, and the resulting "weighted average" for the mass of hydrogen is 1.0079.

6. A force other than the gravitational force or the electromagnetic force is necessary to explain the stability of nuclei. In most nuclei, several protons and neutrons are confined to a very small space. The gravitational attractive force between the nucleons is very small compared with electromagnetic repulsion between the protons. The strong nuclear force overcomes the electromagnetic repulsion and holds the nucleus together.

7. The strong force and the electromagnetic force are two of the four fundamental forces in nature. They are both involved in holding atoms together: the strong force binds quarks into nucleons and nucleons together in the nucleus; the electromagnetic force is responsible for binding negatively-charged electrons to positively-charged nuclei and atoms into molecules. The strong force is the strongest of the four fundamental forces; the electromagnetic force is about 100 times weaker at distances on the order of 10^{-17} m. The strong force operates at short range and is negligible for distances greater than about the size of the nucleus. The electromagnetic force is a long range force that decreases as the inverse square of the distance between the two interacting charged particles. The electromagnetic force operates only between charged particles. The strong force is always attractive; the electromagnetic force can be attractive or repulsive. Both these forces have mediating field particles associated with them. The gluon is the particle for the strong force and the photon is the particle for the electromagnetic force.

8. Chemical processes are the result of interactions between electrons. Radioactivity is not affected by the external conditions that normally affect chemical processes, such as temperature, pressure, or strong chemical reagents. Therefore, radioactivity is not a chemical process, but a nuclear one. In addition, the energies associated with radioactivity are generally larger than energies corresponding to electron orbital transitions, indicating that radioactivity is a nuclear process.

9. The resulting nuclide for gamma decay is the same isotope in a lower energy state:
$${}^{64}_{29}\mathrm{Cu}^{*} \rightarrow {}^{64}_{29}\mathrm{Cu} + \gamma\,.$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The resulting nuclide for beta-minus decay is an isotope of zinc, ${}^{64}_{30}\text{Zn}$:

${}^{64}_{29}\text{Cu} \rightarrow {}^{64}_{30}\text{Zn} + \text{e}^- + \bar{\nu}$.

The resulting nuclide for beta-plus decay is an isotope of nickel, ${}^{64}_{28}\text{Ni}$:

${}^{64}_{29}\text{Cu} \rightarrow {}^{64}_{28}\text{Ni} + \text{e}^+ + \nu$.

10. ${}^{238}_{92}\text{U}$ decays by alpha emission into ${}^{234}_{90}\text{Th}$, which has 144 neutrons.

11. Alpha (α) particles are helium nuclei. Each α particle consists of 2 protons and 2 neutrons, and therefore has a charge of +2*e* and an atomic mass value of 4 u. Beta (β) particles are electrons (beta-minus) or positrons (beta-plus). Electrons have a charge of –*e* and positrons have a charge of +*e*. In terms of mass, beta particles are much lighter than protons or neutrons, by a factor of about 2000, so are lighter than alpha particles by a factor of about 8000. Gamma (γ) particle are photons. They have no rest mass and no charge.

12. (*a*) Magnesium is formed: ${}^{24}_{11}\text{Na} \rightarrow {}^{24}_{12}\text{Mg} + \text{e}^- + \bar{\nu}$.

(*b*) Neon is formed: ${}^{22}_{11}\text{Na} \rightarrow {}^{22}_{10}\text{Ne} + \text{e}^+ + \nu$.

(c) Lead is formed: ${}^{210}_{84}\text{Po} \rightarrow {}^{206}_{82}\text{Pb} + {}^{4}_{2}\text{He}$.

13. (*a*) Sulfur is formed: ${}^{32}_{15}\text{Pb} \rightarrow {}^{32}_{16}\text{S} + \text{e}^- + \bar{\nu}$.

(*b*) Chlorine is formed: ${}^{35}_{16}\text{S} \rightarrow {}^{35}_{17}\text{Cl} + \text{e}^- + \bar{\nu}$.

(c) Thallium is formed: ${}^{211}_{83}\text{Bi} \rightarrow {}^{207}_{81}\text{Tl} + {}^{4}_{2}\text{He}$.

14. (*a*) ${}^{45}_{21}\text{Sc}$; (*b*) ${}^{58}_{29}\text{Cu}$; (*c*) $\text{e}^+ + \nu$; (*d*) ${}^{230}_{92}\text{U}$; (*e*) $\text{e}^- + \bar{\nu}$

15. The two extra electrons held by the newly formed thorium will be very loosely held, as the number of protons in the nucleus will have been reduced from 92 to 90, reducing the nuclear charge. It will be easy for these extra two electrons to escape from the thorium atom through a variety of mechanisms.

16. When a nucleus undergoes either β^- or β^+ decay it becomes a different element, since it has either converted a neutron to a proton or a proton to a neutron and therefore its atomic number has changed. The energy levels of the atomic electrons will adjust to become the energy levels of the new element. Photons are likely to be emitted from the atom as electrons change energies to occupy the new levels.

17. Alpha particles from an alpha-emitting nuclide are part of a two-body decay. The energy carried off by the decay fragments is determined by the principles of conservation of energy and of momentum. With only two decay fragments, these two constraints require the alpha particles to be monoenergetic. Beta particles from a beta-emitting nucleus are part of a three-body decay. Again, the energy carried off by all of the decay fragments is determined by the principles of conservation of energy and of momentum. However, with three decay fragments, the energy distribution between the fragments is not determined by these two constraints. The beta particles will therefore have a range of energies.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

18. Below. During electron capture, a proton in the nucleus becomes a neutron. Therefore, the isotopes that undergo electron capture will most likely be those that have too few neutrons in the nucleus (compared to their number of protons) and will lie below the line of stability in Figure 41-2.

19. No. Hydrogen has only one proton. Deuterium has one proton and one neutron. Neither has the two protons and two neutrons required to form an alpha particle.

20. Many artificially produced radioactive isotopes have very short half-lives, and so are rare in nature because they do not last long if they are produced naturally. Many of these isotopes also have a very high energy of formation, which is generally not available in nature.

21. No. At the end of one month, ½ the sample will remain. At the end of two months, ¼ of the original sample will remain.

22. For $Z > 92$, the short range of the attractive strong nuclear force means that no number of neutrons is able to overcome the electrostatic repulsion of the large concentration of protons.

23. Helium-3, ${}^{3}_{2}\mathrm{He}$, will be the other particle released. There are a total of four protons and three neutrons in the reactant particles. The alpha particle carries off two protons and two neutrons, leaving two protons and one neutron.

24. No. Carbon-14 dating can only be used to date objects that were once living. The stone used to build walls was never alive.

25. In β decay, a neutrino and a β particle (electron or positron) will be emitted from the nucleus, and the number of protons in the nucleus changes. Because there are three decay products (the neutrino, the β particle, and the nucleus), the momentum of the β particle can have a range of values. In internal conversion, only an electron is emitted from the atom, and the number of protons in the nucleus stays the same. Because there are only two decay products (the electron and the nucleus), the electron will have a unique momentum and, therefore, a unique energy.

26. Figure 41-6 shows the potential energy curve for an alpha particle and daughter nucleus for the case of radioactive nuclei. The alpha particle tunnels through the barrier from point A to point B in the figure. In the case of stable nuclei, the probability of this happening must be essentially zero. The maximum height of the Coulomb potential energy curve must be larger and/or the Q-value of the reaction must be smaller so that the probability of tunneling is extremely low.

27. The decay series of Figure 41-12 begins with a nucleus that has many more neutrons than protons and lies far above the line of stability in Figure 41-2. In a β^+ decay, a proton is converted to a neutron, which would take the nuclei in this decay series farther from the line of stability and is not energetically preferred.

28. There are four alpha particles and four β^- particles (electrons) emitted, no matter which decay path is chosen. The nucleon number drops by 16 as ${}^{222}_{86}\mathrm{Rn}$ decays into ${}^{206}_{82}\mathrm{Pb}$ ${}^{206}\mathrm{Pb}$, indicating the presence of four alpha decays. The proton number only drops by four, from $Z = 86$ to $Z = 82$, but four alpha decays would result in a decrease of eight protons. Four β^- decays will convert four neutrons into protons, making the decrease in the number of protons only four, as required. (See Figure 41-12.)

Solutions to Problems

1. Convert the units from MeV/c^2 to atomic mass units.

$$m = \left(139\,\text{MeV}/c^2\right)\left(\frac{1\,\text{u}}{931.49\,\text{MeV}/c^2}\right) = \boxed{0.149\,\text{u}}$$

2. The α particle is a helium nucleus and has $A = 4$. Use Eq. 41-1.

$$r = \left(1.2\times10^{-15}\,\text{m}\right)A^{\frac{1}{3}} = \left(1.2\times10^{-15}\,\text{m}\right)(4)^{\frac{1}{3}} = \boxed{1.9\times10^{-15}\,\text{m}} = 1.9\,\text{fm}$$

3. The radii of the two nuclei can be calculated with Eq. 41-1. Take the ratio of the two radii.

$$\frac{r_{238}}{r_{232}} = \frac{\left(1.2\times10^{-15}\,\text{m}\right)(238)^{1/3}}{\left(1.2\times10^{-15}\,\text{m}\right)(232)^{1/3}} = \left(\frac{238}{232}\right)^{1/3} = 1.0085$$

So the radius of ${}^{238}_{92}\text{U}$ is $\boxed{0.85\%}$ larger than the radius of ${}^{232}_{92}\text{U}$.

4. Use Eq. 41-1 for both parts.

(*a*) $r = \left(1.2\times10^{-15}\,\text{m}\right)A^{1/3} = \left(1.2\times10^{-15}\,\text{m}\right)(112)^{1/3} = \boxed{5.8\times10^{-15}\,\text{m}} = 5.8\,\text{fm}$

(*b*) $r = \left(1.2\times10^{-15}\,\text{m}\right)A^{1/3} \;\rightarrow\; A = \left(\frac{r}{1.2\times10^{-15}\,\text{m}}\right)^3 = \left(\frac{3.7\times10^{-15}\,\text{m}}{1.2\times10^{-15}\,\text{m}}\right)^3 = 29.3 \approx \boxed{29}$

5. To find the rest mass of an α particle, we subtract the rest mass of the two electrons from the rest mass of a helium atom:

$$m_\alpha = m_{\text{He}} - 2m_{\text{e}}$$
$$= \left(4.002603\,\text{u}\right)\left(931.5\,\text{MeV}/\text{u}c^2\right) - 2\left(0.511\,\text{MeV}/c^2\right) = \boxed{3727\,\text{MeV}/c^2}$$

This is less than the sum of the masses of two protons and two neutrons because of the binding energy.

6. Each particle would exert a force on the other through the Coulomb electrostatic force. The distance between the particles is twice the raiius of one of the particles. The Coulomb force is given by Eq. 21-2.

$$F = \frac{1}{4\pi\varepsilon_0}\frac{q_\alpha q_\alpha}{\left(2r_\alpha\right)^2} = \frac{\left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\left[(2)\left(1.60\times10^{-19}\,\text{C}\right)\right]^2}{\left[(2)\left(4^{1/3}\right)\left(1.2\times10^{-15}\,\text{m}\right)\right]^2} = 63.41\,\text{N} \approx \boxed{63\,\text{N}}$$

The acceleration is found from Newton's second law. We use the mass of a "bare" alpha calculated in Problem 5.

$$F = ma \;\rightarrow\; a = \frac{F}{m} = \frac{63.41\,\text{N}}{3727\,\text{MeV}/c^2\left(\frac{1.6605\times10^{-27}\,\text{kg}}{931.49\,\text{MeV}/c^2}\right)} = \boxed{9.5\times10^{27}\,\text{m}/\text{s}^2}$$

7. (*a*) The mass of a nucleus with mass number *A* is approximately (*A* u) and its radius is $r = \left(1.2 \times 10^{-15}\ \text{m}\right) A^{1/3}$. Calculate the density.

$$\rho = \frac{m}{V} = \frac{A\left(1.66 \times 10^{-27}\ \text{kg/u}\right)}{\frac{4}{3}\pi r^3} = \frac{A\left(1.66 \times 10^{-27}\ \text{kg/u}\right)}{\frac{4}{3}\pi\left(1.2 \times 10^{-15}\ \text{m}\right)^3 A} = 2.293 \times 10^{17}\ \text{kg/m}^3 \approx$$

$$\approx \boxed{2.3 \times 10^{17}\ \text{kg/m}^3}$$

We see that this is independent of *A*.

(*b*) We find the radius from the mass and the density.

$$M = \rho \tfrac{4}{3}\pi R^3 \quad \rightarrow \quad R = \left(\frac{3M}{4\pi\rho}\right)^{1/3} = \left[\frac{3\left(5.98 \times 10^{24}\ \text{kg}\right)}{4\pi\left(2.293 \times 10^{17}\ \text{kg/m}^3\right)}\right]^{1/3} = 184\ \text{m} \approx \boxed{180\ \text{m}}$$

(*c*) We set the density of the Earth equal to the density of the uranium nucleus. We approximate the mass of the uranium nucleus as 238 u.

$$\rho_{\text{Earth}} = \rho_U \quad \rightarrow \quad \frac{M_{\text{Earth}}}{\frac{4}{3}\pi R_{\text{Earth}}^3} = \frac{m_{\text{U}}}{\frac{4}{3}\pi r_{\text{U}}^3} \quad \rightarrow$$

$$r_{\text{U}} = R_{\text{Earth}}\left(\frac{m_{\text{U}}}{M_{\text{Earth}}}\right)^{1/3} = \left(6.38 \times 10^6\ \text{m}\right)\left[\frac{238\left(1.66 \times 10^{-27}\ \text{kg}\right)}{5.98 \times 10^{24}\ \text{kg}}\right]^{1/3} = \boxed{2.58 \times 10^{-10}\ \text{m}}$$

8. Use Eq. 41-1 to find the value for *A*. We use uranium-238 since it is the most common isotope.

$$\frac{r_{\text{unknown}}}{r_{\text{U}}} = \frac{\left(1.2 \times 10^{-15}\ \text{m}\right) A^{1/3}}{r = \left(1.2 \times 10^{-15}\ \text{m}\right)(238)^{1/3}} = 0.5 \quad \rightarrow \quad A = 238(0.5)^3 = 29.75 \approx 30$$

From Appendix F, a stable nucleus with $A \approx 30$ is $\boxed{{}^{31}_{15}\text{P}}$.

9. The basic principle to use is that of conservation of energy. We assume that the centers of the two particles are located a distance from each other equal to the sum of their radii. That distance is used to calculate the initial electrical potential energy. Then we also assume that, since the nucleus is much heavier than the alpha, that the alpha has all of the final kinetic energy when the particles are far apart from each other (and so have no potential energy).

$$K_{\text{i}} + U_{\text{i}} = K_{\text{f}} + U_{\text{f}} \quad \rightarrow \quad 0 + \frac{1}{4\pi\varepsilon_0}\frac{q_\alpha q_{\text{Fm}}}{\left(r_\alpha + r_{\text{Fm}}\right)} = K_\alpha + 0 \quad \rightarrow$$

$$K_\alpha = \left(8.988 \times 10^9\ \text{N} \cdot \text{m}^2/\text{C}^2\right)\frac{(2)(100)\left(1.60 \times 10^{-19}\ \text{C}\right)^2}{\left(4^{1/3} + 257^{1/3}\right)\left(1.2 \times 10^{-15}\ \text{m}\right)\left(1.60 \times 10^{-19}\ \text{J/eV}\right)} = 3.017 \times 10^7\ \text{eV}$$

$$\approx \boxed{30\ \text{MeV}}$$

10. (*a*) The hydrogen atom is made of a proton and an electron.

$$\frac{m_{\text{p}}}{\left(m_{\text{p}} + m_{\text{e}}\right)} = \frac{\left(1.67 \times 10^{-27}\ \text{kg}\right)}{\left(1.67 \times 10^{-27}\ \text{kg} + 9.11 \times 10^{-31}\ \text{kg}\right)} = \boxed{0.99945}$$

(*b*) Compare the volume of the nucleus to the volume of the atom. The nuclear radius is given by Eq. 41-1. For the atomic radius we use the Bohr radius, given in Eq. 37-12.

$$\left(\frac{r_{\text{nucleus}}}{r_{\text{atom}}}\right)^3 = \left[\frac{\left(1.2 \times 10^{-15}\ \text{m}\right)}{\left(0.53 \times 10^{-10}\ \text{m}\right)}\right]^3 = \boxed{1.2 \times 10^{-14}}$$

11. Electron mass is negligible compared to nucleon mass, and one nucleon weighs about 1.0 atomic mass unit. Therefore, in a 1.0-kg object,

$$N = \frac{(1.0\,\text{kg})\left(6.02\times10^{26}\,\text{u/kg}\right)}{1.0\,\text{u/nucleon}} \approx \boxed{6\times10^{26}\,\text{nucleons.}}$$

No, it does not matter what the element is, because the mass of one nucleon is essentially the same for all elements.

12. The initial kinetic energy of the alpha must be equal to the electrical potential energy when the alpha just touches the uranium. The distance between the two particles is the sum of their radii.

$$K_\text{i} + U_\text{i} = K_\text{f} + U_\text{f} \quad\rightarrow\quad K_\alpha + 0 = 0 + \frac{1}{4\pi\varepsilon_0}\frac{q_\alpha q_\text{U}}{(r_\alpha + r_\text{U})} \quad\rightarrow$$

$$K_\alpha = \left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(2)(92)\left(1.60\times10^{-19}\,\text{C}\right)^2}{\left(4^{1/3}+238^{1/3}\right)\left(1.2\times10^{-15}\,\text{m}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 2.832\times10^7\,\text{eV}$$

$$\approx \boxed{28\,\text{MeV}}$$

13. From Figure 41–1, we see that the average binding energy per nucleon at A = 63 is about 8.7 MeV. Multiply this by the number of nucleons in the nucleus.

$$(63)(8.7\,\text{MeV}) = 548.1\,\text{MeV} \approx \boxed{550\,\text{MeV}}$$

14. Deuterium consists of one proton, one neutron, and one electron. Ordinary hydrogen consists of one proton and one electron. We use the atomic masses from Appendix F, and the electron masses cancel.

$$\begin{aligned}\text{Binding energy} &= \left[m\left({}^1_1\text{H}\right) + m\left({}^1_0\text{n}\right) - m\left({}^2_1\text{H}\right)\right]c^2 \\ &= \left[(1.007825\,\text{u}) + (1.008665\,\text{u}) - (2.014082\,\text{u})\right]c^2\left(931.5\,\text{MeV/u}c^2\right) \\ &= \boxed{2.243\,\text{MeV}}\end{aligned}$$

15. We find the binding energy of the last neutron from the masses of the isotopes.

$$\begin{aligned}\text{Binding energy} &= \left[m\left({}^{31}_{15}\text{P}\right) + m\left({}^1_0\text{n}\right) - m\left({}^{32}_{15}\text{P}\right)\right]c^2 \\ &= \left[(30.973762\,\text{u}) + (1.008665\,\text{u}) - (31.973907\,\text{u})\right]c^2\left(931.5\,\text{MeV}/c^2\right) \\ &= \boxed{7.94\,\text{MeV}}\end{aligned}$$

16. (*a*) ${}^7_3\text{Li}$ consists of three protons and three neutrons. We find the binding energy from the masses, using hydrogen atoms in place of protons so that we account for the mass of the electrons.

$$\begin{aligned}\text{Binding energy} &= \left[3m\left({}^1_1\text{H}\right) + 4m\left({}^1_0\text{n}\right) - m\left({}^7_3\text{Li}\right)\right]c^2 \\ &= \left[3(1.007825\,\text{u}) + 4(1.008665\,\text{u}) - (7.016005\,\text{u})\right]c^2\left(931.5\,\text{MeV}/c^2\right) \\ &= 39.24\,\text{MeV}\end{aligned}$$

$$\frac{\text{Binding energy}}{\text{nucleon}} = \frac{39.24\,\text{MeV}}{7\,\text{nucleons}} = \boxed{5.61\,\text{MeV/nucleon}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) ${}^{197}_{79}\text{Au}$ consists of 79 protons and 118 neutrons. We find the binding energy as in part (*a*).

$$\begin{aligned}\text{Binding energy} &= \left[79m\left({}^{1}_{1}\text{H}\right)+118m\left({}^{1}_{0}\text{n}\right)-m\left({}^{197}_{79}\text{Au}\right)\right]c^2 \\ &= \left[79(1.007825\,\text{u})+118(1.008665\,\text{u})-(196.966569\,\text{u})\right]c^2\left(931.5\,\text{MeV}/c^2\right) \\ &= 1559\,\text{MeV}\end{aligned}$$

$$\frac{\text{Binding energy}}{\text{nucleon}} = \frac{1559\,\text{MeV}}{197\,\text{nucleons}} = \boxed{7.91\,\text{MeV/nucleon}}$$

17. ${}^{23}_{11}\text{Na}$ consists of 11 protons and 12 neutrons. We find the binding energy from the masses:

$$\begin{aligned}\text{Binding energy} &= \left[11m\left({}^{1}_{1}\text{H}\right)+12m\left({}^{1}_{0}\text{n}\right)-m\left({}^{23}_{11}\text{Na}\right)\right]c^2 \\ &= \left[11(1.007825\,\text{u})+12(1.008665\,\text{u})-(22.989769\,\text{u})\right]c^2\left(931.5\,\text{MeV/u}c^2\right) \\ &= 186.6\,\text{MeV}\end{aligned}$$

$$\frac{\text{Binding energy}}{\text{nucleon}} = \frac{186.6\,\text{MeV}}{23} = \boxed{8.113\,\text{MeV/nucleon}}$$

We do a similar calculation for ${}^{24}_{11}\text{Na}$, consisting of 11 protons and 13 neutrons.

$$\begin{aligned}\text{Binding energy} &= \left[11m\left({}^{1}_{1}\text{H}\right)+13m\left({}^{1}_{0}\text{n}\right)-m\left({}^{24}_{11}\text{Na}\right)\right]c^2 \\ &= \left[11(1.007825\,\text{u})+13(1.008665\,\text{u})-(23.990963\,\text{u})\right]c^2\left(931.5\,\text{MeV/u}c^2\right) \\ &= 193.5\,\text{MeV}\end{aligned}$$

$$\frac{\text{Binding energy}}{\text{nucleon}} = \frac{193.5\,\text{MeV}}{24} = \boxed{8.063\,\text{MeV/nucleon}}$$

By this measure, the nucleons in ${}^{23}_{11}\text{Na}$ are more tightly bound than those in ${}^{24}_{11}\text{Na}$.

18. We find the required energy by calculating the difference in the masses.

(*a*) Removal of a proton creates an isotope of carbon. To balance electrons, the proton is included as a hydrogen atom: ${}^{15}_{7}\text{N} \rightarrow {}^{1}_{1}\text{H} + {}^{14}_{6}\text{C}$.

$$\begin{aligned}\text{Energy needed} &= \left[m\left({}^{14}_{6}\text{C}\right)+m\left({}^{1}_{1}\text{H}\right)-m\left({}^{15}_{7}\text{N}\right)\right]c^2 \\ &= \left[(14.003242\,\text{u})+(1.007825\,\text{u})-(15.000109\,\text{u})\right]\left(931.5\,\text{MeV/u}c^2\right) \\ &= \boxed{10.21\,\text{MeV}}\end{aligned}$$

(*b*) Removal of a neutron creates another isotope of nitrogen: ${}^{15}_{7}\text{N} \rightarrow {}^{1}_{0}\text{n} + {}^{14}_{7}\text{N}$.

$$\begin{aligned}\text{Energy needed} &= \left[m\left({}^{14}_{7}\text{N}\right)+m\left({}^{1}_{0}\text{n}\right)-m\left({}^{15}_{7}\text{N}\right)\right]c^2 \\ &= \left[(14.003074\,\text{u})+(1.008665\,\text{u})-(15.000109\,\text{u})\right]\left(931.5\,\text{MeV/u}c^2\right) \\ &= \boxed{10.83\,\text{MeV}}\end{aligned}$$

The nucleons are held by the attractive strong nuclear force. It takes less energy to remove the proton because there is also the repulsive electric force from the other protons.

19. (*a*) We find the binding energy from the masses.

$$\begin{aligned}\text{Binding Energy} &= \left[2m\left({}^{4}_{2}\text{He}\right)-m\left({}^{8}_{4}\text{Be}\right)\right]c^2 \\ &= \left[2(4.002603\,\text{u})-(8.005305\,\text{u})\right]c^2\left(931.5\,\text{MeV/u}c^2\right) = -0.092\,\text{MeV}\end{aligned}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

Because the binding energy is negative, the nucleus is unstable. It will be in a lower energy state as two alphas instead of a beryllium.

(*b*) We find the binding energy from the masses.

$$\text{Binding Energy} = \left[3m\left({}^{4}_{2}\text{He}\right) - m\left({}^{12}_{6}\text{C}\right)\right]c^2$$

$$= \left[3(4.002603\,\text{u}) - (12.000000\,\text{u})\right]c^2\left(931.5\,\text{MeV/u}c^2\right) = +7.3\,\text{MeV}$$

Because the binding energy is positive, the nucleus is stable.

20. The decay is ${}^{3}_{1}\text{H} \rightarrow {}^{3}_{2}\text{He} + {}^{0}_{-1}\text{e} + \bar{\nu}$. When we add one electron to both sides to use atomic masses, we see that the mass of the emitted β particle is included in the atomic mass of ${}^{3}_{2}\text{He}$. The energy released is the difference in the masses.

$$\text{Energy released} = \left[m\left({}^{3}_{1}\text{H}\right) - m\left({}^{3}_{2}\text{He}\right)\right]c^2$$

$$= \left[(3.016049\,\text{u}) - (3.016029\,\text{u})\right]c^2\left(931.5\,\text{MeV/u}c^2\right) = 0.019\,\text{MeV}$$

21. The decay is ${}^{1}_{0}\text{n} \rightarrow {}^{1}_{1}\text{p} + {}^{0}_{-1}\text{e} + \bar{\nu}$. The electron mass is accounted for if we use the atomic mass of ${}^{1}_{1}\text{H}$. If we ignore the recoil of the proton and the neutrino, and any possible mass of the neutrino, we get the maximum kinetic energy.

$$K_{\max} = \left[m\left({}^{1}_{0}\text{n}\right) - m\left({}^{1}_{1}\text{H}\right)\right]c^2 = \left[(1.008665\,\text{u}) - (1.007825\,\text{u})\right]c^2\left(931.5\,\text{MeV/u}c^2\right)$$

$$= 0.782\,\text{MeV}$$

22. For the decay ${}^{11}_{6}\text{C} \rightarrow {}^{10}_{5}\text{B} + {}^{1}_{1}\text{p}$, we find the difference of the initial and the final masses:

$$\Delta m = m\left({}^{11}_{6}\text{C}\right) - m\left({}^{10}_{5}\text{B}\right) - m\left({}^{1}_{1}\text{H}\right)$$

$$= (11.011434\,\text{u}) - (10.012937\,\text{u}) - (1.007825\,\text{u}) = -0.009328\,\text{u}$$

$$= (11.011433\,\text{u}) - (10.012936\,\text{u}) - (1.007825\,\text{u}) = -0.0099318\,\text{u}.$$

Since the final masses are more than the original mass, energy would not be conserved.

23. The wavelength is determined from the energy change between the states.

$$\Delta E = hf = h\frac{c}{\lambda} \quad \rightarrow \quad \lambda = \frac{hc}{\Delta E} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(0.48\,\text{MeV}\right)\left(1.60\times10^{-13}\,\text{J/MeV}\right)} = 2.6\times10^{-12}\,\text{m}$$

24. For each decay, we find the difference of the initial and the final masses. If the final mass is more than the initial mass, then the decay is not possible.

(*a*) $\Delta m = m\left({}^{232}_{92}\text{U}\right) + m\left({}^{1}_{0}\text{n}\right) - m\left({}^{233}_{92}\text{U}\right) = 232.037156\,\text{u} + 1.008665\,\text{u} - 233.039635\,\text{u} = 0.006816\,\text{u}$

Because an increase in mass is required, the decay is not possible.

(*b*) $\Delta m = m\left({}^{13}_{7}\text{N}\right) + m\left({}^{1}_{0}\text{n}\right) - m\left({}^{14}_{7}\text{N}\right) = 13.005739\,\text{u} + 1.008665\,\text{u} - 14.003074\,\text{u} = 0.011330\,\text{u}$

Because an increase in mass is required, the decay is not possible.

(*c*) $\Delta m = m\left({}^{39}_{19}\text{K}\right) + m\left({}^{1}_{0}\text{n}\right) - m\left({}^{40}_{19}\text{K}\right) = 38.963707\,\text{u} + 1.008665\,\text{u} - 39.963998\,\text{u} = 0.008374\,\text{u}$

Because an increase in mass is required, the decay is not possible.

25. (*a*) From Appendix F, ${}^{24}_{11}\text{Na}$ is a $\boxed{\beta^- \text{ emitter}}$.

(*b*) The decay reaction is $\boxed{{}^{24}_{11}\text{Na} \rightarrow {}^{24}_{12}\text{Mg} + \beta^- + \bar{\nu}}$. We add 11 electrons to both sides in order to use atomic masses. Then the mass of the beta is accounted for in the mass of the magnesium. The maximum kinetic energy of the β^- corresponds to the neutrino having no kinetic energy (a limiting case). We also ignore the recoil of the magnesium.

$$K_{\beta^-} = \left[m\left({}^{24}_{11}\text{Na}\right) - m\left({}^{24}_{12}\text{Mg}\right)\right]c^2$$

$$= \left[\left(23.990963\,\text{u}\right) - \left(23.985042\,\text{u}\right)\right]c^2\left(931.5\,\text{MeV/u}c^2\right) = \boxed{5.52\,\text{MeV}}$$

26. The kinetic energy of the electron will be maximum if the (essentially) massless neutrino has no kinetic energy. We also ignore the recoil energy of the sodium. The maximum kinetic energy of the reaction is then the *Q*-value of the reaction. Note that the "new" electron mass is accounted for by using atomic masses.

$$K = Q = \left[m\left({}^{23}_{10}\text{Ne}\right) - m\left({}^{23}_{11}\text{Na}\right)\right]c^2 == \left[\left(22.9945\,\text{u}\right) - \left(22.9898\,\text{u}\right)\right]c^2\left(931.5\,\text{MeV/u}c^2\right)$$

$$= \boxed{4.4\,\text{MeV}}$$

If the neutrino were to have all of the kinetic energy, then the minimum kinetic energy of the electron is $\boxed{0.}$ The sum of the kinetic energy of the electron and the energy of the neutrino must be the *Q*-value, and so the neutrino energies are $\boxed{0}$ and $\boxed{4.4\text{ MeV}}$, respectively.

27. (*a*) We find the final nucleus by balancing the mass and charge numbers.

$$Z(X) = Z(\text{U}) - Z(\text{He}) = 92 - 2 = 90$$

$$A(X) = A(\text{U}) - A(\text{He}) = 238 - 4 = 234$$

Thus the final nucleus is $\boxed{{}^{234}_{90}\text{Th}}$.

(*b*) If we ignore the recoil of the thorium, the kinetic energy of the α particle is equal to the *Q*-value of the reaction. The electrons are balanced.

$$K = Q = \left[m\left({}^{238}_{92}\text{U}\right) - m\left({}^{234}_{90}\text{Th}\right) - m\left({}^{4}_{2}\text{He}\right)\right]c^2 \quad \rightarrow$$

$$m\left({}^{234}_{90}\text{Th}\right) = m\left({}^{238}_{92}\text{U}\right) - m\left({}^{4}_{2}\text{He}\right) - \frac{K}{c^2}$$

$$= \left[238.050788\,\text{u} - 4.002603\,\text{u} - \frac{4.20\,\text{MeV}}{c^2}\left(\frac{1\,\text{u}}{931.5\,\text{MeV}/c^2}\right)\right]$$

$$= \boxed{234.04368\,\text{u}}$$

This answer assumes that the 4.20 MeV value does not limit the sig. fig. of the answer.

28. The reaction is ${}^{60}_{27}\text{Co} \rightarrow {}^{60}_{28}\text{Ni} + \beta^- + \bar{\nu}$. The kinetic energy of the β^- will be maximum if the (essentially) massless neutrino has no kinetic energy. We also ignore the recoil of the nickel.

$$K_\beta = \left[m\left({}^{60}\text{Co}\right) - m\left({}^{60}\text{Ni}\right)\right]c^2$$

$$= \left[\left(59.933822\,\text{u}\right) - \left(59.930791\,\text{u}\right)\right]c^2\left(931.5\,\text{MeV}/\text{u}c^2\right) = \boxed{2.82\,\text{MeV.}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

29. We use conservation of momentum – the momenta of the two particles must be equal and opposite if there are only two products. The energies are small enough that we may use non-relativistic relationships.

$$p_\alpha = p_X \quad \rightarrow \quad \sqrt{2m_\alpha K_\alpha} = \sqrt{2m_X K_X} \quad \rightarrow \quad K_X = \frac{m_\alpha}{m_X} K_\alpha = \frac{4}{256}(5.0\,\text{MeV}) = \boxed{0.078\,\text{MeV}}$$

30. For alpha decay we have ${}^{218}_{84}\text{Po} \rightarrow {}^{214}_{82}\text{Pb} + {}^{4}_{2}\text{He}$. We find the Q value.

$$\begin{aligned} Q &= \left[m\left({}^{218}_{84}\text{Po}\right) - m\left({}^{214}_{82}\text{Pb}\right) - m\left({}^{4}_{2}\text{He}\right) \right] c^2 \\ &= \left[218.008965\,\text{u} - 213.999805\,\text{u} - 4.002603\,\text{u} \right] c^2 \left(931.5\,\text{MeV/u}c^2 \right) \\ &= \boxed{6.108\,\text{MeV}} \end{aligned}$$

For beta decay we have ${}^{218}_{84}\text{Po} \rightarrow {}^{218}_{85}\text{At} + {}^{0}_{-1}\text{e} + \bar{\nu}$. We assume the neutrino is massless, and find the Q value.

$$\begin{aligned} Q &= \left[m\left({}^{218}_{84}\text{Po}\right) - m\left({}^{218}_{85}\text{At}\right) \right] c^2 \\ &= \left[218.008965\,\text{u} - 218.008694\,\text{u} \right] c^2 \left(931.5\,\text{MeV/u}c^2 \right) = \boxed{0.252\,\text{MeV}} \end{aligned}$$

31. (*a*) We find the final nucleus by balancing the mass and charge numbers.

$$Z(X) = Z(\text{P}) - Z(\text{e}) = 15 - (-1) = 16$$
$$A(X) = A(\text{P}) - A(\text{e}) = 32 - 0 = 32$$

Thus the final nucleus is $\boxed{{}^{32}_{16}\text{S}}$.

(*b*) If we ignore the recoil of the sulfur and the energy of the neutrino, the maximum kinetic energy of the electron is the Q-value of the reaction. The reaction is ${}^{32}_{15}\text{P} \rightarrow {}^{32}_{16}\text{S} + \beta^- + \bar{\nu}$. We add 15 electrons to each side of the reaction, and then we may use atomic masses. The mass of the emitted beta is accounted for in the mass of the sulfur.

$$K = Q = \left[m\left({}^{32}_{15}\text{P}\right) - m\left({}^{32}_{16}\text{S}\right) \right] c^2 \quad \rightarrow$$

$$m\left({}^{32}_{16}\text{S}\right) = m\left({}^{32}_{15}\text{P}\right) - \frac{K}{c^2} = \left[31.973907\,\text{u} - \frac{1.71\,\text{MeV}}{c^2}\left(\frac{1\,\text{u}}{931.5\,\text{MeV}/c^2} \right) \right] = \boxed{31.972071\,\text{u}}$$

32. We find the energy from the wavelength.

$$E = \frac{hc}{\lambda} = \frac{\left(6.63 \times 10^{-34}\,\text{J•s}\right)\left(3.00 \times 10^{8}\,\text{m/s}\right)}{\left(1.00 \times 10^{-13}\,\text{m}\right)\left(1.602 \times 10^{-19}\,\text{J/eV}\right)} = \boxed{12.4\,\text{MeV}}$$

This has to be a $\boxed{\gamma \text{ ray from the nucleus}}$ rather than a photon from the atom. Electron transitions do not involve this much energy. Electron transitions involve energies on the order of a few eV.

33. We add three electron masses to each side of the reaction ${}^{7}_{4}\text{Be} + {}^{0}_{-1}\text{e} \rightarrow {}^{7}_{3}\text{Li} + \nu$. Then for the mass of the product side, we may use the atomic mass of ${}^{7}_{3}\text{Li}$. For the reactant side, including the three electron masses and the mass of the emitted electron, we may use the atomic mass of ${}^{7}_{4}\text{Be}$. The energy released is the Q-value.

$$\begin{aligned} Q &= \left[m\left({}^{7}_{4}\text{Be}\right) - m\left({}^{7}_{3}\text{Li}\right) \right] c^2 \\ &= \left[\left(7.016930\,\text{u}\right) - \left(7.016005\,\text{u}\right) \right] c^2 \left(931.5\,\text{MeV/u}c^2 \right) = \boxed{0.862\,\text{MeV}} \end{aligned}$$

34. The emitted photon and the recoiling nucleus have the same magnitude of momentum. We find the recoil energy from the momentum. We assume the energy is small enough that we can use classical relationships.

$$p_\gamma = \frac{E_\gamma}{c} = p_{\mathrm{K}} = \sqrt{2m_{\mathrm{K}}K_{\mathrm{K}}} \quad \rightarrow$$

$$K_{\mathrm{K}} = \frac{E_\gamma^2}{2m_{\mathrm{K}}c^2} = \frac{(1.46\,\mathrm{MeV})^2}{2(39.96\,\mathrm{u})(931.5\,\mathrm{MeV/u}c^2)c^2} = 2.86\times10^{-5}\,\mathrm{MeV} = \boxed{28.6\,\mathrm{eV}}$$

35. The kinetic energy of the β^+ particle will be maximum if the (almost massless) neutrino has no kinetic energy. We ignore the recoil of the boron. Note that if the mass of one electron is added to the mass of the boron, then we may use atomic masses. We also must include the mass of the β^+. (See Problem 38 for details.)

$${}^{11}_{6}\mathrm{C} \rightarrow \left({}^{11}_{5}\mathrm{B} + {}^{0}_{-1}\mathrm{e}\right) + {}^{0}_{1}\beta^+ + \nu$$

$$K = \left[m\left({}^{11}_{6}\mathrm{C}\right) - m\left({}^{11}_{5}\mathrm{B}\right) - m\left({}^{0}_{-1}\mathrm{e}\right) - m\left({}^{0}_{1}\beta^+\right)\right]c^2 = \left[m\left({}^{11}_{6}\mathrm{C}\right) - m\left({}^{11}_{5}\mathrm{B}\right) - 2m\left({}^{0}_{-1}\mathrm{e}\right)\right]c^2$$

$$= \left[(11.011434\,\mathrm{u}) - (11.009305) - 2(0.00054858\,\mathrm{u})\right]c^2\left(931.5\,\mathrm{MeV/u}c^2\right) = \boxed{0.9612\,\mathrm{MeV}}$$

If the β^+ has no kinetic energy, then the maximum kinetic energy of the neutrino is also $\boxed{0.9612\,\mathrm{MeV}}$. The minimum energy of each is $\boxed{0}$, when the other has the maximum.

36. We assume that the energies are low enough that we may use classical kinematics. In particular, we will use $p = \sqrt{2mK}$. The decay is ${}^{238}_{92}\mathrm{U} \rightarrow {}^{234}_{90}\mathrm{Th} + {}^{4}_{2}\mathrm{He}$. If the uranium nucleus is at rest when it decays, the magnitude of the momentum of the two daughter particles must be the same.

$$p_\alpha = p_{\mathrm{Th}} \;;\; K_{\mathrm{Th}} = \frac{{p_{\mathrm{Th}}}^2}{2m_{\mathrm{Th}}} = \frac{{p_\alpha}^2}{2m_{\mathrm{Th}}} = \frac{2m_\alpha K_\alpha}{2m_{\mathrm{Th}}} = \frac{m_\alpha}{m_{\mathrm{Th}}}K_\alpha = \left(\frac{4\,\mathrm{u}}{234\,\mathrm{u}}\right)(4.20\,\mathrm{MeV}) = \boxed{0.0718\,\mathrm{MeV}}$$

The *Q*-value is the total kinetic energy produced.

$$Q = K_\alpha + K_{\mathrm{Th}} = 4.20\,\mathrm{MeV} + 0.0718\,\mathrm{MeV} = \boxed{4.27\,\mathrm{MeV}}$$

37. Both energy and momentum are conserved. Therefore, the momenta of the product particles are equal in magnitude. We assume that the energies involved are low enough that we may use classical kinematics; in particular, $p = \sqrt{2mK}$.

$$p_\alpha = p_{\mathrm{Pb}} \;;\; K_{\mathrm{Pb}} = \frac{p_{\mathrm{Pb}}^2}{2m_{\mathrm{Pb}}} = \frac{p_\alpha^2}{2m_{\mathrm{Pb}}} = \frac{2m_\alpha K_\alpha}{2m_{\mathrm{Pb}}} = \left(\frac{m_\alpha}{m_{\mathrm{Pb}}}\right)K_\alpha = \frac{4.0026}{205.97}K_\alpha$$

The sum of the kinetic energies of the product particles must be equal to the *Q*-value for the reaction.

$$K_{\mathrm{Pb}} + K_\alpha = \left[m\left({}^{210}_{84}\mathrm{Po}\right) - m\left({}^{206}_{82}\mathrm{Pb}\right) - m\left({}^{4}_{2}\mathrm{He}\right)\right]c^2 = \frac{4.0026}{205.97}K_\alpha + K_\alpha \quad \rightarrow$$

$$K_\alpha = \frac{\left[m\left({}^{210}_{84}\mathrm{Po}\right) - m\left({}^{206}_{82}\mathrm{Pb}\right) - m\left({}^{4}_{2}\mathrm{He}\right)\right]c^2}{\left(\frac{4.0026}{205.97} + 1\right)}$$

$$= \frac{\left[(209.982874\,\mathrm{u}) - (205.974465\,\mathrm{u}) - (4.002603\,\mathrm{u})\right]c^2}{\left(\frac{4.0026}{205.97} + 1\right)}\left(931.5\,\mathrm{MeV/u}c^2\right) = \boxed{5.31\,\mathrm{MeV}}$$

38. For the positron-emission process, ${}_{Z}^{A}\mathrm{N} \rightarrow {}_{Z-1}^{A}\mathrm{N}' + \mathrm{e}^{+} + \nu$. We must add Z electrons to the nuclear mass of N to be able to use the atomic mass, and so we must also add Z electrons to the reactant side. On the reactant side, we use $Z-1$ electrons to be able to use the atomic mass of N′. Thus we have 1 "extra" electron mass and the β-particle mass, which means that we must include 2 electron masses on the right-hand side. We find the Q-value given this constraint.

$$Q = \left[M_{\mathrm{P}} - \left(M_{\mathrm{D}} + 2m_{\mathrm{e}}\right)\right]c^2 = \left(M_{\mathrm{P}} - M_{\mathrm{D}} - 2m_{\mathrm{e}}\right)c^2.$$

39. (*a*) The decay constant can be found from the half-life, using Eq. 41-8.

$$\lambda = \frac{\ln 2}{T_{1/2}} = \frac{\ln 2}{4.5\times10^{9}\,\mathrm{yr}} = \boxed{1.5\times10^{-10}\,\mathrm{yr}^{-1}} = 4.9\times10^{-18}\,\mathrm{s}^{-1}$$

(*b*) The half-life can be found from the decay constant, using Eq. 41-8.

$$T_{1/2} = \frac{\ln 2}{\lambda} = \frac{\ln 2}{3.2\times10^{-5}\,\mathrm{s}^{-1}} = 21660\,\mathrm{s} = \boxed{6.0\,\mathrm{h}}$$

40. We find the half-life from Eq. 41-7d and Eq. 41-8.

$$R = R_0 e^{-\lambda t} = R_0 e^{-\frac{\ln 2}{T_{1/2}}t} \quad \rightarrow \quad T_{1/2} = -\frac{\ln 2}{\ln\dfrac{R}{R_0}}t = -\frac{\ln 2}{\ln\dfrac{320}{1280}}(3.6\,\mathrm{h}) = \boxed{1.8\,\mathrm{h}}$$

We can see this also from the fact that the rate dropped by a factor of 4, which takes 2 half-lives.

41. We use Eq. 41.6 to find the fraction remaining.

$$N = N_0 e^{-\lambda t} \quad \rightarrow \quad \frac{N}{N_0} = e^{-\lambda t} = e^{-\left[\frac{(\ln 2)(2.0\,\mathrm{yr})(12\,\mathrm{mo/yr})}{9\,\mathrm{mo}}\right]} = 0.158 \approx \boxed{0.16}$$

42. The activity at a given time is given by Eq. 41-7b. The half-life is found in Appendix F.

$$\left|\frac{dN}{dt}\right| = \lambda N = \frac{\ln 2}{T_{1/2}}N = \frac{\ln 2}{(5730\,\mathrm{yr})(3.16\times10^{7}\,\mathrm{s/yr})}(8.1\times10^{20}\,\mathrm{nuclei}) = \boxed{3.1\times10^{9}\,\mathrm{decays/s}}$$

43. Every half-life, the sample is multiplied by one-half.

$$\frac{N}{N_0} = \left(\tfrac{1}{2}\right)^{n} = \left(\tfrac{1}{2}\right)^{6} = \boxed{0.015625}$$

44. The activity of a sample is given by Eq. 41-7a. There are two different decay constants involved. Note that Appendix F gives half-lives, not activities.

$$\lambda_{\mathrm{I}}N_{\mathrm{I}} = \lambda_{\mathrm{Co}}N_{\mathrm{Co}} \quad \rightarrow \quad \lambda_{\mathrm{I}}N_0 e^{-\lambda_{\mathrm{I}}t} = \lambda_{\mathrm{Co}}N_0 e^{-\lambda_{\mathrm{Co}}t} \quad \rightarrow \quad \frac{\lambda_{\mathrm{I}}}{\lambda_{\mathrm{Co}}} = e^{(\lambda_{\mathrm{I}}-\lambda_{\mathrm{Co}})t} \quad \rightarrow$$

$$t = \frac{\ln\left(\lambda_{\mathrm{I}}/\lambda_{\mathrm{Co}}\right)}{\lambda_{\mathrm{I}}-\lambda_{\mathrm{Co}}} = \frac{\ln\left(\dfrac{T_{\mathrm{Co}}}{T_{\mathrm{I}}}\right)}{\dfrac{\ln 2}{T_{\mathrm{I}}} - \dfrac{\ln 2}{T_{\mathrm{Co}}}} = \frac{\ln\left[\dfrac{(5.2710\,\mathrm{y})(365.25\,\mathrm{d/y})}{(8.0233\,\mathrm{d})}\right]}{\ln 2\left[\dfrac{1}{(8.0233\,\mathrm{d})} - \dfrac{1}{(5.2710\,\mathrm{y})(365.25\,\mathrm{d/y})}\right]} = \boxed{63.703\,\mathrm{d}}$$

45. We find the number of nuclei from the activity of the sample and the half-life.

$$\left|\frac{dN}{dt}\right| = \lambda N = \frac{\ln 2}{T_{1/2}} N \quad \rightarrow$$

$$N = \frac{T_{1/2}}{\ln 2}\left|\frac{dN}{dt}\right| = \frac{\left(4.468\times10^{9}\,\text{yr}\right)\left(3.156\times10^{7}\,\text{s/yr}\right)}{\ln 2}\left(340\,\text{decays/s}\right) = \boxed{6.9\times10^{19}\,\text{nuclei}}$$

46. Each α emission decreases the mass number by 4 and the atomic number by 2. The mass number changes from 235 to 207, which is a change of 28. Thus there must be $\boxed{7\,\alpha\text{ particles}}$ emitted. With the 7 α emissions, the atomic number would have changed from 92 to 78. Each β^- emission increases the atomic number by 1, so to have a final atomic number of 82, there must be $\boxed{4\,\beta^-\text{ particles}}$ emitted.

47. We need both the decay constant and the initial number of nuclei.

$$\lambda = \frac{\ln 2}{T_{1/2}} = \frac{\ln 2}{\left(8.0233\,\text{days}\right)\left(24\,\text{h/day}\right)\left(3600\,\text{s/h}\right)} = 9.99905\times10^{-7}\,\text{s}^{-1}$$

$$N_0 = \left[\frac{\left(782\times10^{-6}\,\text{g}\right)}{\left(130.906\,\text{g/mol}\right)}\right]\left(6.02\times10^{23}\,\text{atoms/mol}\right) = 3.596\times10^{18}\,\text{nuclei.}$$

(*a*) We Eq. 41-7b to evaluate the initial activity.

$$\left|\frac{dN}{dt}\right|_0 = \left(9.99905\times10^{-7}\,\text{s}^{-1}\right)\left(3.596\times10^{18}\right) = 3.5957\times10^{12}\,\text{decays/s} \approx \boxed{3.60\times10^{12}\,\text{decays/s}}$$

(*b*) We evaluate Eq. 41-7c at $t = 1.0\,\text{h}$.

$$\left|\frac{dN}{dt}\right| = \left|\frac{dN}{dt}\right|_0 e^{-\lambda t} = \left(3.5957\times10^{12}\,\text{decays/s}\right)e^{-\left(9.99905\times10^{-7}\,\text{s}^{-1}\right)(3600\,\text{s})}$$

$$\approx \boxed{3.58\times10^{12}\,\text{decays/s}}$$

(*c*) We evaluate Eq. 41-7c at *t* = 4 months. We use a time of 1/3 year for the 4 months.

$$\left|\frac{dN}{dt}\right| = \left|\frac{dN}{dt}\right|_0 e^{-\lambda t} = \left(3.5957\times10^{12}\,\text{decays/s}\right)e^{-\left(9.99905\times10^{-7}\,\text{s}^{-1}\right)(0.333\,\text{yr})\left(3.156\times10^{7}\,\text{s/yr}\right)}$$

$$\approx \boxed{9.72\times10^{7}\,\text{decays/s}}$$

48. We will use the decay constant frequently, so we calculate it here.

$$\lambda = \frac{\ln 2}{T_{1/2}} = \frac{\ln 2}{30.8\,\text{s}} = 0.022505\,\text{s}^{-1}$$

(*a*) We find the initial number of nuclei from the atomic mass.

$$N_0 = \frac{\left(7.8\times10^{-6}\,\text{g}\right)}{\left(124\,\text{g/mol}\right)}\left(6.02\times10^{23}\,\text{atoms/mol}\right) = 3.787\times10^{16} \approx \boxed{3.8\times10^{16}\,\text{nuclei.}}$$

(*b*) Evaluate Eq. 41-6 at $t = 2.6\,\text{min}$.

$$N = N_0 e^{-\lambda t} = \left(3.787\times10^{16}\right)e^{-\left(0.022505\,\text{s}^{-1}\right)(2.6\,\text{min})(60\,\text{s/min})} = 1.131\times10^{15} \approx \boxed{1.1\times10^{15}\,\text{nuclei}}$$

(*c*) The activity is found by Eq. 41-7a.

$$\lambda N = \left(0.022505\,\text{s}^{-1}\right)\left(1.131\times10^{15}\right) = 2.545\times10^{13} \approx \boxed{2.5\times10^{13}\,\text{decays/s}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*d*) We find the time from Eq. 41-7a.

$$\lambda N = \lambda N_0 e^{-\lambda t} \quad \rightarrow$$

$$t = -\frac{\ln\left(\frac{\lambda N}{\lambda N_0}\right)}{\lambda} = -\frac{\ln\left[\frac{1\text{decay/s}}{\left(0.022505\text{s}^{-1}\right)\left(3.787\times10^{16}\right)\text{decay/s}}\right]}{0.022505\text{s}^{-1}} = 1528\text{s} = 25.46\text{min} \approx \boxed{25\text{min}}$$

49. We find the mass from the initial decay rate and Eq. 41-7b.

$$\left|\frac{dN}{dt}\right|_0 = \lambda N_0 = \lambda m \frac{6.02\times10^{23}\,\text{nuclei/mole}}{(\text{atomic weight})\,\text{g/mole}} \quad \rightarrow$$

$$m = \left|\frac{dN}{dt}\right|_0 \frac{1}{\lambda}\frac{(\text{atomic weight})}{\left(6.02\times10^{23}\right)} = \left|\frac{dN}{dt}\right|_0 \frac{T_{1/2}}{\ln 2}\frac{(\text{atomic weight})}{\left(6.02\times10^{23}\right)}$$

$$= \left(2.0\times10^5\text{s}^{-1}\right)\frac{\left(1.265\times10^9\,\text{yr}\right)\left(3.156\times10^7\,\text{s/yr}\right)}{(\ln 2)}\frac{(39.963998\,\text{g})}{\left(6.02\times10^{23}\right)} = \boxed{0.76\,\text{g}}$$

50. The number of nuclei is found from the mass and the atomic weight. The activity is then found from number of nuclei and the half-life, using Eq. 41-7b.

$$\left|\frac{dN}{dt}\right| = \lambda N = \frac{\ln 2}{T_{1/2}}N = \frac{\ln 2}{1.23\times10^6\text{s}}\left[\frac{\left(8.7\times10^{-6}\text{g}\right)}{(31.974\,\text{g/mol})}\right]\left(6.02\times10^{23}\,\text{atoms/mol}\right) = 9.2\times10^{10}\,\text{decays/s}$$

51. We find the mass from the initial decay rate and Eq. 41-7b.

$$\left|\frac{dN}{dt}\right|_0 = \lambda N_0 = \lambda m \frac{6.02\times10^{23}\,\text{nuclei/mole}}{(\text{atomic weight})\,\text{g/mole}} \quad \rightarrow$$

$$m = \left|\frac{dN}{dt}\right|_0 \frac{1}{\lambda}\frac{(\text{atomic weight})}{\left(6.02\times10^{23}\right)} = \left|\frac{dN}{dt}\right|_0 \frac{T_{1/2}}{\ln 2}\frac{(\text{atomic weight})}{\left(6.02\times10^{23}\right)}$$

$$= \left(3.65\times10^4\text{s}^{-1}\right)\frac{(87.32\text{d})(86{,}400\text{s/d})}{(\ln 2)}\frac{(34.969032\,\text{g})}{\left(6.02\times10^{23}\right)} = \boxed{2.31\times10^{-11}\text{g}}$$

52. (*a*) The decay constant is found from Eq. 41-8.

$$\lambda = \frac{\ln 2}{T_{1/2}} = \frac{\ln 2}{\left(1.59\times10^5\,\text{yr}\right)\left(3.156\times10^7\,\text{s/yr}\right)} = \boxed{1.38\times10^{-13}\,\text{s}^{-1}}$$

(*b*) The activity is the decay constant times the number of nuclei.

$$\lambda N = \left(1.38\times10^{-13}\,\text{s}^{-1}\right)\left(5.50\times10^{18}\right) = 7.59\times10^5\,\text{decays/s}\left(\frac{60\text{s}}{1\text{min}}\right) = \boxed{4.55\times10^7\,\text{decays/min.}}$$

53. We use Eq. 41-7c.

$$R = R_0 e^{-\lambda t} = R_0 e^{-\frac{\ln 2}{T_{1/2}}t} \quad \rightarrow \quad T_{1/2} = -\frac{\ln 2}{\ln\frac{R}{R_0}}t = -\frac{\ln 2}{\ln\frac{1}{4}}(8.6\text{min}) = \boxed{4.3\text{min}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

54. Because the fraction of atoms that are ${}^{14}_{6}\text{C}$ is so small, we use the atomic weight of ${}^{12}_{6}\text{C}$ to find the number of carbon atoms in the sample. The activity is found from Eq. 41-7a.

$$N = \left[\frac{(385\,\text{g})}{(12\,\text{g/mol})}\right]\left(6.02\times10^{23}\,\text{atoms/mol}\right) = 1.93\times10^{25}\,\text{atoms}$$

$$N_{14} = \left(\frac{1.3}{10^{12}}\right)\left(1.93\times10^{25}\right) = 2.51\times10^{13}\,\text{nuclei}$$

$$\lambda N = \left[\frac{\ln 2}{(5730\,\text{yr})\left(3.156\times10^{7}\,\text{s/yr}\right)}\right]\left(2.51\times10^{13}\right) = \boxed{96\,\text{decays/s}}$$

55. We find the mass from the activity. Note that N_{A} is used to represent Avogadro's number.

$$R = \lambda N = \frac{\ln 2}{T_{1/2}}\frac{mN_{\text{A}}}{A} \quad \rightarrow$$

$$m = \frac{RT_{1/2}A}{N_{\text{A}}\ln 2} = \frac{(370\,\text{decays/s})\left(4.468\times10^{9}\,\text{yr}\right)\left(3.156\times10^{7}\,\text{s/yr}\right)(238.05\,\text{g/mole})}{\left(6.02\times10^{23}\,\text{nuclei/mole}\right)\ln 2} = \boxed{2.98\times10^{-2}\,\text{g}}$$

56. We assume that the elapsed time is much smaller than the half-life, so that can approixmate the decay rate as being constant. We also assume that the ${}^{87}_{38}\text{Sr}$ is stable, and there was none present when the rocks were formed. Thus every atom of ${}^{87}_{37}\text{Rb}$ that decayed is now an atom of ${}^{87}_{38}\text{Sr}$.

$$N_{\text{Sr}} = -\Delta N_{\text{Rb}} = \lambda N_{\text{Rb}}\,\Delta t \quad \rightarrow \quad \Delta t = \frac{N_{\text{Sr}}}{N_{\text{Rb}}}\frac{T_{1/2}}{\ln 2} = (0.0260)\frac{4.75\times10^{10}\,\text{yr}}{\ln 2} = \boxed{1.78\times10^{9}\,\text{yr}}$$

This is $\approx 4\%$ of the half-life, so our original assumption is valid.

57. The activity is given by Eq. 41-7a.

$$0.975\lambda N_0 = \lambda N_0 e^{-\lambda t} \quad \rightarrow \quad \ln 0.975 = -\lambda t = -\frac{\ln 2}{T_{1/2}}t \quad \rightarrow$$

$$T_{1/2} = -\frac{\ln 2}{\ln 0.975}(31.0\,\text{h}) = 848.71\,\text{h}\left(\frac{1\,\text{d}}{24\,\text{h}}\right) = \boxed{35.4\,\text{d}}$$

58. The activity is given by Eq. 41-7a.

(*a*) We use Eq. 41-7c.We find the number of half-lives from

$$R = R_0 e^{-\lambda t} \quad \rightarrow \quad t = -\frac{1}{\lambda}\ln\frac{R}{R_0} = -\frac{T_{1/2}}{\ln 2}\ln\frac{R}{R_0} = -\frac{53\,\text{d}}{\ln 2}\left(\ln\frac{15\,\text{decays/s}}{350\,\text{decays/s}}\right) = 240.85\,\text{d} \approx \boxed{240\,\text{d}}$$

(*b*) We find the mass from the activity. Note that N_{A} is used to represent Avogadro's number.

$$R_0 = \lambda N_0 = \frac{\ln 2}{T_{1/2}}\frac{m_0 N_{\text{A}}}{A} \quad \rightarrow$$

$$m = \frac{R_0 T_{1/2}A}{N_{\text{A}}\ln 2} = \frac{(350\,\text{decays/s})(53\,\text{d})(86{,}400\,\text{s/d})(7.017\,\text{g/mole})}{\left(6.02\times10^{23}\,\text{nuclei/mole}\right)\ln 2} = \boxed{2.7\times10^{-14}\,\text{g}}$$

59. ${}^{232}_{90}\text{Th} \rightarrow \boxed{{}^{228}_{88}\text{Ra}} + {}^{4}_{2}\alpha$; ${}^{228}_{88}\text{Ra} \rightarrow \boxed{{}^{228}_{89}\text{Ac}} + \beta^{-}$; ${}^{228}_{89}\text{Ac} \rightarrow \boxed{{}^{228}_{90}\text{Th}} + \beta^{-}$; ${}^{228}_{90}\text{Th} \rightarrow \boxed{{}^{224}_{88}\text{Ra}} + {}^{4}_{2}\alpha$;
${}^{224}_{88}\text{Ra} \rightarrow \boxed{{}^{220}_{86}\text{Rn}} + {}^{4}_{2}\alpha$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$${}^{235}_{92}\text{U} \rightarrow \boxed{{}^{231}_{90}\text{Th}} + {}^{4}_{2}\alpha \;;\; {}^{231}_{90}\text{Th} \rightarrow \boxed{{}^{231}_{91}\text{Pa}} + \beta^- \;;\; {}^{231}_{91}\text{Pa} \rightarrow \boxed{{}^{227}_{89}\text{Ac}} + {}^{4}_{2}\alpha \;;\; {}^{227}_{89}\text{Ac} \rightarrow \boxed{{}^{227}_{90}\text{Th}} + \beta^- \;;$$
$${}^{227}_{90}\text{Th} \rightarrow \boxed{{}^{223}_{88}\text{Ra}} + {}^{4}_{2}\alpha$$

60. Because the fraction of atoms that are ${}^{14}_{6}\text{C}$ is so small, we use the atomic weight of ${}^{12}_{6}\text{C}$ to find the number of carbon atoms in 85 g. We then use the ratio to find the number of ${}^{14}_{6}\text{C}$ atoms present when the club was made. Finally, we use the activity as given in Eq. 41-7c to find the age of the club.

$$N_{{}^{12}_{6}\text{C}} = \left[\frac{(85\,\text{g})}{(12\,\text{g/mol})}\right]\left(6.02\times10^{23}\,\text{atoms/mol}\right) = 4.264\times10^{24}\,\text{atoms}$$

$$N_{{}^{14}_{6}\text{C}} = \left(1.3\times10^{-12}\right)\left(4.264\times10^{24}\right) = 5.543\times10^{12}\,\text{nuclei}$$

$$\left(\lambda N_{{}^{14}_{6}\text{C}}\right)_{\text{today}} = \left(\lambda N_{{}^{14}_{6}\text{C}}\right)_0 e^{-\lambda t} \;\rightarrow$$

$$t = -\frac{1}{\lambda}\ln\frac{\left(\lambda N_{{}^{14}_{6}\text{C}}\right)_{\text{today}}}{\left(\lambda N_{{}^{14}_{6}\text{C}}\right)_0} = -\frac{T_{1/2}}{\ln 2}\ln\frac{\left(\lambda N_{{}^{14}_{6}\text{C}}\right)_{\text{today}}}{\left(\frac{\ln 2}{T_{1/2}}N_{{}^{14}_{6}\text{C}}\right)_0}$$

$$= -\frac{5730\,\text{yr}}{\ln 2}\ln\frac{(7.0\,\text{decays/s})}{\left[\frac{\ln 2}{(5730\,\text{yr})\left(3.156\times10^{7}\,\text{s/yr}\right)}\left(5.543\times10^{12}\,\text{nuclei}\right)\right]_0} = 9178\,\text{yr} \approx \boxed{9200\,\text{yr}}$$

61. The number of radioactive nuclei decreases exponentially, and every radioactive nucleus that decays becomes a daughter nucleus.

$$N = N_0 e^{-\lambda t}$$

$$N_{\text{D}} = N_0 - N = \boxed{N_0\left(1 - e^{-\lambda t}\right)}$$

62. The activity is given by Eq. 41-7d.

$$R = R_0 e^{-\lambda t} \;\rightarrow\; \lambda = -\frac{\ln\frac{R}{R_0}}{t} = \frac{\ln 2}{T_{1/2}} \;\rightarrow\; T_{1/2} = -\frac{t\ln 2}{\ln\frac{R}{R_0}} = -\frac{(4.00\,\text{h})\ln 2}{\ln 0.01050} = 0.6085\,\text{h} = 36.5\,\text{min}$$

From Appendix F we see that the isotope is $\boxed{{}^{211}_{82}\text{Pb}}$.

63. Because the carbon is being replenished in living trees, we assume that the amount of ${}^{14}_{6}\text{C}$ is constant until the wood is cut, and then it decays. We use Eq. 41-6.

$$N = N_0 e^{-\lambda t} \;\rightarrow\; \lambda = -\frac{\ln\frac{N}{N_0}}{t} = \frac{\ln 2}{T_{1/2}} \;\rightarrow\; t = -\frac{T_{1/2}}{\ln 2}\ln\frac{N}{N_0} = -\frac{(5730\,\text{yr})\ln 0.060}{\ln 2} = \boxed{23{,}000\,\text{yr}}$$

64. (*a*) The mass number is found from the radius, using Eq. 41-1.

$$r = \left(1.2\times10^{-15}\,\text{m}\right)A^{1/3} \;\rightarrow\; A = \left(\frac{r}{1.2\times10^{-15}\,\text{m}}\right)^3 = \left(\frac{5000\,\text{m}}{1.2\times10^{-15}\,\text{m}}\right)^3 = 7.23\times10^{55} \approx \boxed{7\times10^{55}}$$

(*b*) The mass of the neutron star is the mass number times the atomic mass unit conversion in kg.

$$m = A\left(1.66\times10^{-27}\,\text{kg/u}\right) = \left(7.23\times10^{55}\,\text{u}\right)\left(1.66\times10^{-27}\,\text{kg/u}\right) = 1.20\times10^{29}\,\text{kg} \approx \boxed{1\times10^{29}\,\text{kg}}$$

Note that this is about 6% of the mass of the Sun.

(*c*) The acceleration of gravity on the surface of the neutron star is found from Eq. 6-4 applied to the neutron star.

$$g = \frac{Gm}{r^2} = \frac{\left(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(1.20\times10^{29}\,\text{kg}\right)}{\left(5000\,\text{m}\right)^2} = 3.20\times10^{11}\,\text{m/s}^2 \approx \boxed{3\times10^{11}\,\text{m/s}^2}$$

65. Because the tritium in water is being replenished, we assume that the amount is constant until the wine is made, and then it decays. We use Eq. 41-6.

$$N = N_0e^{-\lambda t} \;\rightarrow\; \lambda = -\frac{\ln\dfrac{N}{N_0}}{t} = \frac{\ln 2}{T_{1/2}} \;\rightarrow\; t = -\frac{T_{1/2}}{\ln 2}\ln\frac{N}{N_0} = -\frac{(12.3\,\text{yr})\ln 0.10}{\ln 2} = \boxed{41\,\text{yr}}$$

66. We assume a mass of 70 kg of water, and find the number of protons, given that there are 10 protons in a water molecule.

$$N_{\text{protons}} = \left[\frac{\left(70\times10^3\,\text{g water}\right)}{\left(18\,\text{g water/mol water}\right)}\right]\left(6.02\times10^{23}\,\text{molecules water/mol water}\right)\left(\frac{10\,\text{protons}}{\text{water molecule}}\right)$$

$$= 2.34\times10^{28}\,\text{protons}$$

We assume that the time is much less than the half-life so that the rate of decay is constant.

$$\frac{\Delta N}{\Delta t} = \lambda N = \left(\frac{\ln 2}{T_{1/2}}\right)N \;\rightarrow\; \Delta t = \frac{\Delta N}{N}\left(\frac{T_{1/2}}{\ln 2}\right) = \frac{1\text{ proton}}{2.34\times10^{28}\,\text{protons}}\left(\frac{10^{33}\,\text{yr}}{\ln 2}\right) = \boxed{60{,}000\,\text{yr}}$$

This is almost 1000 times a normal life expectancy.

67. Consider the reaction $\text{n} \rightarrow \text{p} + \text{e}^- + \bar{\nu}$. The neutron, proton, and electron are all spin $\frac{1}{2}$ particles. If the proton and neutron spins are aligned (both are $\frac{1}{2}$, for example), then the electron and neutrino spins must cancel. Since the electron is spin $\frac{1}{2}$, the neutrino must also be spin $\frac{1}{2}$ in this case.

The other possibility is if the proton and neutron spins are opposite of each other. Consider the case of the neutron having spin $\frac{1}{2}$ and the proton having spin $-\frac{1}{2}$. If the electron has spin $\frac{1}{2}$, then the spins of the electron and proton cancel, and the neutrino must have spin $\frac{1}{2}$ for angular momentum to be conserved. If the electron has spin $-\frac{1}{2}$, then the spin of the neutrino must be $\frac{3}{2}$ for angular momentum to be conserved.

A similar argument could be made for positron emission, with $\text{p} \rightarrow \text{n} + \text{e}^+ + \nu$.

68. We assume that all of the kinetic energy of the alpha particle becomes electrostatic potential energy at the distance of closest approach. Note that the distance found is the distance from the center of the alpha to the center of the gold nucleus.

$$K_\text{i} + U_\text{i} = K_\text{f} + U_\text{f} \quad \rightarrow \quad K_\alpha + 0 = 0 + \frac{1}{4\pi\varepsilon_0}\frac{q_\alpha q_\text{Au}}{r} \quad \rightarrow$$

$$r = \frac{1}{4\pi\varepsilon_0}\frac{q_\alpha q_\text{Au}}{K_\alpha} = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(2)(79)\left(1.60\times10^{-19}\,\text{C}\right)^2}{(7.7\text{MeV})\left(1.60\times10^{-13}\,\text{J/MeV}\right)} = 2.951\times10^{-14}\,\text{m}$$

$$\approx \boxed{3.0\times10^{-14}\,\text{m}}$$

We use Eq. 41-1 to compare to the size of the gold nucleus.

$$\frac{r_\text{approach}}{r_\text{Au}} = \frac{2.951\times10^{-14}\,\text{m}}{197^{1/3}\left(1.2\times10^{-15}\,\text{m}\right)} = 4.2$$

So the distance of approach is about $\boxed{4.2\times}$ the radius of the gold nucleus.

69. We find the number of half-lives from the change in activity.

$$\frac{\left|\frac{dN}{dt}\right|}{\left|\frac{dN}{dt}\right|_0} = \left(\tfrac{1}{2}\right)^n = 0.0100 \quad \rightarrow \quad n = \frac{\ln 0.0100}{\ln\frac{1}{2}} = \boxed{6.64\text{ half-lives}}$$

70. We find the mass from the activity. Note that N_A is used to represent Avogadro's number.

$$R = \lambda N = \frac{\ln 2}{T_{1/2}}\frac{m_{40}N_\text{A}}{A} \quad \rightarrow$$

$$m_{40} = \frac{RT_{1/2}A}{N_\text{A}\ln 2} = \frac{(45\,\text{decays/s})\left(1.265\times10^9\,\text{yr}\right)\left(3.156\times10^7\,\text{s/yr}\right)(39.964\,\text{g/mole})}{\left(6.02\times10^{23}\,\text{nuclei/mole}\right)\ln 2} = 1.721\times10^{-4}\,\text{g}$$

$$\approx \boxed{1.7\times10^{-4}\,\text{g}}$$

We find the number of ${}^{39}_{19}\text{K}$ atoms from the number of ${}^{40}_{19}\text{K}$ atoms and the abundance given in Appendix F. That is then used to find the mass of ${}^{39}_{19}\text{K}$.

$$R = \lambda N_{40} \quad \rightarrow \quad N_{40} = \frac{R}{\lambda} = \frac{RT_{1/2}}{\ln 2} \;;\; N_{40} = 0.000117N_K \;;\; N_{39} = 0.93258N_K = \frac{0.93258}{0.000117}N_{40}$$

$$m_{39} = N_{39}\frac{A}{N_\text{A}} = \frac{0.93258}{0.000117}N_{40}\frac{A}{N_\text{A}} = \frac{0.93258}{0.000117}\frac{RT_{1/2}}{\ln 2}\frac{A}{N_\text{A}}$$

$$= \left(\frac{0.93258}{0.000117}\right)\frac{(45\,\text{decays/s})\left(1.265\times10^9\,\text{yr}\right)\left(3.156\times10^7\,\text{s/yr}\right)}{\ln 2}\frac{(38.964\,\text{g/mole})}{\left(6.02\times10^{23}\,\text{nuclei/mole}\right)}$$

$$= \boxed{1.3\text{g}}$$

71. (*a*) If the initial nucleus is at rest when it decays, momentum conservation says that the magnitude of the momentum of the alpha particle will be equal to the magnitude of the momentum of the daughter particle. We use that to calculate the (non-relativistic) kinetic energy of the daughter particle. The mass of each particle is essentially equal to its atomic mass number, in atomic mass units.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$p_\alpha = p_\mathrm{D} \;\; ; \;\; K_\mathrm{D} = \frac{p_\mathrm{D}^2}{2m_\mathrm{D}} = \frac{p_\alpha^2}{2m_\mathrm{D}} = \frac{2m_\alpha K_\alpha}{2m_\mathrm{D}} = \frac{m_\alpha}{m_\mathrm{D}} K_\alpha = \frac{A_\alpha}{A_\mathrm{D}} K_\alpha = \frac{4}{A_\mathrm{D}} K_\alpha$$

$$\frac{K_\mathrm{D}}{K_\alpha + K_\mathrm{D}} = \frac{\frac{4}{A_\mathrm{D}} K_\alpha}{\left[K_\alpha + \frac{4}{A_\mathrm{D}} K_\alpha \right]} = \frac{K_\alpha}{\left[\frac{A_\mathrm{D}}{4} K_\alpha + K_\alpha \right]} = \boxed{\frac{1}{1 + \frac{1}{4} A_\mathrm{D}}}$$

(*b*) We specifically consider the decay of $^{226}_{88}\mathrm{Ra}$. The daughter has $A_\mathrm{D} = 222$.

$$\frac{K_\mathrm{D}}{K_\alpha + K_\mathrm{D}} = \frac{1}{1 + \frac{1}{4} A_\mathrm{D}} = \frac{1}{1 + \frac{1}{4}(222)} = 0.017699 \approx 1.8\%$$

Thus the alpha particle carries away $1 - 0.018 = 0.982 = \boxed{98.2\%}$.

72. We see from the periodic chart that Sr is in the same column as calcium. If strontium is ingested, the body may treat it chemically as if it were calcium, which means it might be stored by the body in bones. We use Eq. 41-6 to find the time to reach a 1% level.

$$N = N_0 e^{-\lambda t} \;\; \rightarrow \;\; \lambda = -\frac{\ln \frac{N}{N_0}}{t} = \frac{\ln 2}{T_{1/2}} \;\; \rightarrow$$

$$t = -\frac{T_{1/2}}{\ln 2} \ln \frac{N}{N_0} = -\frac{(29\,\mathrm{yr}) \ln 0.010}{\ln 2} = 192.67\,\mathrm{yr} \approx \boxed{190\,\mathrm{yr}}$$

The decay reactions are as follows. We assume the daughter undergoes beta decay.

$$\boxed{^{90}_{38}\mathrm{Sr} \rightarrow {}^{90}_{39}\mathrm{Y} + {}^{0}_{-1}\mathrm{e} + \overline{\nu} \;\; ; \;\; {}^{90}_{39}\mathrm{Y} \rightarrow {}^{90}_{40}\mathrm{Zr} + {}^{0}_{-1}\mathrm{e} + \overline{\nu}}$$

73. We take the momentum of the nucleon to be equal to the uncertainty in the momentum of the nucleon, as given by the uncertainty principle. The uncertainty in position is estimate as the radius of the nucleus. With that momentum, we calculate the kinetic energy, using a classical formula.

$$\Delta p \Delta x \approx \hbar \;\; \rightarrow \;\; p \approx \Delta p \approx \frac{\hbar}{\Delta x} = \frac{\hbar}{r}$$

$$K = \frac{p^2}{2m} = \frac{\hbar^2}{2mr^2} = \frac{\left((1.055 \times 10^{-34}\,\mathrm{J \cdot s}) \right)^2}{2(1.67 \times 10^{-27}\,\mathrm{kg}) \left[(56^{1/3})(1.2 \times 10^{-15}\,\mathrm{m}) \right]^2 (1.60 \times 10^{-13}\,\mathrm{J/MeV})}$$

$$= 0.988\,\mathrm{MeV} \approx \boxed{1\,\mathrm{MeV}}$$

74. (*a*) The reaction is $^{236}_{92}\mathrm{U} \rightarrow {}^{232}_{90}\mathrm{Th} + {}^{4}_{2}\mathrm{He}$. If we assume the uranium nucleus is initially at rest, then the magnitude of the momenta of the two products must be the same. The kinetic energy available to the products is the *Q*-value of the reaction. We use the non-relativistic relationship that $p^2 = 2mK$.

$$p_\mathrm{He} = p_\mathrm{Th} \;\; ; \;\; K_\mathrm{Th} = \frac{p_\mathrm{Th}^2}{2m_\mathrm{Th}} = \frac{p_\mathrm{He}^2}{2m_\mathrm{Th}} = \frac{2m_\mathrm{He} K_\mathrm{He}}{2m_\mathrm{Th}} = \frac{m_\mathrm{He}}{m_\mathrm{Th}} K_\mathrm{He}$$

$$Q = K_\mathrm{Th} + K_\mathrm{He} = \left(\frac{m_\mathrm{He}}{m_\mathrm{Th}} + 1 \right) K_\mathrm{He} \;\; \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$K_{\text{He}} = \left(\frac{m_{\text{Th}}}{m_{\text{He}} + m_{\text{Th}}}\right) Q = \left(\frac{m_{\text{Th}}}{m_{\text{He}} + m_{\text{Th}}}\right)\left[m_{\text{U}} - m_{\text{Th}} - m_{\text{He}}\right]c^2$$

$$= \left(\frac{232.038055\,\text{u}}{4.002603\,\text{u} + 232.038055\,\text{u}}\right)\left[236.045568\,\text{u} - 232.038055\,\text{u} - 4.002603\,\text{u}\right]c^2$$

$$= 0.004827\,\text{u}\left(931.5\,\text{MeV}/\text{u}c^2\right) = \boxed{4.496\,\text{MeV}}$$

(*b*) We use Eq. 41-1 to estimate the radii.

$$r_{\text{He}} = \left(1.2\times10^{-15}\,\text{m}\right)(4)^{1/3} = 1.905\times10^{-15}\,\text{m} \approx \boxed{1.9\times10^{-15}\,\text{m}}$$

$$r_{\text{Th}} = \left(1.2\times10^{-15}\,\text{m}\right)(232)^{1/3} = 7.374\times10^{-15}\,\text{m} \approx \boxed{7.4\times10^{-15}\,\text{m}}$$

(*c*) The maximum height of the Coulomb barrier will correspond to the alpha particle and the thorium nucleus being separated by the sum of their radii. We use Eq. 23-10.

$$U = \frac{1}{4\pi\varepsilon_0}\frac{q_{\text{He}}q_{\text{Th}}}{r_{\text{A}}} = \frac{1}{4\pi\varepsilon_0}\frac{q_{\text{He}}q_{\text{Th}}}{\left(r_{\text{He}} + r_{\text{Th}}\right)}$$

$$= \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(2)(90)\left(1.60\times10^{-19}\,\text{C}\right)^2}{\left(4^{1/3} + 232^{1/3}\right)\left(1.2\times10^{-15}\,\text{m}\right)\left(1.60\times10^{-13}\,\text{J/MeV}\right)}$$

$$= 27.898\,\text{MeV} \approx \boxed{28\,\text{MeV}}$$

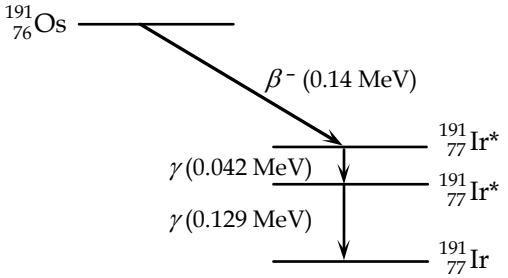
(*d*) At position "A", the product particles are separated by the sum of their radii, about 9.3 fm. At position "B", the alpha particle will have a potential energy equal to its final kinetic energy, 4.496 MeV. Use Eq. 23-10 to solve for the separation distance at position "B".

$$U_{\text{B}} = \frac{1}{4\pi\varepsilon_0}\frac{q_{\text{He}}q_{\text{Th}}}{r_{\text{B}}} \quad \rightarrow$$

$$r_{\text{B}} = \frac{1}{4\pi\varepsilon_0}\frac{q_{\text{He}}q_{\text{Th}}}{U_{\text{B}}} = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(2)(90)\left(1.60\times10^{-19}\,\text{C}\right)^2}{\left(4.496\,\text{MeV}\right)\left(1.60\times10^{-13}\,\text{J/MeV}\right)}$$

$$= 57.57\times10^{-15}\,\text{m}$$

$$r_{\text{B}} - r_{\text{A}} = 57.6\,\text{fm} - 9.3\,\text{fm} = \boxed{48.3\,\text{fm}}$$



Note that this is a center-to-center distance.

75. (*a*) We find the daughter nucleus by balancing the mass and charge numbers:

$$Z(X) = Z(\text{Os}) - Z\left(\text{e}^-\right) = 76 - (-1) = 77$$

$$A(X) = A(\text{Os}) - A\left(\text{e}^-\right) = 191 - 0 = 191$$

The daughter nucleus is $\boxed{{}^{191}_{77}\text{Ir}}$.

(*b*) See the included diagram.

(*c*) Because there is only one β energy, the β decay must be to the higher excited state.

76. The activity is the decay constant times the number of nuclei, as given by Eq. 41-7a.

(*a*) We calculate the activity for $^{131}_{53}\text{I}$.

$$R = \lambda N = \frac{\ln 2}{T_{1/2}}N = \frac{\ln 2}{(8.02\,\text{d})(86{,}400\,\text{s/d})}\left(\frac{1.0\,\text{g}}{130.906\,\text{g/mol}}\right)\left(6.02\times10^{23}\ \text{nuclei/mol}\right)$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= \boxed{4.6\times10^{15}\ \text{decays/s}}$$

(*b*) We calculate the activity for $^{238}_{92}\text{U}$.

$$R = \frac{\ln 2}{T_{1/2}}N = \frac{\ln 2}{(4.47\times10^{9}\ \text{yr})(3.156\times10^{7}\ \text{s/yr})}\left(\frac{1.0\,\text{g}}{238.051\,\text{g/mol}}\right)(6.02\times10^{23}\ \text{nuclei/mol})$$

$$= \boxed{1.2\times10^{4}\ \text{decays/s}}$$

77. From Figure 30–1, we see that the average binding energy per nucleon at $A = 63$ is ~8.6 MeV. We use the mass average atomic weight as the average number of nucleons for the two stable isotopes of copper. That gives a binding energy of $(63.546)(8.6\,\text{MeV}) = 546.5\,\text{MeV} \approx \boxed{550\,\text{MeV}}$.

The number of atoms in a penny is found from the atomic weight.

$$N = \frac{(3.0\,\text{g})}{(63.546\,\text{g/mol})}(6.02\times10^{23}\ \text{atoms/mol}) = 2.842\times10^{22}\ \text{atoms}$$

Thus the total energy needed is the product of the number of atoms times the binding energy.

$$(2.842\times10^{22}\ \text{atoms})(546.5\,\text{MeV/atom})(1.60\times10^{-13}\ \text{J/MeV}) = \boxed{2.5\times10^{12}\ \text{J}}$$

78. (*a*) $\Delta(^{4}_{2}\text{He}) = m(^{4}_{2}\text{He}) - A(^{4}_{2}\text{He}) = 4.002603\,\text{u} - 4 = \boxed{0.002603\,\text{u}}$

$$= (0.002603\,\text{u})(931.5\,\text{MeV/u}c^2) = \boxed{2.425\,\text{Mev}/c^2}$$

(*b*) $\Delta(^{12}_{6}\text{C}) = m(^{12}_{6}\text{C}) - A(^{12}_{6}\text{C}) = 12.000000\,\text{u} - 12 = \boxed{0}$

(*c*) $\Delta(^{86}_{38}\text{Sr}) = m(^{86}_{38}\text{Sr}) - A(^{86}_{38}\text{Sr}) = 85.909260\,\text{u} - 86 = \boxed{-0.090740\,\text{u}}$

$$= (-0.090740\,\text{u})(931.5\,\text{MeV/u}c^2) = \boxed{-84.52\,\text{MeV}/c^2}$$

(*d*) $\Delta(^{235}_{92}\text{U}) = m(^{235}_{92}\text{U}) - A(^{235}_{92}\text{U}) = 235.043930\,\text{u} - 235 = \boxed{0.043930\,\text{u}}$

$$= (0.043930\,\text{u})(931.5\,\text{MeV/u}c^2) = \boxed{40.92\,\text{MeV}/c^2}$$

(*e*) From the Appendix we see that

$\boxed{\begin{array}{l}\Delta \ge 0 \text{ for } 0 \le Z \le 8 \text{ and } Z \ge 85;\\ \Delta < 0 \text{ for } 9 \le Z \le 84.\end{array}}$ $\boxed{\begin{array}{l}\Delta \ge 0 \text{ for } 0 \le A \le 15 \text{ and } A > 214;\\ \Delta < 0 \text{ for } 16 \le A \le 214.\end{array}}$

79. The reaction is $^{1}_{1}\text{H} + ^{1}_{0}\text{n} \rightarrow ^{2}_{1}\text{H}$. If we assume the initial kinetic energies are small, then the energy of the gamma is the *Q*-value of the reaction.

$$Q = \left[m(^{1}_{1}\text{He}) + m(^{1}_{0}\text{n}) - m(^{2}_{1}\text{He})\right]c^2$$

$$= \left[(1.007825\,\text{u}) + (1.008665\,\text{u}) - (2.014082\,\text{u})\right]c^2\,(931.5\,\text{MeV/u}c^2) = \boxed{2.243\,\text{MeV}}$$

80. (*a*) We use the definition of the mean life given in the problem. We use a definite integral formula from Appendix B-5.

$$\tau = \frac{\int_0^\infty tN(t)\,dt}{\int_0^\infty N(t)\,dt} = \frac{\int_0^\infty tN_0e^{-\lambda t}\,dt}{\int_0^\infty N_0e^{-\lambda t}\,dt} = \frac{\int_0^\infty te^{-\lambda t}\,dt}{\int_0^\infty e^{-\lambda t}\,dt} = \frac{\frac{1}{\lambda^2}}{-\frac{1}{\lambda}e^{-\lambda t}\Big|_0^\infty} = \frac{\frac{1}{\lambda^2}}{\frac{1}{\lambda}} = \boxed{\frac{1}{\lambda}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We evaluate at time $t = \tau = \dfrac{1}{\lambda}$.

$$\frac{N(t=\tau)}{N(t=0)} = \frac{N_0 e^{-\lambda\tau}}{N_0 e^{-0}} = e^{-\frac{\lambda}{\lambda}} = e^{-1} = \boxed{0.368}$$

81. (*a*) The usual fraction of ${}^{14}_{6}\text{C}$ is 1.3×10^{-12}. Because the fraction of atoms that are ${}^{14}_{6}\text{C}$ is so small, we use the atomic weight of ${}^{12}_{6}\text{C}$ to find the number of carbon atoms in 72 g. We use Eq. 41-6 to find the time.

$$N_{12} = \left(\frac{72\,\text{g}}{12\,\text{g/mol}}\right)\left(6.02\times10^{23}\,\text{atoms/mol}\right) = 3.612\times10^{24}\,\text{atoms}$$

$$N_{14} = \left(3.612\times10^{24}\,\text{atoms}\right)\left(1.3\times10^{-12}\right) = 4.6956\times10^{12}\,\text{atoms}$$

$$N = N_0 e^{-\lambda t} \;\rightarrow\; t = -\frac{1}{\lambda}\ln\frac{N}{N_0} = -\frac{T_{1/2}}{\ln 2}\ln\frac{N}{N_0} = -\frac{(5730\,\text{yr})}{\ln 2}\ln\frac{1}{4.6956\times10^{12}} = \boxed{2.4\times10^{5}\,\text{yr}}$$

(*b*) We do a similar calculation for an initial mass of 270 grams.

$$N_{14} = \left(\frac{270\,\text{g}}{12\,\text{g/mol}}\right)\left(6.02\times10^{23}\,\text{atoms/mol}\right)\left(1.3\times10^{-12}\right) = 1.761\times10^{13}\,\text{atoms}$$

$$N = N_0 e^{-\lambda t} \;\rightarrow\; t = -\frac{1}{\lambda}\ln\frac{N}{N_0} = -\frac{T_{1/2}}{\ln 2}\ln\frac{N}{N_0} = -\frac{(5730\,\text{yr})}{\ln 2}\ln\frac{1}{1.761\times10^{13}} = \boxed{2.5\times10^{5}\,\text{yr}}$$

This shows that, for times on the order of 10^5 yr, the sample amount has fairly little effect on the age determined. Thus, times of this magnitude are not accurately measured by carbon dating.

82. (*a*) This reaction would turn the protons and electrons in atoms into neutrons. This would eliminate chemical reactions, and thus eliminate life as we know it.

(*b*) We assume that there is no kinetic energy brought into the reaction, and solve for the increase of mass necessary to make the reaction energetically possible. For calculating energies, we write the reaction as ${}^{1}_{1}\text{H} \;\rightarrow\; {}^{1}_{0}\text{n} + \nu$, and we assume the neutrino has no mass or kinetic energy.

$$Q = \left[m\left({}^{1}_{1}\text{H}\right) - m\left({}^{1}_{0}\text{n}\right)\right]c^2 = \left[(1.007825\,\text{u}) - (1.008665\,\text{u})\right]c^2\left(931.5\,\text{MeV/uc}^2\right)$$
$$= -0.782\,\text{MeV}$$

This is the amount that the proton would have to increase in order to make this energetically possible. We find the percentage change.

$$\left(\frac{\Delta m}{m}\right)(100) = \left[\frac{\left(0.782\,\text{MeV}/c^2\right)}{\left(938.27\,\text{MeV}/c^2\right)}\right](100) = \boxed{0.083\%}$$

83. We assume the particles are not relativistic, so that $p = \sqrt{2mK}$. The radius is given in Example 27-7 as $r = \dfrac{mv}{qB}$. Set the radii of the two particles equal. Note that the charge of the alpha particle is twice that of the electron (in absolute value). We also use the "bare" alpha particle mass, subtracting the two electrons from the helium atomic mass.

$$\frac{m_\alpha v_\alpha}{2eB} = \frac{m_\beta v_\beta}{eB} \;\rightarrow\; m_\alpha v_\alpha = 2m_\beta v_\beta \;\rightarrow\; p_\alpha = 2p_\beta$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{K_\alpha}{K_\beta}=\frac{\dfrac{p_\alpha^2}{2m_\alpha}}{\dfrac{p_\beta^2}{2m_\beta}}=\frac{\dfrac{4p_\beta^2}{2m_\alpha}}{\dfrac{p_\beta^2}{2m_\beta}}=\frac{4m_\beta}{m_\alpha}=\frac{4(0.000549\,\text{u})}{4.002603\,\text{u}-2(0.000549\,\text{u})}=\boxed{5.48\times10^{-4}}$$

84. Natural samarium has an atomic mass of 150.36 grams per mole. We find the number of nuclei in the natural sample, and then take 15% of that to find the number of $^{147}_{62}\text{Sm}$ nuclei. We first find the number of ^{147}Sm nuclei from the mass and proportion information.

$$N_{^{147}_{62}\text{Sm}}=(0.15)N_{\text{natural}}=\frac{(0.15)(1.00\,\text{g})(6.02\times10^{23}\,\text{nuclei/mol})}{150.36\,\text{g/mol}}=6.006\times10^{20}\,\text{nuclei of }{}^{147}_{62}\text{Sm}$$

The activity level is used to calculate the half-life.

$$\text{Activity}=R=\lambda N=\frac{\ln 2}{T_{1/2}}N\ \rightarrow$$

$$T_{1/2}=\frac{\ln 2}{R}N=\frac{\ln 2}{120\,\text{decays/s}}(6.006\times10^{20})=3.469\times10^{18}\,\text{s}\left(\frac{1\,\text{yr}}{3.156\times10^{7}\,\text{s}}\right)=\boxed{1.1\times10^{11}\,\text{yr}}$$

85. Since amounts are not specified, we will assume that "today" there is 0.720 g of $^{235}_{92}\text{U}$ and $100.000-0.720=99.280\,\text{g}$ of $^{238}_{92}\text{U}$. We use Eq. 41-6.

(*a*) Relate the amounts today to the amounts 1.0×10^{9} years ago.

$$N=N_0e^{-\lambda t}\ \rightarrow\ N_0=Ne^{\lambda t}=Ne^{\frac{t}{T_{1/2}}\ln 2}$$

$$(N_0)_{235}=(N_{235})e^{\frac{t}{T_{1/2}}\ln 2}=(0.720\,\text{g})e^{\frac{(1.0\times10^{9}\,\text{yr})}{(7.04\times10^{8}\,\text{yr})}\ln 2}=1.927\,\text{g}$$

$$(N_0)_{238}=(N_{238})e^{\frac{t}{T_{1/2}}\ln 2}=(99.280\,\text{g})e^{\frac{(1.0\times10^{9})}{(4.468\times10^{9})}\ln 2}=115.94\,\text{g}$$

$$N_{0,238}=N_{238}e^{\frac{0.693t}{T_{1/2}}}=(99.28\,\text{g})e^{\frac{0.693(1.0\times10^{9})}{(4.468\times10^{9})}}=115.937\,\text{g}.$$

The percentage of $^{235}_{92}\text{U}$ was $\dfrac{1.927}{1.927+115.94}\times100\%=\boxed{1.63\%}$

(*b*) Relate the amounts today to the amounts 100×10^{6} years from now.

$$N=N_0e^{-\lambda t}\ \rightarrow\ (N_{235})=(N_0)_{235}e^{-\frac{t}{T_{1/2}}\ln 2}=(0.720\,\text{g})e^{-\frac{(100\times10^{6}\,\text{yr})}{(7.04\times10^{8}\,\text{yr})}\ln 2}=0.6525\,\text{g}$$

$$(N_{238})=(N_0)_{238}e^{-\frac{t}{T_{1/2}}\ln 2}=(99.280\,\text{g})e^{-\frac{(100\times10^{6}\,\text{yr})}{(4.468\times10^{9}\,\text{yr})}\ln 2}=97.752\,\text{g}$$

The percentage of $^{235}_{92}\text{U}$ will be $\dfrac{0.6525}{0.6525+97.752}\times100\%=\boxed{0.663\%}$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

86. We determine the number of ${}^{40}_{19}\text{K}$ nuclei in the sample, and then use the half-life to determine the activity.

$$N_{{}^{40}_{19}\text{K}} = (0.000117)N_{{}^{39}_{19}\text{K}} = (0.000117)\frac{(400\times10^{-3}\,\text{g})(6.02\times10^{23}\,\text{atoms/mol})}{38.9637\,\text{g/mol}} = 7.231\times10^{17}$$

$$R = \lambda N = \frac{\ln 2}{T_{1/2}}N = \frac{\ln 2}{1.265\times10^{9}\,\text{yr}}(7.231\times10^{17})\left(\frac{1\,\text{yr}}{3.156\times10^{7}\,\text{s}}\right) = 12.55\,\text{decay/s} \approx \boxed{13\,\text{decay/s}}$$

87. We use Eq. 41-7a to relate the activity to the half-life.

$$\left|\frac{dN}{dt}\right| = R = \lambda N = \frac{\ln 2}{T_{1/2}}N \quad \rightarrow$$

$$T_{1/2} = \frac{\ln 2}{R}N = \frac{\ln 2}{1\,\text{decay/s}}(1.5\times10^{7}\,\text{g})\left(\frac{6.02\times10^{23}\,\text{nuclei}}{152\,\text{g}}\right)\left(\frac{1\,\text{yr}}{3.156\times10^{7}\,\text{s}}\right) = \boxed{1.3\times10^{21}\,\text{yr}}$$

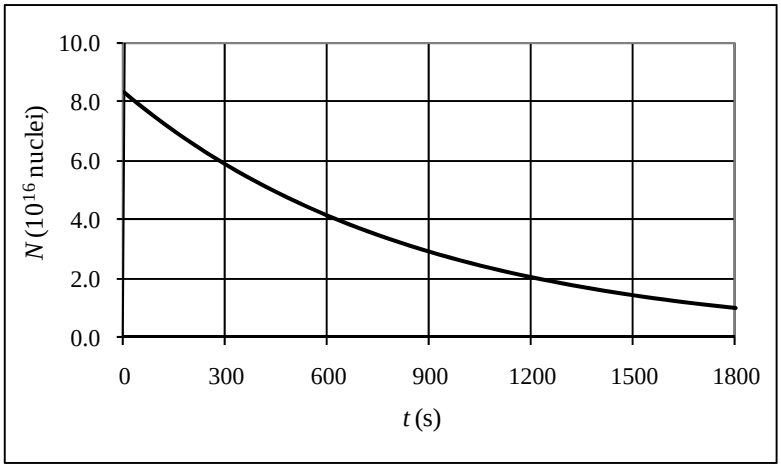
88. The mass number changes only with α decay, and changes by -4. If the mass number is 4*n*, then the new number is $4n-4=4(n-1)=4n'$. There is a similar result for each family, as shown here.

$4n \rightarrow 4n-4=4(n-1)=4n'$

$4n+1 \rightarrow 4n-4+1=4(n-1)+1=4n'+1$

$4n+2 \rightarrow 4n-4+2=4(n-1)+2=4n'+2$

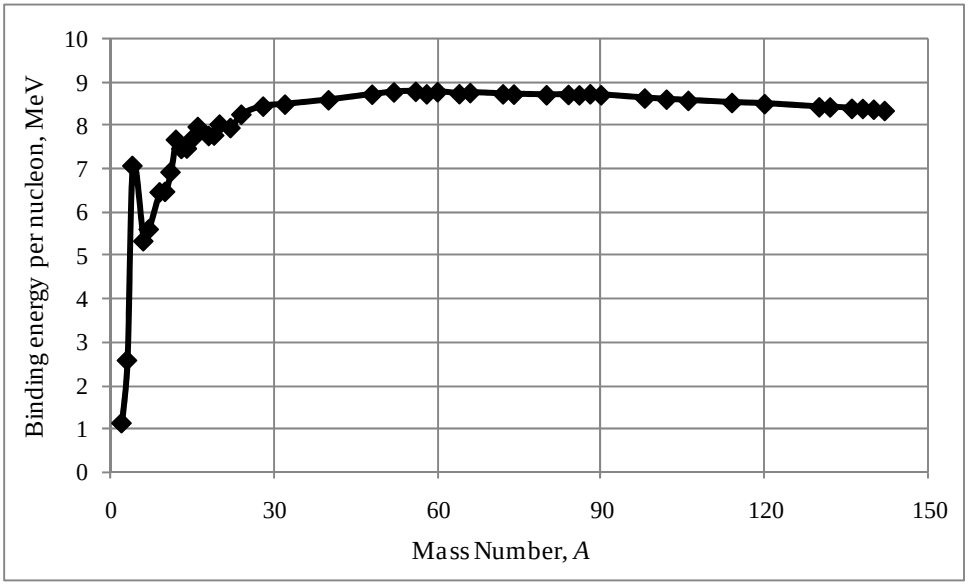
$4n+3 \rightarrow 4n-4+3=4(n-1)+3=4n'+3$



Thus the daughter nuclides are always in the same family.

89. We calculate the initial number of nuclei from the initial mass and the atomic mass.

$$N = (1.80\times10^{-9}\,\text{kg})\frac{1\text{ atom}}{(13.005739\,\text{u})(1.6605\times10^{-27}\,\text{kg})} = 8.3349\times10^{16}\,\text{nuclei} \approx \boxed{8.33\times10^{16}\,\text{nuclei}}$$



See the adjacent graph. From the graph, the half-life is approximately 600 seconds.

CHAPTER 42: Nuclear Energy: Effects and Uses of Radiation

Responses to Questions

1. (*a*) ${}^{138}_{56}\mathrm{Ba}$; (*b*) p or ${}^{1}_{1}\mathrm{H}$; (*c*) γ ; (*d*) ${}^{199}_{80}\mathrm{Hg}$

2. ${}^{32}_{16}\mathrm{S}$

3. ${}^{20}_{10}\mathrm{Ne}$

4. Neutrons have no net charge, and therefore do not have to overcome the Coulomb barrier (Coulomb repulsion) to get into the nucleus. Neutrons are also massive and can carry more energy than a lighter particle.

5. ${}^{17}_{9}\mathrm{F}$ is the residual nucleus. The reaction equation is: ${}^{20}_{10}\mathrm{Ne} + \mathrm{p} \rightarrow \alpha + {}^{17}_{9}\mathrm{F}$.

6. Fission fragments have more neutrons than are required for nuclear stability and will decay by β^- emission in order to convert a neutron to a proton.

7. The energy from nuclear fission appears in the thermal (kinetic) energy of the fission fragments and the neutrons that are emitted, and in the thermal energy of nearby atoms with which they collide.

8. ${}^{239}_{94}\mathrm{Pu}$ has a smaller critical mass than ${}^{235}_{92}\mathrm{U}$. Since there are more neutrons released per decay in Pu-239, fewer nuclei are needed to release sufficient neutrons to create and sustain a chain reaction.

9. Yes, a chain reaction would be possible, since the multiplication factor *f* is greater than 1. However, the chain reaction would progress slowly, and care would have to be taken to prevent neutron loss.

10. When uranium is enriched, the percentage of U-235 nuclei in a given mass of uranium is increased. This process involves the nuclei of the atoms. Chemical processes typically involve the electrons in atoms, and not the nuclei. The chemical behavior of all the isotopes of uranium is nearly identical, therefore chemical means could not be used to separate isotopes and enrich uranium.

11. Neutrons are neutral; they are not repelled by the electrons surrounding the atom or by the positively charged protons in the nucleus. They are able to penetrate easily into the nucleus, and, once there, are held in place by the strong nuclear force. A neutron brings to the nucleus its kinetic energy and the binding energy given up as the neutron is bound to the rest of the nucleus. This binding energy can be very large, and is enough to move the nucleus into an excited state, from which it will fission.

12. The hydrogen atoms in water act as a moderator to slow down the neutrons released during fission reactions. The slower neutrons are more likely to be absorbed by other uranium nuclei to produce further fission reactions, creating a chain reaction that could lead to an explosion. A porous block of uranium in air would be less likely to undergo a chain reaction due to the absence of an effective moderator.

13. Ordinary water does not moderate, or slow down, neutrons as well as heavy water; more neutrons will also be lost to absorption in ordinary water. However, if the uranium in a reactor is highly enriched, there will be many fissionable nuclei available in the fuel rods. It will be likely that the few

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

moderated neutrons will be absorbed by a fissionable nucleus, and it will be possible for a chain reaction to occur.

14. A useful fission reaction is one that is self-sustaining. The neutrons released from an initial fission process can go on to initiate further fission reactions, creating a self-sustaining reaction. If no neutrons were released, then the process would end after a single reaction and not be very useful.

15. Heavy nuclei decay because they are neutron-rich, especially after neutron capture. After fission, the smaller daughter nuclei will still be neutron-rich and relatively unstable, and will emit neutrons in order to move to a more stable configuration. Lighter nuclei are generally more stable with approximately equal numbers of protons and neutrons; heavier nuclei need additional neutrons in order to overcome Coulomb repulsion between the protons.

16. The water in the primary system flows through the core of the reactor and therefore could contain radioactive materials, including deuterium, tritium, and radioactive oxygen isotopes. The use of a secondary system provides for isolation of these potentially hazardous materials from the external environment.

17. Fission is the process in which a larger nucleus splits into two or more fragments, roughly equal in size. Fusion is the process in which smaller nuclei combine to form larger nuclei.

18. Fossil fuel power plants are less expensive to construct and the technology is well known. However, the mining of coal is dangerous and can be environmentally destructive, the transportation of oil can be damaging to the environment through spills, the production of power from both coal and oil contributes to air pollution and the release of greenhouse gases into the environment, and there is a limited supply of both coal and oil. Fission power plants produce no greenhouse gases and virtually no air pollution, and the technology is well known. However, they are expensive to build, produce thermal pollution and radioactive waste, and when accidents occur they tend to be very destructive. Uranium is also dangerous to mine. Fusion power plants produce very little radioactive waste and virtually no air pollution or greenhouse gases. Unfortunately, the technology for large-scale sustainable power production is not yet known, and the pilot plants are very expensive to build.

19. To ignite a fusion reaction, the two nuclei must have enough kinetic energy to overcome electrostatic repulsion and approach each other very closely in a collision. Electrostatic repulsion is proportional to charge and inversely proportional to the square of the distance between the centers of the charge distributions. Both deuterium and tritium have one positive charge, so the charge effect is the same for d-d and d-t ignition. Tritium has one more neutron than deuterium and thus has a larger nucleus. In the d-t ignition, the distance between the centers of the nuclei will be greater than in d-d ignition, reducing the electrostatic repulsion and requiring a lower temperature for fusion ignition.

20. The interiors of stars contain ionized atoms (a plasma) at very high temperature and with a high density of nuclei. The nuclei have high enough kinetic energy and a great enough likelihood of colliding with other nuclei to allow fusion to occur.

21. Stars maintain fusion confinement with gravity. The large amount of mass in a star creates a tremendous gravitational attraction on the gas particles which is able to overcome the repulsive Coulomb force and radiation pressure.

22. Younger women may suffer damage to reproductive cells as well as somatic damage. Genetic damage caused by radiation can cause mutations and be passed on to future generations. A fetus is particularly susceptible to radiation damage due to its small mass and rapid cell development. Since it is quite possible, especially early in a pregnancy, for a woman to be pregnant and not know it, it is

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

reasonable to have lower recommended dose levels for women of childbearing years. Beyond the reproductive years, the acceptable exposure dosage for women can be increased.

23. Alpha particles are relatively large and are generally emitted with relatively low kinetic energies. They are not able to penetrate the skin, and so are not very destructive or dangerous as long as they stay outside the body. If alpha emitters are ingested or breathed, however, the protective layer of skin is bypassed, and the alpha particles, which are charged, can do tremendous amounts of damage to lung or other delicate internal tissue due to ionizing effects. Thus, there are strong rules against eating and drinking around alpha-emitters, and the machining of such materials, which would produce fine dust particles that could be inhaled, can be done only in sealed conditions.

24. The absorbed dose measures the amount of energy deposited per unit mass of absorbing material and is measured in Grays (SI) (1 Gy = 1J/kg) or rads. The effective dose takes into account the type of radiation depositing the energy and is used to determine the biological damage done by the radiation. The effective dose is the absorbed dose multiplied by a quality factor, QF. The effective dose is measured in rem or siverts (SI). 1 Sv of any type of radiation does approximately the same amount of biological damage.

25. Appropriate levels of radiation can kill possibly harmful bacteria and viruses on medical supplies or in food.

26. Allow a radioactive tracer to be introduced into the liquid that flows through the pipe. Then check the pipe with a Geiger counter. When you find the tracer on the outside of the pipe (radiation levels will be higher at that point), you will have found the leak.

Solutions to Problems

1. By absorbing a neutron, the mass number increases by one and the atomic number is unchanged. The product nucleus is $\boxed{{}^{28}_{13}\text{Al}}$. Since the nucleus now has an "extra" neutron, it will decay by $\boxed{\beta^-}$, according to this reaction: ${}^{28}_{13}\text{Al} \rightarrow {}^{28}_{14}\text{Si} + \beta^- + \overline{\nu}_e$. Thus the product is $\boxed{{}^{28}_{14}\text{Si}}$.

2. If the *Q*-value is positive, then no threshold energy is needed.

$$Q = 2m_{{}^{2}_{1}\text{H}}c^2 - m_{{}^{3}_{2}\text{He}}c^2 - m_n c^2 = \left[2\left(2.014082\,\text{u}\right) - 3.016029\,\text{u} - 1.008665\,\text{u}\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2$$

$$= 3.232\,\text{MeV}$$

Thus $\boxed{\text{no threshold energy is required}}$.

3. A "slow" neutron means that it has negligible kinetic energy. If the *Q*-value is positive, then the reaction is possible.

$$Q = m_{{}^{238}_{92}\text{U}}c^2 + m_n c^2 - m_{{}^{239}_{92}\text{U}}c^2 = \left[238.050788\,\text{u} + 1.008665\,\text{u} - 239.054293\,\text{u}\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2$$

$$= 4.807\,\text{MeV}$$

Thus $\boxed{\text{the reaction is possible}}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

4. The *Q*-value tells whether the reaction requires or releases energy.

$$Q = m_{\text{p}}c^2 + m_{{}^{7}_{3}\text{Li}}c^2 - m_{{}^{4}_{2}\text{He}}c^2 - m_{\alpha}c^2 = \left[1.007825\,\text{u} + 7.016005\,\text{u} - 2\left(4.002603\right)\text{u}\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2$$

$$= 17.35\,\text{MeV}$$

The reaction releases 17.35 MeV.

5. The *Q*-value tells whether the reaction requires or releases energy.

$$Q = m_{\alpha}c^2 + m_{{}^{9}_{4}\text{Be}}c^2 - m_{{}^{12}_{6}\text{C}}c^2 - m_{\text{n}}c^2$$

$$= \left[4.002603\,\text{u} + 9.012182\,\text{u} - 12.000000\,\text{u} - 1.008665\,\text{u}\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2 = 5.701\,\text{MeV}$$

The reaction releases 5.701 MeV.

6. (*a*) If the *Q*-value is positive, then no threshold energy is needed.

$$Q = m_{\text{n}}c^2 + m_{{}^{24}_{12}\text{Mg}}c^2 - m_{{}^{23}_{11}\text{Na}}c^2 - m_{\text{d}}c^2$$

$$= \left[1.008665\,\text{u} + 23.985042\,\text{u} - 22.989769\,\text{u} - 2.014082\,\text{u}\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2 = -9.449\,\text{MeV}$$

Thus more energy is required if this reaction is to occur. The 16.00 MeV of kinetic energy is more than sufficient, and so the reaction can occur.

(*b*) 16.00 MeV – 9.449 MeV= 6.55 MeV of energy is released

7. (*a*) If the *Q*-value is positive, then no threshold energy is needed.

$$Q = m_{\text{p}}c^2 + m_{{}^{7}_{3}\text{Li}}c^2 - m_{{}^{4}_{2}\text{He}}c^2 - m_{\alpha}c^2$$

$$= \left[1.007825\,\text{u} + 7.016005\,\text{u} - 2\left(4.002603\,\text{u}\right)\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2 = 17.348\,\text{MeV}$$

Since the *Q*-value is positive, the reaction can occur.

(*b*) The total kinetic energy of the products will be the *Q*-value plus the incoming kinetic energy.

$$K_{\text{total}} = K_{\text{reactants}} + Q = 3.5\,\text{MeV} + 17.348\,\text{MeV} = 20.8\,\text{MeV}$$

8. (*a*) If the *Q*-value is positive, then no threshold energy is needed.

$$Q = m_{\alpha}c^2 + m_{{}^{14}_{7}\text{N}}c^2 - m_{{}^{17}_{8}\text{O}}c^2 - m_{\text{p}}c^2$$

$$= \left[4.002603\,\text{u} + 14.003074\,\text{u} - 16.999132\,\text{u} - 1.007825\,\text{u}\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2 = -1.192\,\text{MeV}$$

Thus more energy is required if this reaction is to occur. The 9.68 MeV of kinetic energy is more than sufficient, and so the reaction can occur.

(*b*) The total kinetic energy of the products will be the *Q*-value plus the incoming kinetic energy.

$$K_{\text{total}} = K_{\text{reactants}} + Q = 9.68\,\text{MeV} - 1.192\,\text{MeV} = 8.49\,\text{MeV}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

9. $Q = m_\alpha c^2 + m_{{}^{16}_{8}\mathrm{O}} c^2 - m_{{}^{20}_{10}\mathrm{Ne}}$

$$= \left[4.002603\,\mathrm{u} + 15.994915\,\mathrm{u} - 19.992440\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{4.730\,\mathrm{MeV}}$$

10. The *Q*-value tells whether the reaction requires or releases energy.

$$Q = m_\mathrm{d} c^2 + m_{{}^{13}_{6}\mathrm{C}} c^2 - m_{{}^{14}_{7}\mathrm{N}} c^2 - m_\mathrm{n} c^2$$

$$= \left[2.014082\,\mathrm{u} + 13.003355\,\mathrm{u} - 14.003074\,\mathrm{u} - 1.008665\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = 5.308\,\mathrm{MeV}$$

The total kinetic energy of the products will be the *Q*-value plus the incoming kinetic energy.

$$K_\mathrm{total} = K_\mathrm{reactants} + Q = 44.4\,\mathrm{MeV} + 5.308\,\mathrm{MeV} = \boxed{49.7\,\mathrm{MeV}}$$

11. The nitrogen-14 absorbs a neutron. Carbon-12 is a product. Thus the reaction is $\mathrm{n} + {}^{14}_{7}\mathrm{N} \rightarrow {}^{14}_{6}\mathrm{C} + ?$. The reactants have 7 protons and 15 nucleons, which means 8 neutrons. Thus the products have 7 protons and 15 nucleons. The unknown product must be a proton. Thus the reaction is $\boxed{\mathrm{n} + {}^{14}_{7}\mathrm{N} \rightarrow {}^{14}_{6}\mathrm{C} + \mathrm{p}}$.

$$Q = m_\mathrm{n} c^2 + m_{{}^{14}_{7}\mathrm{N}} c^2 - m_{{}^{14}_{6}\mathrm{C}} c^2 - m_\mathrm{p} c^2$$

$$= \left[1.008665\,\mathrm{u} + 14.003074\,\mathrm{u} - 14.003242\,\mathrm{u} - 1.007825\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{0.626\,\mathrm{MeV}}$$

12. (*a*) The deuteron is ${}^{2}_{1}\mathrm{H}$, and so the reactants have 4 protons and 8 nucleons. Therefore the reactants have 4 neutrons. Thus the products must have 4 protons and 4 neutrons. That means that X must have 3 protons and 4 neutrons, and so X is $\boxed{{}^{7}_{3}\mathrm{Li}}$.

(*b*) This is called a "stripping" reaction because the lithium nucleus has "stripped" a neutron from the deuteron.

(*c*) The *Q*-value tells whether the reaction requires or releases energy.

$$Q = m_\mathrm{d} c^2 + m_{{}^{6}_{3}\mathrm{Li}} c^2 - m_{{}^{7}_{3}\mathrm{Li}} c^2 - m_\mathrm{p} c^2$$

$$= \left[2.014082\,\mathrm{u} + 6.015123\,\mathrm{u} - 7.016005\,\mathrm{u} - 1.007825\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{5.007\,\mathrm{MeV}}$$

Since the *Q*-value is positive, the reaction is $\boxed{\text{exothermic}}$.

13. (*a*) This is called a "pickup" reaction because the helium has "picked up" a neutron from the carbon nucleus.

(*b*) The alpha is ${}^{4}_{2}\mathrm{He}$. The reactants have 8 protons and 15 nucleons, and so have 7 neutrons. Thus the products must also have 8 protons and 7 neutrons. The alpha has 2 protons and 2 neutrons, and so X must have 6 protons and 5 neutrons. Thus X is $\boxed{{}^{11}_{6}\mathrm{C}}$.

(*c*) The *Q*-value tells whether the reaction requires or releases energy.

$$Q = m_{{}^{3}_{2}\mathrm{He}}c^2 + m_{{}^{12}_{6}\mathrm{C}}c^2 - m_{{}^{11}_{6}\mathrm{C}}c^2 - m_\alpha c^2$$

$$= \left[3.016029\,\mathrm{u} + 12.000000\,\mathrm{u} - 11.011434\,\mathrm{u} - 4.002603\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{1.856\,\mathrm{MeV}}$$

Since the *Q*-value is positive, the reaction is $\boxed{\text{exothermic}}$.

14. (*a*) The product has 16 protons and 16 neutrons. Thus the reactants must have 16 protons and 16 neutrons. Thus the missing nucleus has 15 protons and 16 neutrons, and so is $\boxed{{}^{31}_{15}\mathrm{P}}$.

(*b*) The *Q*-value tells whether the reaction requires or releases energy.

$$Q = m_\mathrm{p}c^2 + m_{{}^{31}_{15}\mathrm{P}}c^2 - m_{{}^{32}_{16}\mathrm{S}}c^2$$

$$= \left[1.007825\,\mathrm{u} + 30.973762\,\mathrm{u} - 31.972071\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{8.864\,\mathrm{MeV}}$$

15. We assume that all of the particles are essentially at rest, and so ignore conservation of momentum. To just make the fluorine nucleus, the *Q*-value plus the incoming kinetic energy should add to 0.

$$K + Q = K + m_\mathrm{p}c^2 + m_{{}^{18}_{8}\mathrm{O}}c^2 - m_{{}^{18}_{9}\mathrm{F}}c^2 - m_\mathrm{n}c^2 = 0 \quad \rightarrow$$

$$m_{{}^{18}_{9}\mathrm{F}}c^2 = K + m_\mathrm{p}c^2 + m_{{}^{18}_{8}\mathrm{O}}c^2 - m_\mathrm{n}c^2 =$$

$$= 2.438\,\mathrm{MeV} + \left[1.007825\,\mathrm{u} + 17.999161\,\mathrm{u} - 1.008665\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2$$

$$= 1.6767874\times10^4\,\mathrm{MeV}$$

$$m_{{}^{18}_{9}\mathrm{F}} = \left(1.6767874\times10^4\,\mathrm{MeV}\right)c^2\left(\frac{1\,\mathrm{u}}{931.5\,\mathrm{MeV}/c^2}\right) = \boxed{18.000938\,\mathrm{u}}$$

16. We assume that the energies are small enough that classical mechanics is applicable, particularly $p = \sqrt{2mK}$ and $K = \frac{1}{2}mv^2$. The least proton kinetic energy is required when the product particles move together and so have the same speed. We write equations for 1-D momentum conservation and for energy conservation, and then combine those to find the required proton energy.

$$p_\mathrm{p} = p_\mathrm{n} + p_\mathrm{N} = \left(m_\mathrm{n} + m_\mathrm{N}\right)v$$

$$K_\mathrm{p} = \frac{p_\mathrm{p}^2}{2m_\mathrm{p}} = \frac{\left[\left(m_\mathrm{n} + m_\mathrm{N}\right)v\right]^2}{2m_\mathrm{p}} = \frac{\left(m_\mathrm{n} + m_\mathrm{N}\right)}{m_\mathrm{p}}\tfrac{1}{2}\left(m_\mathrm{n} + m_\mathrm{N}\right)v^2 = \frac{\left(m_\mathrm{n} + m_\mathrm{N}\right)}{m_\mathrm{p}}\left(K_\mathrm{n} + K_\mathrm{N}\right) \quad \rightarrow$$

$$K_\mathrm{n} + K_\mathrm{N} = \frac{m_\mathrm{p}}{\left(m_\mathrm{n} + m_\mathrm{N}\right)}K_\mathrm{p}$$

$$\text{Energy conservation}: K_\mathrm{p} + Q = K_\mathrm{n} + K_\mathrm{N} = \frac{m_\mathrm{p}}{\left(m_\mathrm{n} + m_\mathrm{N}\right)}K_\mathrm{p} \quad \rightarrow \quad K_\mathrm{p} = -Q\frac{m_\mathrm{n} + m_\mathrm{N}}{m_\mathrm{n} + m_\mathrm{N} - m_\mathrm{p}}$$

Note that this result is also derived in Problem 87. We now substitute in the values for this specific problem.

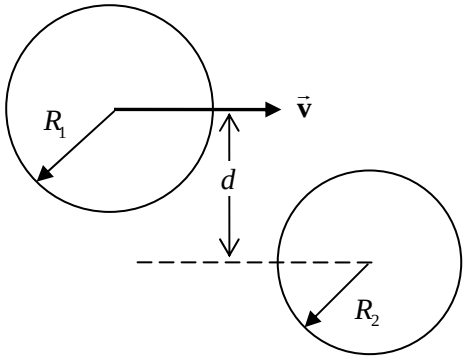
$$K_\mathrm{p} = -Q\frac{m_\mathrm{n} + m_\mathrm{N}}{m_\mathrm{n} + m_\mathrm{N} - m_\mathrm{p}} = -\left[m_{{}^{13}_{6}\mathrm{C}}c^2 + m_\mathrm{p}c^2 - m_{{}^{13}_{7}\mathrm{N}}c^2 - m_\mathrm{n}c^2\right]Q\frac{m_\mathrm{n} + m_\mathrm{N}}{m_\mathrm{n} + m_\mathrm{N} - m_\mathrm{p}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$= -\left\{\left[13.003355\,\text{u} + 1.007825\,\text{u} - 13.005739\,\text{u} - 1.008665\,\text{u}\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2\right]\right.$$
$$\left.\times\left(\frac{1.008665 + 13.005739}{1.008665 + 13.005739 - 1.007825}\right)\right\}$$
$$= \boxed{3.24\,\text{MeV}}$$

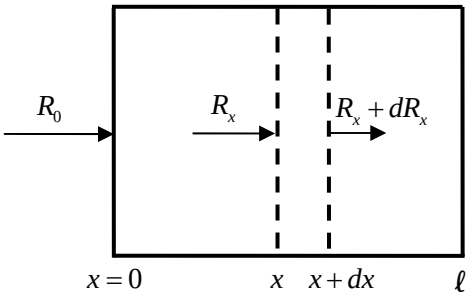
If some intermediate values are used, such as $Q = -3.003\,\text{MeV}$, and $\frac{m_\text{n} + m_\text{N}}{m_\text{n} + m_\text{N} - m_\text{p}} = 1.077$, the mass factor as 1.077, then the value of 3.23 MeV will be obtained.

17. We use the same derivation algebra as in Problem 16, and so jump to the final expression.



$$K_\text{p} = -Q\frac{m_\text{n} + m_\text{N}}{m_\text{n} + m_\text{N} - m_\text{p}} = -\left[m_{^{14}_{6}\text{C}}c^2 + m_\text{p}c^2 - m_{^{14}_{7}\text{N}}c^2 - m_\text{n}c^2\right]Q\frac{m_\text{n} + m_\text{N}}{m_\text{n} + m_\text{N} - m_\text{p}}$$
$$= -\left\{\left[14.003242\,\text{u} + 1.007825\,\text{u} - 14.003074\,\text{u} - 1.008665\,\text{u}\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2\right]\right.$$
$$\left.\times\left(\frac{1.008665 + 14.003074}{1.008665 + 14.003074 - 1.007825}\right)\right\}$$
$$= \boxed{0.671\,\text{MeV}}$$

18. We use Eq, 42-3.



$$\frac{R}{R_0} = n\ell\sigma = \left(1.7\times10^{21}\ \text{nuclei}/\text{m}^3\right)\left(0.120\,\text{m}\right)\left(40\times10^{-28}\,\text{m}^2\right) \approx \boxed{8\times10^{-7}}$$

19. From the figure we see that a collision will occur if $d \le R_1 + R_2$. We calculate the area of the effective circle presented by R_2 to the center of R_1.

$$\sigma = \pi d^2 = \pi\left(R_1 + R_2\right)^2$$

20. At a distance *x* into the target material, particles are arriving at a rate R_x. Due to interactions between the particles and the target material, which remove particles from the stream, particles are arriving at a distance of $x + dx$ at a lower rate of $R_x + dR_x$, where $dR_x < 0$. Thus the collision rate is $-dR_x$. The cross section, given in Eq. 42-3, gives the relationship between the two rates. Also see the diagram.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\sigma = \frac{-dR_x}{R_x n dx} \quad \rightarrow \quad \boxed{-dR_x = R_x n\sigma dx}$$

Integrate the above differential relationship.

$$dR_x = -R_x n\sigma dx \quad \rightarrow \quad \int_{R_0}^{R_x} \frac{1}{R_x} dR_x = -n\sigma \int_0^x dx \quad \rightarrow \quad \ln\left(\frac{R_x}{R_0}\right) = -n\sigma x \quad \rightarrow \quad \boxed{R_x = R_0 e^{-n\sigma x}}$$

$R_0 e^{-n\sigma \ell}$ represents the rate at which particles leave the target material, unaffected by the target material.

21. We use the result from Problem 20, where $R_\ell = R_0 e^{-n\sigma\ell}$. We use the data for the 1.0-cm-thick target to get an expression for $n\sigma$.

$$R_\ell = R_0 e^{-n\sigma\ell} \quad \rightarrow \quad n\sigma = -\frac{1}{\ell}\ln\frac{R_\ell}{R_0} = -\frac{1}{0.010\,\text{m}}\ln 0.25 = 138.63\,\text{m}^{-1}$$

$$R_x = R_0 e^{-n\sigma x} \quad \rightarrow \quad x = -\frac{1}{n\sigma}\ln\frac{R_x}{R_0} = -\left(\frac{1}{138.63\,\text{m}^{-1}}\right)\ln\frac{1}{10^6} = 9.966\times10^{-2}\,\text{m} \approx \boxed{10\,\text{cm}}$$

Note that the answer is correct to 2 significant figures.

22. We assume a 2.0% reaction rate allows us to treat the target as thin. We use Eq. 42-3. We need the volume density of the cadmium atoms.

$$n = \left(8650\,\text{kg/m}^3\right)\left(\frac{6.02\times10^{23}\,\text{atoms}}{0.1139\,\text{kg}}\right) = 4.572\times10^{28}\,\text{nuclei/m}^3$$

(*a*) The cross section for 0.1-eV neutrons is ~ 3000 bn.

$$\frac{R}{R_0} = n\ell\sigma \quad \rightarrow$$

$$\ell = \frac{R}{R_0}\frac{1}{n\sigma} = (0.020)\frac{1}{\left(4.572\times10^{28}\,\text{nuclei/m}^3\right)\left(3000\times10^{-28}\,\text{m}^2\right)} = 1.458\times10^{-6}\,\text{m}$$

$$\approx \boxed{1.5\,\mu\text{m}}$$

(*b*) The cross section for 5.0-eV neutrons is ~ 2 bn.

$$\ell = \frac{R}{R_0}\frac{1}{n\sigma} = (0.020)\frac{1}{\left(4.572\times10^{28}\,\text{nuclei/m}^3\right)\left(2\times10^{-28}\,\text{m}^2\right)} = 2.187\times10^{-3}\,\text{m}$$

$$\approx \boxed{2.2\,\text{mm}}$$

23. The *Q*-value gives the energy released in the reaction, assuming the initial kinetic energy of the neutron is very small.

$$Q = m_n c^2 + m_{^{235}_{92}\text{U}}c^2 - m_{^{141}_{56}\text{Ba}}c^2 - m_{^{92}_{36}\text{Kr}}c^2 - 3m_n c^2$$

$$= \left[1.008665\,\text{u} + 235.043930\,\text{u} - 140.914411\,\text{u} - 91.926156\text{u} - 3(1.008665\,\text{u})\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2$$

$$= \boxed{173.3\,\text{MeV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

24. The *Q*-value gives the energy released in the reaction, assuming the initial kinetic energy of the neutron is very small.

$$Q = m_n c^2 + m_{^{235}_{92}\mathrm{U}} c^2 - m_{^{88}_{38}\mathrm{Sr}} c^2 - m_{^{136}_{54}\mathrm{Xe}} c^2 - 12 m_n c^2$$

$$= \left[1.008665\,\mathrm{u} + 235.043930\,\mathrm{u} - 87.905612\,\mathrm{u} - 135.907219\,\mathrm{u} - 12\left(1.008665\,\mathrm{u}\right)\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2$$

$$= \boxed{126.5\,\mathrm{MeV}}$$

25. The power released is the energy released per reaction times the number of reactions per second.

$$P = \frac{\text{energy}}{\text{reaction}} \times \frac{\#\text{ reactions}}{\text{s}} \rightarrow$$

$$\frac{\#\text{ reactions}}{\text{s}} = \frac{P}{\dfrac{\text{energy}}{\text{reaction}}} = \frac{200\times10^6\,\mathrm{W}}{\left(200\times10^6\,\mathrm{eV}/\mathrm{reaction}\right)\left(1.60\times10^{-19}\,\mathrm{J}/\mathrm{eV}\right)} = \boxed{6\times10^{18}\ \mathrm{reactions}/\mathrm{s}}$$

26. Compare the energy per fission with the rest mass energy.

$$\frac{\text{energy per fission}}{\text{rest mass energy } mc^2} = \frac{200\,\mathrm{MeV}}{\left(235\,\mathrm{u}\right)\left(931.5\,\mathrm{MeV}/c^2\right)c^2} = 9.1\times10^{-4} \approx \boxed{\frac{1}{1100}}$$

27. We convert the 880 watts over a year's time to a mass of uranium.

$$\left(\frac{880}{1}\frac{\mathrm{J}}{\mathrm{s}}\right)\left(\frac{3.156\times10^7\,\mathrm{s}}{1\,\mathrm{y}}\right)\left(\frac{1\,\mathrm{MeV}}{1.60\times10^{-13}\,\mathrm{J}}\right)\left(\frac{1\,\mathrm{fission}}{200\,\mathrm{MeV}}\right)\left(\frac{0.235\,\mathrm{kg}\ ^{235}_{92}\mathrm{U}}{6.02\times10^{23}\,\mathrm{atoms}}\right) = 3.388\times10^{-4}\,\mathrm{kg}\ ^{235}_{92}\mathrm{U}$$

$$\approx \boxed{0.34\,\mathrm{g}\ ^{235}_{92}\mathrm{U}}$$

28. (*a*) The total number of nucleons for the reactants is 236, and so the total number of nucleons for the products must also be 236. The two daughter nuclei have a total of 231 nucleons, so $\boxed{5\text{ neutrons}}$ must be produced in the reaction: $^{235}_{92}\mathrm{U} + \mathrm{n} \rightarrow {}^{133}_{51}\mathrm{Sb} + {}^{98}_{41}\mathrm{Nb} + 5\mathrm{n}$.

(*b*) $$Q = m_{^{235}_{92}\mathrm{U}} c^2 + m_n c^2 - m_{^{133}_{51}\mathrm{Sb}} c^2 - m_{^{98}_{41}\mathrm{Nb}} c^2 - 5 m_n c^2$$

$$= \left[235.043930\,\mathrm{u} + 1.008665\,\mathrm{u} - 132.915250\,\mathrm{u} - 97.910328\,\mathrm{u} - 5\left(1.008665\,\mathrm{u}\right)\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2$$

$$= \boxed{171.1\,\mathrm{MeV}}$$

29. We assume as stated in problems 26 and 27 that an average of 200 MeV is released per fission of a uranium nucleus. Also, note that the problem asks for the mass of $^{238}_{92}\mathrm{U}$, but it is the $^{235}_{92}\mathrm{U}$ nucleus that undergoes the fission. Since $^{238}_{92}\mathrm{U}$ is almost 100% of the natural abundance, we can use the abundance of $^{235}_{92}\mathrm{U}$ from Appendix F as a ratio of $^{235}_{92}\mathrm{U}$ to $^{238}_{92}\mathrm{U}$.

$$\left(3\times10^7\,\mathrm{J}\right)\left(\frac{1\,\mathrm{MeV}}{1.60\times10^{-13}\,\mathrm{J}}\right)\left(\frac{1\,\mathrm{nucleus}\ ^{235}_{92}\mathrm{U}}{200\,\mathrm{MeV}}\right)\left(\frac{1\ \mathrm{atom}\ ^{238}_{92}\mathrm{U}}{0.0072\,\mathrm{atoms}\ ^{235}_{92}\mathrm{U}}\right)\left(\frac{0.238\,\mathrm{kg}}{6.02\times10^{23}\,\mathrm{nuclei}\ ^{238}_{92}\mathrm{U}}\right)$$

$$= 5.15\times10^{-5}\,\mathrm{kg}\ ^{238}_{92}\mathrm{U} \approx \boxed{5\times10^{-5}\,\mathrm{kg}\ ^{238}_{92}\mathrm{U}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

30. Since the reaction is 38% efficient, the fission needs to generate $(950/0.38)\,\text{MW}$ of power. Convert the power rating to a mass of uranium using the factor-label method. We assume 200 MeV is released per fission, as in other problems.

$$\frac{950\times10^6\ \text{J}}{0.38\ \text{s}}\times\frac{1\ \text{atom}}{200\times10^6\,\text{eV}}\times\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\times\frac{0.235\,\text{kg U}}{6.02\times10^{23}\,\text{atoms}}\times\frac{3.156\times10^7\ \text{s}}{1\,\text{y}}=962\,\text{kg}\ {}^{235}_{92}\text{U}$$

$$\approx\boxed{960\,\text{kg}\ {}^{235}_{92}\text{U}}$$

31. We find the number of collisions from the relationship $E_n = E_0\left(\frac{1}{2}\right)^n$, where n is the number of collisions.

$$E_n = E_0\left(\tfrac{1}{2}\right)^n \quad\rightarrow\quad n=\frac{\ln\dfrac{E_n}{E_0}}{\ln\frac{1}{2}}=\frac{\ln\dfrac{0.040\,\text{eV}}{1.0\times10^6\,\text{eV}}}{\ln\frac{1}{2}}=24.58\approx\boxed{25\,\text{collisions}}$$

32. If the uranium splits into equal fragments, each will have an atomic mass number of half of 236, or 118. Each will have a nuclear charge of half of 92, or 46. Calculate the electrical potential energy using Eq. 23-10. The distance between the nuclei will be twice the radius of a nucleus, and the radius is given in Eq. 41-1.

$$U=\frac{1}{4\pi\varepsilon_0}\frac{Q_1Q_2}{r}=\left(8.99\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{(46)^2\left(1.60\times10^{-19}\,\text{C}\right)^2}{2\left(1.2\times10^{-15}\,\text{m}\right)(118)^{1/3}}\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right)=\boxed{260\,\text{MeV}}$$

This is about $\boxed{30\%\text{ larger}}$ than the nuclear fission energy released.

33. The height of the Coulomb barrier is given by the electrostatic potential energy, Eq. 23-10. The distance to use is the sum of the radii of the two particles involved. For the alpha decay, the daughter nucleus is ${}^{232}_{90}\text{Th}$. We assume the fission results in two equal fragments, each with Z = 46 and A = 128. These are palladium nuclei.

$$U_\alpha=\frac{1}{4\pi\varepsilon_0}\frac{Q_\alpha Q_{\text{Th}}}{r_\alpha+r_{\text{Th}}}\ ;\ U_{\text{fission}}=\frac{1}{4\pi\varepsilon_0}\frac{Q_{\text{Pd}}Q_{\text{Pd}}}{r_{\text{Pd}}+r_{\text{Pd}}}$$

$$\frac{U_\alpha}{U_{\text{fission}}}=\frac{\dfrac{1}{4\pi\varepsilon_0}\dfrac{Q_\alpha Q_{\text{Th}}}{r_\alpha+r_{\text{Th}}}}{\dfrac{1}{4\pi\varepsilon_0}\dfrac{Q_{\text{Pd}}Q_{\text{Pd}}}{r_{\text{Pd}}+r_{\text{Pd}}}}=\frac{\dfrac{(2)(90)}{\left(1.2\times10^{-15}\,\text{m}\right)\left(4^{1/3}+232^{1/3}\right)}}{\dfrac{(46)^2}{\left(1.2\times10^{-15}\,\text{m}\right)2\left(128^{1/3}\right)}}=\frac{(2)(90)2\left(128^{1/3}\right)}{(46)^2\left(4^{1/3}+232^{1/3}\right)}=\boxed{0.11}$$

34. The reaction rate is proportional to the number of neutrons causing the reactions. For each fission the number of neutrons will increase by a factor of 1.0004, so in 1000 milliseconds the number of neutrons will increase by a factor of $(1.0004)^{1000}=\boxed{1.5}$.

35. $K=\frac{3}{2}kT=\frac{3}{2}\left(1.38\times10^{-23}\,\text{J/K}\right)\left(2\times10^7\,\text{K}\right)=\boxed{4\times10^{-16}\,\text{J}}$

$$=\tfrac{3}{2}\left(1.38\times10^{-23}\,\text{J/K}\right)\left(2\times10^7\,\text{K}\right)\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right)=2588\,\text{eV}\approx\boxed{3000\,\text{eV}}$$

36. The *Q*-value gives the energy released in the reaction.

$$Q = m_{{}^2_1\mathrm{H}}c^2 + m_{{}^3_1\mathrm{H}}c^2 - m_{{}^4_2\mathrm{He}}c^2 - m_{\mathrm{n}}c^2$$

$$= \left[2.014082\,\mathrm{u} + 3.016049\,\mathrm{u} - 4.002603\,\mathrm{u} - 1.008665\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{17.57\,\mathrm{MeV}}$$

37. Calculate the *Q*-value for the reaction ${}^2_1\mathrm{H} + {}^2_1\mathrm{H} \rightarrow {}^3_2\mathrm{He} + \mathrm{n}$

$$Q = 2m_{{}^2_1\mathrm{H}}c^2 - m_{{}^3_2\mathrm{He}}c^2 - m_{\mathrm{n}}c^2$$

$$= \left[2\left(2.014082\,\mathrm{u}\right) - 3.016029\,\mathrm{u} - 1.008665\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{3.23\,\mathrm{MeV}}$$

38. For the reaction in Eq. 42-7a, if atomic masses are to be used, then one more electron needs to be added to the products side of the equation. Notice that charge is not balanced in the equation as written. The balanced reaction is ${}^1_1\mathrm{H} + {}^1_1\mathrm{H} \rightarrow {}^2_1\mathrm{H} + \mathrm{e}^+ + \nu + \mathrm{e}^-$

$$Q = 2m_{{}^1_1\mathrm{H}}c^2 - m_{{}^2_1\mathrm{H}}c^2 - m_{\mathrm{e}^+}c^2 - m_{\mathrm{e}^-}c^2$$

$$= \left[2\left(1.007825\,\mathrm{u}\right) - 2.014082\,\mathrm{u} - 2\left(0.000549\,\mathrm{u}\right)\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = 0.4378\,\mathrm{MeV} \approx \boxed{0.44\,\mathrm{MeV}}$$

For the reaction in Eq. 42-7b, use atomic masses since there would be two electrons on each side.

$$Q = m_{{}^1_1\mathrm{H}}c^2 + m_{{}^2_1\mathrm{H}}c^2 - m_{{}^3_2\mathrm{He}}c^2$$

$$= \left[1.007825\,\mathrm{u} + 2.014082\,\mathrm{u} - 3.016029\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = 5.4753\,\mathrm{MeV} \approx \boxed{5.48\,\mathrm{MeV}}$$

For the reaction in Eq. 42-7c, use atomic masses since there would be two electrons on each side.

$$Q = 2m_{{}^3_2\mathrm{He}}c^2 - m_{{}^4_2\mathrm{He}}c^2 - 2m_{{}^1_1\mathrm{H}}c^2$$

$$= \left[2\left(3.016029\,\mathrm{u}\right) - 4.002603 - 2\left(1.007825\,\mathrm{u}\right)\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{12.86\,\mathrm{MeV}}$$

39. (*a*) Reaction 42-9a: $\dfrac{4.00\,\mathrm{MeV}}{2\left(2.014082\,\mathrm{u}\right)} \times \dfrac{1\,\mathrm{u}}{1.66\times10^{-27}\,\mathrm{kg}} \times \dfrac{1\,\mathrm{kg}}{1000\,\mathrm{g}} = \boxed{5.98\times10^{23}\ \mathrm{MeV/g}}$

Reaction 42-9b: $\dfrac{3.23\,\mathrm{MeV}}{2\left(2.014082\,\mathrm{u}\right)} \times \dfrac{1\,\mathrm{u}}{1.66\times10^{-27}\,\mathrm{kg}} \times \dfrac{1\,\mathrm{kg}}{1000\,\mathrm{g}} = \boxed{4.83\times10^{23}\ \mathrm{MeV/g}}$

Reaction 42-9c: $\dfrac{17.57\,\mathrm{MeV}}{\left(2.014082\,\mathrm{u} + 3.016049\,\mathrm{u}\right)} \times \dfrac{1\,\mathrm{u}}{1.66\times10^{-27}\,\mathrm{kg}} \times \dfrac{1\,\mathrm{kg}}{1000\,\mathrm{g}} = \boxed{2.10\times10^{24}\ \mathrm{MeV/g}}$

(*b*) Uranium fission (200 MeV per nucleus):

$$\frac{200\,\mathrm{MeV}}{\left(235\,\mathrm{u}\right)} \times \frac{1\,\mathrm{u}}{1.66\times10^{-27}\,\mathrm{kg}} \times \frac{1\,\mathrm{kg}}{1000\,\mathrm{g}} = \boxed{5.13\times10^{23}\ \mathrm{MeV/g}}$$

Reaction 42-9a gives about 17% more energy per gram than uranium fission. Reaction 42-9b gives about 6% less energy per gram than uranium fission. Reaction 42-9c gives about 4 times as much energy per gram than uranium fission.

40. Calculate the *Q*-value for the reaction ${}^{238}_{92}\mathrm{U} + \mathrm{n} \rightarrow {}^{239}_{92}\mathrm{U}$

$$Q = m_{{}^{238}_{92}\mathrm{U}}c^2 + m_{\mathrm{n}}c^2 - m_{{}^{239}_{92}\mathrm{U}}c^2$$

$$= \left[238.050788\,\mathrm{u} + 1.008665\,\mathrm{u} - 239.054293\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{4.807\,\mathrm{MeV}}$$

41. The reaction of Eq. 42-9b consumes 2 deuterons and releases 3.23 MeV of energy. The amount of energy needed is the power times the elapsed time, and the energy can be related to the mass of deuterium by the reaction.

$$\left(850\frac{\mathrm{J}}{\mathrm{s}}\right)(1\,\mathrm{yr})\left(3.156\times10^7\,\frac{\mathrm{s}}{\mathrm{yr}}\right)\left(\frac{1\mathrm{MeV}}{1.60\times10^{-13}\,\mathrm{J}}\right)\left(\frac{2\,\mathrm{d}}{3.23\,\mathrm{MeV}}\right)\left(\frac{2.014\times10^{-3}\mathrm{kg}}{6.02\times10^{23}\,\mathrm{d}}\right)$$

$$= 3.473\times10^{-4}\,\mathrm{kg} = \boxed{0.35\,\mathrm{g}}$$

42. (*a*) The reactants have a total of 3 protons and 7 neutrons, and so the products should have the same. After accounting for the helium, there are 3 neutrons and 1 proton in the other product, and so it must be tritium, ${}^{3}_{1}\mathrm{He}$. The reaction is ${}^{6}_{3}\mathrm{Li} + {}^{1}_{0}\mathrm{n} \rightarrow {}^{4}_{2}\mathrm{He} + {}^{3}_{1}\mathrm{H}$.

(*b*) The *Q*-value gives the energy released.

$$Q = m_{{}^{6}_{3}\mathrm{Li}}c^2 + m_{{}^{1}_{0}\mathrm{n}}c^2 - m_{{}^{4}_{2}\mathrm{He}}c^2 - m_{{}^{3}_{1}\mathrm{He}}c^2$$

$$= \left[6.015123\,\mathrm{u} + 1.008665\,\mathrm{u} - 4.002603\,\mathrm{u} - 3.016049\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{4.784\,\mathrm{MeV}}$$

43. Assume that the two reactions take place at equal rates, so they are both equally likely. Then from the reaction of 4 deuterons, there would be a total of 7.228 MeV of energy released, or 1.807 MeV per deuteron on the average. A total power of $\dfrac{1250\,\mathrm{MW}}{0.33} = 3788\,\mathrm{MW}$ must be obtained from the fusion reactions to provide the required 1250 MW output, because of the 330% efficiency. We convert the power to a number of deuterons based on the energy released per reacting deuteron, and then convert that to an amount of water using the natural abundance of deuterium.

$$3788\,\mathrm{MW} \rightarrow \left[\begin{array}{l}\left(3788\times10^6\,\dfrac{\mathrm{J}}{\mathrm{s}}\right)\left(\dfrac{3600\,\mathrm{s}}{1\mathrm{h}}\right)\left(\dfrac{1\mathrm{MeV}}{1.60\times10^{-13}\,\mathrm{J}}\right)\left(\dfrac{1\,\mathrm{d}}{1.807\,\mathrm{MeV}}\right)\left(\dfrac{1\text{ H atom}}{0.000115\text{ d's}}\right)\times \\ \left(\dfrac{1\mathrm{H_2O\,molecule}}{2\text{ H atoms}}\right)\left(\dfrac{0.018\text{ kg }\mathrm{H_2O}}{6.02\times10^{23}\,\mathrm{molecules}}\right)\end{array}\right]$$

$$= 6131\,\mathrm{kg/h} \approx \boxed{6100\,\mathrm{kg/h}}$$

44. We assume that the reactants are at rest when they react, and so the total momentum of the system is 0. As a result, the momenta of the two products are equal in magnitude. The available energy of 17.57 MeV is much smaller than the masses involved, and so we use the non-relativistic relationship between momentum and kinetic energy, $K = \dfrac{p^2}{2m} \rightarrow p = \sqrt{2mK}$.

$$K_{{}^{4}_{2}\mathrm{He}} + K_{\mathrm{n}} = K_{\mathrm{total}} = 17.57\,\mathrm{MeV} \qquad p_{{}^{4}_{2}\mathrm{He}} = p_{\mathrm{n}} \rightarrow \sqrt{2m_{{}^{4}_{2}\mathrm{He}}K_{{}^{4}_{2}\mathrm{He}}} = \sqrt{2m_{\mathrm{n}}K_{\mathrm{n}}} \rightarrow$$

$$m_{{}^{4}_{2}\mathrm{He}}K_{{}^{4}_{2}\mathrm{He}} = m_{\mathrm{n}}K_{\mathrm{n}} \rightarrow m_{{}^{4}_{2}\mathrm{He}}K_{{}^{4}_{2}\mathrm{He}} = m_{\mathrm{n}}\left(K_{\mathrm{total}} - K_{{}^{4}_{2}\mathrm{He}}\right) \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$K_{^4_2\text{He}} = \frac{m_\text{n}}{m_{^4_2\text{He}} + m_\text{n}} K_\text{total} = \left(\frac{1.008665}{4.002603 + 1.008665}\right) 17.57\,\text{MeV} = 3.536\,\text{MeV} \approx \boxed{3.5\,\text{MeV}}$$

$$K_\text{n} = K_\text{total} - K_{^4_2\text{He}} = 17.57\,\text{MeV} - 3.54\,\text{MeV} = 14.03\,\text{MeV} \approx \boxed{14\,\text{MeV}}$$

If the plasma temperature were significantly higher, then the approximation of 0 kinetic energy being brought into the reaction would not be reasonable. Thus the results would depend on plasma temperature. A higher plasma temperature would result in higher values for the energies.

45. In Eq. 42-9a, 4.00 MeV of energy is released for every 2 deuterium atoms. The mass of water can be converted to a number of deuterium atoms.

$$\left(1.00\,\text{kg}\,\text{H}_2\text{O}\right)\left(\frac{6.02\times10^{23}\,\text{H}_2\text{O}}{0.018\,\text{kg}\,\text{H}_2\text{O}}\right)\left(\frac{2\,\text{H}}{1\,\text{H}_2\text{O}}\right)\left(\frac{1.15\times10^{-4}\,\text{d}}{1\,\text{H}}\right) = 7.692\times10^{21}\,\text{d nuclei} \;\rightarrow$$

$$\left(7.692\times10^{21}\,\text{d nuclei}\right)\left(\frac{4.00\times10^{6}\,\text{eV}}{2\,\text{d atoms}}\right)\left(\frac{1.60\times10^{-19}\,\text{J}}{1\,\text{eV}}\right) = \boxed{2.46\times10^{9}\,\text{J}}$$

As compared to gasoline: $\dfrac{2.46\times10^{9}\,\text{J}}{5\times10^{7}\,\text{J}} \approx$ $\boxed{\text{50 times more than gasoline}}$

46. (*a*) We follow the method of Example 42-10. The reaction is ${}^{12}_{6}\text{C} + {}^{1}_{1}\text{H} \rightarrow {}^{13}_{7}\text{N} + \gamma$. We calculate the potential energy of the particles when they are separated by the sum of their radii. The radii are calculated from Eq. 41-1.

$$K_\text{total} = \frac{1}{4\pi\varepsilon_0}\frac{q_\text{C}q_\text{H}}{r_\text{C} + r_\text{H}} = \left(8.99\times10^{9}\ \text{N}\bullet\text{m}^2/\text{C}^2\right)\frac{(6)(1)\left(1.60\times10^{-19}\,\text{C}\right)^2}{\left(1.2\times10^{-15}\,\text{m}\right)\left(1^{1/3} + 12^{1/3}\right)}\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right)$$

$$= 2.19\,\text{MeV}$$

For the d-t reaction, Example 42-10 shows $K_\text{total} = 0.45\,\text{MeV}$. Find the ratio of the two energies.

$$\frac{K_\text{C}}{K_\text{d-t}} = \frac{2.19\,\text{MeV}}{0.45\,\text{MeV}} = 4.9$$

$\boxed{\text{The carbon reaction requires about 5 times more energy than the d-t reaction.}}$

(*b*) Since the kinetic energy is proportional to the temperature by $\overline{K} = \frac{3}{2}kT$, since the kinetic energy has to increase by a factor of 5, so does the temperature.

$T = 4.9\left(3\times10^{8}\,\text{K}\right) \approx \boxed{1.5\times10^{9}\,\text{K}}$.

47. (*a*) No carbon is consumed in this cycle because one ${}^{12}_{6}\text{C}$ nucleus is required in the first step of the cycle, and one ${}^{12}_{6}\text{C}$ nucleus is produced in the last step of the cycle. The net effect of the cycle can be found by adding all the reactants and all the products together, and canceling what appears on both sides of the reaction.

$${}^{12}_{6}\text{C} + {}^{1}_{1}\text{H} \rightarrow {}^{13}_{7}\text{N} + \gamma$$

$${}^{13}_{7}\text{N} \rightarrow {}^{13}_{6}\text{C} + \text{e}^{+} + \nu$$

$${}^{13}_{6}\text{C} + {}^{1}_{1}\text{H} \rightarrow {}^{14}_{7}\text{N} + \gamma$$

$${}^{14}_{7}\text{N} + {}^{1}_{1}\text{H} \rightarrow {}^{15}_{8}\text{O} + \gamma$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$^{15}_{8}\mathrm{O} \rightarrow {}^{15}_{7}\mathrm{N} + \mathrm{e}^{+} + \nu$$
$$^{15}_{7}\mathrm{N} + {}^{1}_{1}\mathrm{H} \rightarrow {}^{12}_{6}\mathrm{C} + {}^{4}_{2}\mathrm{He}$$

$$^{12}_{6}\mathrm{C} + {}^{1}_{1}\mathrm{H} + {}^{13}_{7}\mathrm{N} + {}^{13}_{6}\mathrm{C} + {}^{1}_{1}\mathrm{H} + {}^{14}_{7}\mathrm{N} + {}^{1}_{1}\mathrm{H} + {}^{15}_{8}\mathrm{O} + {}^{15}_{7}\mathrm{N} + {}^{1}_{1}\mathrm{H}$$
$$\rightarrow \quad {}^{13}_{7}\mathrm{N} + \gamma + {}^{13}_{6}\mathrm{C} + \mathrm{e}^{+} + \nu + {}^{14}_{7}\mathrm{N} + \gamma + {}^{15}_{8}\mathrm{O} + \gamma + {}^{15}_{7}\mathrm{N} + \mathrm{e}^{+} + \nu + {}^{12}_{6}\mathrm{C} + {}^{4}_{2}\mathrm{He}$$

$$4\,{}^{1}_{1}\mathrm{H} \rightarrow {}^{4}_{2}\mathrm{He} + 2\,\mathrm{e}^{+} + 2\nu + 3\gamma$$

There is a difference of one gamma ray in the process, as mentioned in the text.

(*b*) To use the values from Appendix F, we must be sure that number of electrons is balanced as well as the number of protons and neutrons. The above "net" equation does not consider the electrons that neutral nuclei would have, because it does not conserve charge. What the above reaction really represents (ignoring the gammas and neutrinos) is the following.

$$4\,{}^{1}_{1}\mathrm{H} \rightarrow {}^{4}_{2}\mathrm{He} + 2\,\mathrm{e}^{+} \quad \Rightarrow \quad 4\,{}^{1}_{1}\mathrm{p} \rightarrow 2\,{}^{1}_{1}\mathrm{p} + 2\,{}^{1}_{0}\mathrm{n} + 2\mathrm{e}^{+}$$

To use the values from Appendix F, we must add 4 electrons to each side of the reaction.

$$\left(4\,{}^{1}_{1}\mathrm{p} + 4\mathrm{e}^{-}\right) \rightarrow \left(2\,{}^{1}_{1}\mathrm{p} + 2\mathrm{e}^{-} + 2\,{}^{1}_{0}\mathrm{n}\right) + 2\mathrm{e}^{+} + 2\mathrm{e}^{-} \quad \Rightarrow \quad 4\,{}^{1}_{1}\mathrm{H} \rightarrow {}^{4}_{2}\mathrm{He} + 2\mathrm{e}^{+} + 2\mathrm{e}^{-}$$

The energy produced in the reaction is the *Q*-value.

$$Q = 4m_{{}^{1}_{1}\mathrm{H}}c^2 - m_{{}^{4}_{2}\mathrm{He}}c^2 - 4m_{\mathrm{e}}$$
$$= \left[4\left(1.007825\,\mathrm{u}\right) - 4.002603\,\mathrm{u} - 4\left(0.000549\,\mathrm{u}\right)\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = 24.69\,\mathrm{MeV}$$

As mentioned at the top of page 1143, the positrons and the electrons annihilate to produce another 2.04 MeV, so the total energy released is $24.69\,\mathrm{MeV} + 2\left(1.02\,\mathrm{MeV}\right) = \boxed{26.73\,\mathrm{MeV}}$.

(*c*) In some reactions extra electrons must be added in order to use the values from Appendix F.

The <u>first equation</u> is electron-balanced, and so Appendix F can be used.

$$Q = m_{{}^{12}_{6}\mathrm{C}}c^2 + m_{{}^{1}_{1}\mathrm{H}}c^2 - m_{{}^{13}_{7}\mathrm{N}}c^2$$
$$= \left[12.000000\,\mathrm{u} + 1.007825\,\mathrm{u} - 13.005739\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{1.943\,\mathrm{MeV}}$$

The <u>second equation</u> needs to have another electron, so that $^{13}_{7}\mathrm{N} \rightarrow {}^{13}_{6}\mathrm{C} + \mathrm{e}^{-} + \mathrm{e}^{+} + \nu$.

$$Q = m_{{}^{13}_{7}\mathrm{N}}c^2 - m_{{}^{13}_{6}\mathrm{C}}c^2 - 2m_{\mathrm{e}}c^2$$
$$= \left[13.005739\,\mathrm{u} - 13.003355\,\mathrm{u} - 2\left(0.000549\,\mathrm{u}\right)\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = 1.198\,\mathrm{MeV}$$

We must include an electron-positron annihilation in this reaction.

$$1.198\,\mathrm{MeV} + 1.02\,\mathrm{MeV} = \boxed{2.218\,\mathrm{MeV}}$$

The <u>third equation</u> is electron-balanced.

$$Q = m_{{}^{13}_{6}\mathrm{C}}c^2 + m_{{}^{1}_{1}\mathrm{H}}c^2 - m_{{}^{14}_{7}\mathrm{N}}c^2$$
$$= \left[13.003355\,\mathrm{u} + 1.007825\,\mathrm{u} - 14.003074\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{7.551\,\mathrm{MeV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The fourth equation is electron-balanced.

$$Q = m_{{}^{14}_{7}\mathrm{N}}c^2 + m_{{}^{1}_{1}\mathrm{H}}c^2 - m_{{}^{15}_{8}\mathrm{O}}c^2$$

$$= \left[14.003074\,\mathrm{u} + 1.007825\,\mathrm{u} - 15.003066\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{7.296\,\mathrm{MeV}}$$

The fifth equation needs to have another electron, so that ${}^{15}_{8}\mathrm{O} \rightarrow {}^{15}_{7}\mathrm{N} + \mathrm{e}^- + \mathrm{e}^+ + \nu$.

$$Q = m_{{}^{15}_{8}\mathrm{O}}c^2 - m_{{}^{15}_{7}\mathrm{N}}c^2 - 2m_{\mathrm{e}}c^2$$

$$= \left[15.003066\,\mathrm{u} - 15.000109\,\mathrm{u} - 2\left(0.000549\,\mathrm{u}\right)\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = 1.732\,\mathrm{MeV}$$

We must include an electron-positron annihilation in this reaction.

$$1.732\,\mathrm{MeV} + 1.02\,\mathrm{MeV} = \boxed{2.752\,\mathrm{MeV}}$$

The sixth equation is electron-balanced.

$$Q = m_{{}^{15}_{7}\mathrm{N}}c^2 + m_{{}^{1}_{1}\mathrm{H}}c^2 - m_{{}^{12}_{6}\mathrm{C}}c^2 - m_{{}^{4}_{2}\mathrm{He}}c^2$$

$$= \left[15.000109\,\mathrm{u} + 1.007825\,\mathrm{u} - 12.000000\,\mathrm{u} - 4.002603\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2$$

$$= \boxed{4.966\,\mathrm{MeV}}$$

The total is found as follows.

$$1.943\,\mathrm{MeV} + 2.218\,\mathrm{MeV} + 7.551\,\mathrm{MeV} + 7.296\,\mathrm{MeV} + 2.752\,\mathrm{MeV} + 4.966\,\mathrm{MeV}$$

$$= 26.73\,\mathrm{MeV}$$

(*d*) It takes a higher temperature for this reaction than for a proton-proton reaction because the reactants have to have more initial kinetic energy to overcome the Coulomb repulsion of one nucleus to another. In particular, the carbon and nitrogen nuclei have higher Z values leading to the requirement of a high temperature in order for the protons to get close enough to fuse with them.

48. Because the quality factor of alpha particles is 20 and the quality factor of X-rays is 1, it takes 20 times as many rads of X-rays to cause the same biological damage as compared to alpha particles. Thus the 250 rads of alpha particles is equivalent to $250\,\mathrm{rad} \times 20 = \boxed{5000\,\mathrm{rad}}$ of X-rays.

49. Use Eq. 42-11b to relate Sv to Gy. From Table 42.1, the quality factor of gamma rays is 1, and so the number of Sv is equal to the number of Gy. Thus $4.0\,\mathrm{Sv} = \boxed{4.0\,\mathrm{Gy}}$.

50. A gray is 1 Joule per kg, according to Eq. 42-10.

$$3.0\frac{\mathrm{J}}{\mathrm{kg}} \times 65\,\mathrm{kg} = 195\,\mathrm{J} \approx \boxed{200\,\mathrm{J}} \text{ (2 sig. fig.)}$$

51. The biological damage is measured by the effective dose, Eq. 42-11b.

$$65\,\mathrm{rad\ fast\ neutrons} \times 10 = x\,\mathrm{rad\ slow\ neutrons} \times 3 \rightarrow$$

$$x = \frac{65\,\mathrm{rad} \times 10}{3} = \boxed{220\,\mathrm{rad\ slow\ neutrons}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

52. (*a*) Since the quality factor for protons is 1, the effective dose (in rem) is the same as the absorbed dose (in rad). Thus the absorbed dose is $\boxed{1.0\text{ rad or }0.010\text{ Gy}}$.

(*b*) A Gy is a J per kg.

$$(0.010\,\text{Gy})\left(\frac{1\,\text{J/kg}}{1\,\text{Gy}}\right)(0.25\,\text{kg})\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right)\left(\frac{1\,\text{p}}{1.2\times10^{6}\,\text{eV}}\right)=\boxed{1.3\times10^{10}\,\text{p}}$$

53. The counting rate will be 85% of 25% of the activity.

$$\left(0.035\times10^{-6}\,\text{Ci}\right)\left(\frac{3.7\times10^{10}\,\text{decays/s}}{1\,\text{Ci}}\right)\left(\frac{1\,\beta}{1\,\text{decay}}\right)(0.25)(0.85)=275.2\,\text{counts/s}\approx\boxed{280\,\text{counts/s}}$$

54. The two definitions of roentgen are 1.6×10^{12} ion pairs/g produced by the radiation, and the newer definition of 0.878×10^{-2} J/kg deposited by the radiation. Start with the current definition, and relate them by the value of 35 eV per ion pair.

$$1\,\text{R}=\left(0.878\times10^{-2}\,\text{J/kg}\right)\left(1\,\text{kg}/1000\,\text{g}\right)\left(1\,\text{eV}/1.60\times10^{-19}\,\text{J}\right)\left(1\,\text{ion pair}/35\,\text{eV}\right)$$

$$=1.567\times10^{12}\,\text{ion pairs/g}$$

The two values of ion pairs per gram are within about 2% of each other.

55. We approximate the decay rate as constant, and find the time to administer 36 Gy. If that calculated time is significantly shorter than the half-life of the isotope, then the approximation is reasonable. If 1.0 mCi delivers about 10 mGy/min, then 1.6 mCi would deliver 16 mGy/min.

$$\text{dose}=\text{rate}\times\text{time}\ \rightarrow\ \text{time}=\frac{\text{dose}}{\text{rate}}=\frac{36\,\text{Gy}}{16\times10^{-3}\,\text{Gy/min}}\left(\frac{1\,\text{day}}{1440\,\text{min}}\right)=1.56\,\text{day}\approx\boxed{1.6\,\text{day}}$$

This is only about 11% of a half life, so our approximation is reasonable.

56. Since the half-life is long (5730 yr) we will consider the activity as constant over a short period of time. Use the definition of the curie from Section 42-6.

$$\left(2.00\times10^{-6}\,\text{Ci}\right)\left(\frac{3.70\times10^{10}\,\text{decays/s}}{1\,\text{Ci}}\right)=7.40\times10^{4}\,\text{decays/s}=\left|\frac{dN}{dt}\right|=\lambda N=\frac{\ln 2}{T_{1/2}}N\ \rightarrow$$

$$N=\left|\frac{dN}{dt}\right|\frac{T_{1/2}}{\ln 2}=\left(7.4\times10^{4}\,\text{decays/s}\right)\left(\frac{5730\,\text{y}}{\ln 2}\right)\left(3.156\times10^{7}\,\text{s/y}\right)=1.931\times10^{16}\,\text{nuclei}$$

$$1.931\times10^{16}\,\text{nuclei}\left(\frac{0.014\,\text{kg}}{6.02\times10^{23}\,\text{nuclei}}\right)=\boxed{4.49\times10^{-10}\,\text{kg}}$$

57. (*a*) According to Appendix F, ${}^{131}_{53}\text{I}$ decays by beta decay.

$$\boxed{{}^{131}_{53}\text{I}\ \rightarrow\ {}^{131}_{54}\text{Xe}+\beta^{-}+\bar{\nu}}$$

(*b*) The number of nuclei present is given by Eq. 41-6.

$$N=N_0e^{-\lambda t}\ \rightarrow\ t=-\frac{\ln\dfrac{N}{N_0}}{\lambda}=-\frac{T_{1/2}\ln\dfrac{N}{N_0}}{\ln 2}=-\frac{(8.0\,\text{d})\ln 0.070}{\ln 2}=30.69\,\text{d}\approx\boxed{31\,\text{d}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) The activity is given by $dN/dt = -\lambda N$. This can be used to find the number of nuclei, and then the mass can be found. Note that the numeric value of dN/dt is negative since the number of undecayed nuclei is decreasing.

$$\frac{dN}{dt} = -\lambda N \quad \rightarrow$$

$$N = -\frac{dN/dt}{\lambda} = \frac{(T_{1/2})(-dN/dt)}{\ln 2} = \frac{(8.0\,\text{d})(86400\,\text{s/d})(1\times10^{-3}\,\text{Ci})(3.70\times10^{10}\,\text{decays/s})}{\ln 2}$$

$$= 3.69\times10^{13}\,\text{nuclei}$$

$$3.69\times10^{13}\,\text{nuclei}\left(\frac{0.131\,\text{kg}}{6.02\times10^{23}\,\text{nuclei}}\right) \approx \boxed{8\times10^{-12}\,\text{kg}} = 8\,\text{ng}$$

58. The activity is converted to decays per day, then to energy per year, and finally to a dose per year. The potassium decays by gammas and betas, according to Appendix F. Gammas and betas have a quality factor of 1, so the number of Sv is the same as the number of Gy, and the number of rem is the same as the number of rad.

$$\left(2000\times10^{-12}\,\frac{\text{Ci}}{\text{L}}\right)\left(3.70\times10^{10}\,\frac{\text{decays/s}}{1\,\text{Ci}}\right)(12\,\text{hr})\left(\frac{3600\,\text{s}}{\text{hr}}\right)\left(0.5\frac{\text{L}}{\text{day}}\right) = 1.598\times10^{6}\,\frac{\text{decays}}{\text{day}}$$

$$\left(1.598\times10^{6}\,\frac{\text{decays}}{\text{day}}\right)\left(365\frac{\text{day}}{\text{yr}}\right)(0.10)\left(1.5\frac{\text{MeV}}{\text{decay}}\right)\left(\frac{1.60\times10^{-13}\,\text{J}}{\text{MeV}}\right) = 1.40\times10^{-5}\,\frac{\text{J}}{\text{yr}}$$

(*a*) For the adult, use a mass of 60 kg.

$$\text{Effective dose} = \left(1.40\times10^{-5}\,\frac{\text{J}}{\text{yr}}\right)\left(\frac{1}{60\,\text{kg}}\right)\left(\frac{1\text{Gy}}{1\text{J/kg}}\right)\left(\frac{1\text{Sv}}{1\text{Gy}}\right)$$

$$= 2.33\times10^{-7}\,\text{Sv/yr}\left(\frac{10^{5}\,\text{mrem}}{\text{Sv}}\right) = 2.33\times10^{-2}\,\text{mrem/yr}$$

$$\approx \boxed{2\times10^{-7}\,\text{Sv/yr}} \text{ or } \boxed{2\times10^{-2}\,\text{mrem/yr}}$$

$$\text{fraction of allowed dose} = \frac{2.33\times10^{-2}\,\frac{\text{mrem}}{\text{year}}}{100\,\frac{\text{mrem}}{\text{year}}} \approx \boxed{2\times10^{-4}\,\text{times the allowed dose}}$$

(*b*) For the baby, the only difference is that the mass is 10 times smaller, so the effective dose is 10 times bigger. The results are as follows.

$$\approx \boxed{2\times10^{-6}\,\text{Sv/yr}},\ \boxed{0.2\,\text{mrem/yr}},\ \text{and}\ \boxed{2\times10^{-3}\,\text{times the allowed dose}}$$

59. Each decay releases one gamma ray of energy 122 keV. Half of that energy is deposited in the body. The activity tells at what rate the gamma rays are released into the body. We assume the activity is constant.

$$(1.55\times10^{-6}\,\text{Ci})\left(3.70\times10^{10}\,\frac{\gamma/\text{s}}{\text{Ci}}\right)(86400\,\text{s/day})(0.50)(122\,\text{keV}/\gamma)(1.60\times10^{-16}\,\text{J/keV})\left(\frac{1}{58\,\text{kg}}\right)$$

$$= 8.338\times10^{-7}\,\frac{\text{J/kg}}{\text{day}} \approx \boxed{8.3\times10^{-7}\,\frac{\text{Gy}}{\text{day}}}$$

60. We use the dose, the mass of the beef, and the energy per electron to find the number of electrons.

$$4.5\times10^{3}\,\text{Gy}\left(\frac{1\,\text{J/kg}}{1\,\text{Gy}}\right)(5\,\text{kg})\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right)\left(\frac{1\,\text{e}^-}{1.2\,\text{MeV}}\right)=\boxed{1\times10^{17}\,\text{e}^-}$$

61. (*a*) The reaction has $Z = 86$ and $A = 222$ for the parent nucleus. The alpha has $Z = 2$ and $A = 4$, so the daughter nucleus must have $Z = 84$ and $A = 218$. That makes the daughter nucleus $\boxed{^{218}_{84}\text{Po}}$.

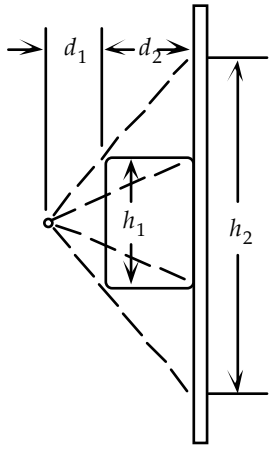
(*b*) From Figure 41-12, polonium-218 is $\boxed{\text{radioactive}}$. It decays via both $\boxed{\text{alpha and beta decay}}$, each with a half-life of $\boxed{3.1\text{ minutes}}$.

(*c*) The daughter nucleus is not a noble gas, so it is $\boxed{\text{chemically reacting}}$. It is in the same group as oxygen, so it might react with many other elements chemically.

(*d*) The activity is given by Eq. 41-7a, $R = \lambda N = \dfrac{\ln 2}{T_{1/2}}N$.

$$R=\frac{\ln 2}{T_{1/2}}N=\frac{\ln 2}{(3.8235\,\text{d})(86400\,\text{s/d})}\left(1.6\times10^{-9}\,\text{g}\right)\frac{6.02\times10^{23}\,\text{nuclei}}{222\,\text{g}}$$

$$=9.104\times10^{6}\,\text{decays/s}\approx\boxed{9.1\times10^{6}\,\text{Bq}}=0.25\,\text{mCi}$$



To find the activity after 1 month, use Eq. 41-7d.

$$R=R_0e^{-\frac{\ln 2}{T_{1/2}}t}=\left(9.104\times10^{6}\,\text{decays/s}\right)e^{-\frac{\ln 2}{(3.8235\,\text{d})}(30\,\text{d})}=3.956\times10^{4}\,\text{decays/s}$$

$$\approx\boxed{4.0\times10^{4}\,\text{Bq}}=1.1\,\mu\text{Ci}$$

62. (*a*) For parallel rays, the object and the image will be the same size, and so the magnification is $\boxed{1}$.

(*b*) When the film is pressed against the back, the image of the back on the film will be the same size as the back, since there is no appreciable spreading of the rays from the back to the film. So $m_{\text{back}} = 1$. But, from the diagram, we see that the rays which define the boundary of the area on the chest will have a much larger image with the film at the back. The height of the image is proportional to the distance from the point source, since the rays travel in straight lines.

$$m_{\text{front}}=\frac{h_2}{h_1}=\frac{d_1+d_2}{d_1}=1+\frac{d_2}{d_1}=1+\frac{25}{15}=2.67$$

So the range of magnifications is $1\le m\le 2.67$, depending on which part of the body is being imaged.

63. The frequency is given in Example 42-14 to be 42.58 MHz. Use that to find the wavelength.

$$c=f\lambda\ \rightarrow\ \lambda=\frac{c}{f}=\frac{2.998\times10^{8}\,\text{m/s}}{42.58\times10^{6}\,\text{Hz}}=\boxed{7.041\,\text{m}}$$

This lies in the $\boxed{\text{radio wave}}$ portion of the spectrum.

64. We use Eq. 42-12, but with the neutron's magnetic moment.

$$hf = 2\mu_n B_T \rightarrow$$

$$B_T = \frac{hf}{2\mu_n} = \frac{hf}{2(0.7023)\mu_N} = \frac{hf}{2(0.7023)\dfrac{eh}{4\pi m_p}} = \frac{2\pi f m_p}{(0.7023)e}$$

$$= \frac{2\pi\left(42.58\times10^6\,\text{Hz}\right)\left(1.673\times10^{-27}\,\text{kg}\right)}{(0.7023)\left(1.602\times10^{-19}\,\text{C}\right)} = \boxed{3.978\,\text{T}}$$

65. (*a*) The reaction is ${}^{9}_{4}\text{Be} + {}^{4}_{2}\text{He} \rightarrow \text{n} + ?$. There are 6 protons and 13 nucleons in the reactants, and so there must be 6 protons and 13 nucleons in the products. The neutron is 1 nucleon, so the other product must have 6 protons ad 12 nucleons. Thus it is $\boxed{{}^{12}_{6}\text{C}}$.

(*b*) $Q = m_{{}^{9}_{4}\text{Be}}c^2 + m_{{}^{4}_{2}\text{He}}c^2 - m_n c^2 - m_{{}^{12}_{6}\text{C}}c^2$

$$= \left[9.012182\,\text{u} + 4.002603\,\text{u} - 1.008665\,\text{u} - 12.000000\,\text{u}\right]\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2 = \boxed{5.701\,\text{MeV}}$$

66. The energy and temperature are related by the Boltzmann constant, which has units of energy/temperature.

$$k = 1.381\times10^{-23}\frac{\text{J}}{\text{K}}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}\times\frac{1\,\text{keV}}{1000\,\text{eV}} = \boxed{8.620\times10^{-8}\,\text{keV/K}}$$

67. From Eq. 18-5, the average speed of a gas molecule (root mean square speed) is inversely proportional to the square root of the mass of the molecule, if the temperature is constant. We assume that the two gases are in the same environment and so at the same temperature. We use UF_6 molecules for the calculations.

$$\frac{v_{{}^{235}_{92}\text{UF}_6}}{v_{{}^{238}_{92}\text{UF}_6}} = \sqrt{\frac{m_{{}^{238}_{92}\text{UF}_6}}{m_{{}^{235}_{92}\text{UF}_6}}} = \sqrt{\frac{238+6(19)}{235+6(19)}} = \boxed{1.0043:1}$$

68. (*a*) We assume that the energy produced by the fission was 200 MeV per fission, as in Eq. 42-6.

$$(20\,\text{kilotons TNT})\left(\frac{5\times10^{12}\,\text{J}}{1\,\text{kiloton}}\right)\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right)\left(\frac{1\,\text{fission atom}}{200\,\text{MeV}}\right)\left(\frac{0.235\,\text{kg}}{6.02\times10^{23}\,\text{atom}}\right)$$

$$= 1.220\,\text{kg} \approx \boxed{1\,\text{kg}}$$

(*b*) Use $E = mc^2$.

$$E = mc^2 \rightarrow m = \frac{E}{c^2} = \frac{(20\,\text{kilotons TNT})\left(\dfrac{5\times10^{12}\,\text{J}}{1\,\text{kiloton}}\right)}{\left(3.0\times10^8\,\text{m/s}\right)^2} = 1.11\times10^{-3}\,\text{kg} \approx \boxed{1\,\text{g}}$$

This is consistent with the result found in Problem 26.

69. The effective dose (in rem) is equal to the actual dose (in rad) times the quality factor, from Eq. 42-11a.

$$\text{dose}(\text{rem}) = (29\,\text{mrad/yr X-ray, } \gamma\text{-ray})(1) + (3.6\,\text{mrad/yr})(10) = \boxed{65\,\text{mrem/yr}}$$

70. The oceans cover about 70% of the Earth, to an average depth of approximately 4 km. The density of the water is approximately $1000\,\text{kg/m}^3$. Find the volume of water using the surface area of the Earth. Then convert that volume of water to mass, to the number of water molecules, to the number of hydrogen atoms, and then finally to the number of deuterium atoms using the natural abundance of deuterium from Appendix F.

$$\text{Mass of water} = (\text{surface area})(\text{depth})(\text{density}) = 4\pi\left(6.38\times10^6\,\text{m}\right)^2(4000\,\text{m})\left(1000\,\text{kg/m}^3\right)$$

$$= 2.05\times10^{21}\,\text{kg water}$$

$$\left(2.05\times10^{21}\,\text{kg water}\right)\left(\frac{6.02\times10^{23}\,\text{molecules}}{0.018\text{ kg water}}\right)\left(\frac{2\text{ H atoms}}{1\text{ molecule}}\right)\left(\frac{0.000115\text{ d atoms}}{1\text{ H atom}}\right)$$

$$= 1.58\times10^{43}\,\text{d} \approx \boxed{2\times10^{43}\,\text{d atoms}}$$

$$= 1.58\times10^{43}\,\text{d}\left(\frac{2\times10^{-3}\,\text{kg}}{6.02\times10^{23}\,\text{d atoms}}\right) \approx \boxed{5\times10^{16}\,\text{kg d}}$$

From Eqs. 42-9a and 42-9b, if the two reactions are carried out at the same rate then 4 deuterons would produce 7.23 MeV of energy. Use that relationship to convert the number of deuterons in the oceans to energy.

$$\left(1.58\times10^{43}\,\text{d}\right)\times\frac{7.23\,\text{MeV}}{4\text{ d}}\times\frac{1.60\times10^{-13}\,\text{J}}{1\,\text{MeV}} = 4.57\times10^{30}\,\text{J} \approx \boxed{5\times10^{30}\,\text{J}}$$

71. Because the quality factor for gamma rays is 1, the dose in rem is equal in number to the dose in rad. Since the intensity falls off as r^2, the square of the distance, the exposure rate times r^2 is constant.

$$\text{Allowed dose} = \frac{5\,\text{rem}}{\text{year}}\left(\frac{1\,\text{rad}}{1\,\text{rem}}\right)\left(\frac{1\text{ year}}{52\text{ weeks}}\right)\left(\frac{1\,\text{week}}{35\,\text{hours}}\right) = 2.747\times10^{-3}\,\frac{\text{rad}}{\text{hour}}$$

$$\left(2.747\times10^{-3}\,\frac{\text{rad}}{\text{hour}}\right)r^2 = \left(5.2\times10^{-2}\,\frac{\text{rad}}{\text{hour}}\right)(1\,\text{m})^2 \quad\rightarrow$$

$$r = \sqrt{\frac{\left(5.2\times10^{-2}\,\frac{\text{rad}}{\text{hour}}\right)(1\,\text{m})^2}{\left(2.747\times10^{-3}\,\frac{\text{rad}}{\text{hour}}\right)}} = 4.351\,\text{m} \approx \boxed{4.4\,\text{m}}$$

72. (*a*) The reaction is of the form $? \rightarrow {}^4_2\text{He} + {}^{222}_{86}\text{Rn}$. There are 88 protons and 226 nucleons as products, so there must be 88 protons and 226 nucleons as reactants. Thus the parent nucleus is ${}^{226}_{88}\text{Ra}$.

$$\boxed{{}^{226}_{88}\text{Ra} \rightarrow {}^4_2\text{He} + {}^{222}_{86}\text{Rn}}$$

(*b*) If we ignore the kinetic energy of the daughter nucleus, then the kinetic energy of the alpha particle is the *Q*-value of the reaction.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$K_\alpha = m_{{}^{226}_{88}\mathrm{Ra}}c^2 - m_{{}^{4}_{2}\mathrm{He}}c^2 - m_{{}^{222}_{86}\mathrm{Rn}}c^2$$

$$= \left[226.025410\,\mathrm{u} - 4.002603\,\mathrm{u} - 222.017578\,\mathrm{u}\right]\left(931.5\frac{\mathrm{MeV}/c^2}{\mathrm{u}}\right)c^2 = \boxed{4.871\,\mathrm{MeV}}$$

(*c*) From momentum conservation, the momentum of the alpha particle will be equal in magnitude to the momentum of the daughter particle. At the energy above, the alpha particle is not relativistic, and so $K_\alpha = \dfrac{p_\alpha^2}{2m_\alpha} \rightarrow p_\alpha = \sqrt{2m_\alpha K_\alpha}$.

$$p_\alpha = \sqrt{2m_a K_a} = \sqrt{2\left(4.002603\,\mathrm{u}\right)\left(\frac{931.5\,\mathrm{MeV}/c^2}{1\,\mathrm{u}}\right)\left(4.871\,\mathrm{MeV}\right)} = \boxed{191\,\mathrm{MeV}/c}$$

(*d*) Since $p_\alpha = p_{\text{daughter}}$, $K_{\text{daughter}} = \dfrac{p_{\text{daughter}}^2}{2m_{\text{daughter}}} = \dfrac{p_\alpha^2}{2m_{\text{daughter}}}$.

$$K_{\text{daughter}} = \frac{p_\alpha^2}{2m_{\text{daughter}}} = \frac{\left(191\,\mathrm{MeV}/c\right)^2}{2\left(222\,\mathrm{u}\right)\left(\dfrac{931.5\,\mathrm{MeV}/c^2}{1\,\mathrm{u}}\right)} = \boxed{8.82\times10^{-2}\,\mathrm{MeV}}$$

Thus we see that our original assumption of ignoring the kinetic energy of the daughter nucleus is valid. The kinetic energy of the daughter is less than 2% of the *Q*-value.

73. (*a*) The mass of fuel can be found by converting the power to energy to number of nuclei to mass.

$$\left(2400\times10^6\,\mathrm{J/s}\right)\left(1\,\mathrm{y}\right)\left(\frac{3.156\times10^7\,\mathrm{s}}{1\,\mathrm{y}}\right)\left(\frac{1\,\mathrm{MeV}}{1.60\times10^{-13}\,\mathrm{J}}\right)\left(\frac{1\,\text{fission atom}}{200\,\mathrm{MeV}}\right)\left(\frac{0.235\,\mathrm{kg}}{6.02\times10^{23}\,\text{atom}}\right)$$

$$= 9.240\times10^4\,\mathrm{kg} \approx \boxed{920\,\mathrm{kg}}$$

(*b*) The product of the first 5 factors above gives the number of U atoms that fission.

$$\#\,\text{Sr atoms} = 0.06\left(2400\times10^6\,\mathrm{J/s}\right)\left(1\,\mathrm{y}\right)\left(\frac{3.156\times10^7\,\mathrm{s}}{1\,\mathrm{y}}\right)\left(\frac{1\,\mathrm{MeV}}{1.60\times10^{-13}\,\mathrm{J}}\right)\left(\frac{1\,\text{fission atom}}{200\,\mathrm{MeV}}\right)$$

$$= 1.42\times10^{26}\,\text{Sr atoms}$$

The activity is given by Eq. 41-7a.

$$\left|\frac{dN}{dt}\right| = \lambda N = \frac{\ln 2}{T_{1/2}}N = \frac{\ln 2}{\left(29\,\mathrm{yr}\right)\left(3.156\times10^7\,\mathrm{s/yr}\right)}\left(1.42\times10^{26}\right) = 1.076\times10^{17}\ \text{decays/s}$$

$$= \left(1.076\times10^{17}\ \text{decays/s}\right)\left(\frac{1\,\mathrm{Ci}}{3.70\times10^{10}\ \text{decays/s}}\right) = 2.91\times10^6\,\mathrm{Ci} \approx \boxed{3\times10^6\,\mathrm{Ci}}$$

74. This "heat of combustion" is 26.2 MeV / 4 hydrogen atoms.

$$\frac{26.2\,\mathrm{MeV}}{4\ \mathrm{H\ atoms}}\left(\frac{1.60\times10^{-13}\,\mathrm{J}}{1\,\mathrm{MeV}}\right)\left(\frac{1\,\mathrm{H\,atom}}{1.0078\,\mathrm{u}}\right)\left(\frac{1\,\mathrm{u}}{1.66\times10^{-27}\,\mathrm{kg}}\right) = \boxed{6.26\times10^{14}\,\mathrm{J/kg}}$$

This is about $\boxed{2\times10^7}$ times the heat of combustion of coal.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

75. (*a*) The energy is radiated uniformly over a sphere with a radius equal to the orbit radius of the Earth.

$$\left(1300\,\text{W/m}^2\right)4\pi\left(1.496\times10^{11}\,\text{m}\right)^2 = 3.656\times10^{26}\,\text{W} \approx \boxed{3.7\times10^{26}\,\text{W}}$$

(*b*) The reaction of Eq. 42-8 releases 26.2 MeV for every 4 protons consumed, assuming we ignore the energy carried away with the neutrinos.

$$\left(3.656\times10^{26}\,\frac{\text{J}}{\text{s}}\right)\left(\frac{4\text{ protons}}{26.2\,\text{MeV}}\right)\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right) = 3.489\times10^{38}\,\text{protons/s}$$

$$\approx \boxed{3.5\times10^{38}\,\text{protons/s}}$$

(*c*) Convert the Sun's mass to a number of protons, and then use the above result to estimate the Sun's lifetime.

$$2.0\times10^{30}\,\text{kg}\left(\frac{1\,\text{proton}}{1.673\times10^{-27}\,\text{kg}}\right)\left(\frac{1\,\text{s}}{3.489\times10^{38}\,\text{protons}}\right)\left(\frac{1\,\text{yr}}{3.156\times10^{7}}\right) \approx \boxed{1.1\times10^{11}\,\text{yr}}$$

76. For the net proton cycle, Eq. 42-8, we see that there are two neutrinos produced for every four protons consumed. Thus the net number of neutrinos generated per second from the sun is just half the value of protons consumed per second. That proton consumption rate is calculated in Problem 75b.

$$\left(3.489\times10^{38}\,\text{protons/s}\right)\left(\frac{2\,\nu}{4\,\text{p}}\right) = 1.745\times10^{38}\,\nu/\text{s}$$

We assume the neutrinos are spread out uniformly over a sphere centered at the Sun. So the fraction that would pass through the area of the ceiling can be found by a ratio of areas, assuming the ceiling is perpendicular to the neutrino flux. But since the window is not perpendicular, a cosine factor is included to account for the angle difference, as discussed in Eq. 22-1a. Finally, we adjust for the one-hour duration, assuming the relative angle is constant over that hour.

$$\left(1.745\times10^{38}\,\nu/\text{s}\right)\frac{180\,\text{m}^2}{4\pi\left(1.496\times10^{11}\,\text{m}\right)^2}\left(\cos38°\right)\left(3600\,\text{s}\right) = \boxed{3.2\times10^{20}\,\nu}$$

77. We use the common value of 200 MeV of energy released per fission. We then multiply that by the number of fissions, which we take as 5.0% of the number of U-238 atoms.

$$\text{Total energy} = \left[\frac{200\,\text{MeV}}{1\text{ nucleus of }{}^{235}_{92}\text{U}}\left(\frac{1.602\times10^{-13}\,\text{J}}{1\,\text{MeV}}\right)\left(0.05\,\frac{{}^{235}_{92}\text{U nuclei}}{{}^{238}_{92}\text{U nuclei}}\right)\left(2.0\,\text{kg}\,{}^{238}_{92}\text{U}\right)\right.$$
$$\left.\times\left(\frac{6.022\times10^{23}\text{ nuclei of }{}^{238}_{92}\text{U nuclei}}{0.238\,\text{kg}\,{}^{238}_{92}\text{U}}\right)\right]$$
$$= 8.107\times10^{12}\,\text{J} \approx \boxed{8\times10^{12}\,\text{J}}$$

78. (*a*) The energy released is given by the *Q*-value.

$$Q = 2m_{{}^{12}_{6}\text{C}}c^2 - m_{{}^{24}_{12}\text{Mg}}c^2 = \left[2\left(12.000000\,\text{u}\right) - 23.985042\,\text{u}\right]\left(931.5\,\frac{\text{MeV}/c^2}{\text{u}}\right)c^2 = \boxed{13.93\,\text{MeV}}$$

(*b*) The total kinetic energy of the two nuclei must equal their potential energy when separated by 6.0 fm.

$$2K = \frac{1}{4\pi\varepsilon_0}\frac{q_1q_2}{r} \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$K = \tfrac{1}{2}\frac{1}{4\pi\varepsilon_0}\frac{q_1 q_2}{r} = \tfrac{1}{2}\left(8.99\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\frac{\left[(6)\left(1.60\times10^{-19}\,\text{C}\right)\right]^2}{6.0\times10^{-15}\,\text{m}}\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right)$$

$$= 4.315\,\text{MeV} \approx \boxed{4.3\,\text{MeV}}$$

(*c*) The kinetic energy and temperature are related by Eq. 18-4.

$$K = \tfrac{3}{2}kT \quad\rightarrow\quad T = \tfrac{2}{3}\frac{K}{k} = \tfrac{2}{3}\frac{\left(4.315\,\text{MeV}\right)\left(\dfrac{1.60\times10^{-13}\,\text{J}}{1\,\text{MeV}}\right)}{1.38\times10^{-23}\,\text{J/K}} = \boxed{3.3\times10^{10}\,\text{K}}$$

79. (*a*) A Curie is 3.7×10^{10} decays/s.

$$\left(0.10\times10^{-6}\,\text{Ci}\right)\left(3.7\times10^{10}\ \text{decays/s}\right) = \boxed{3700\,\text{decays/s}}$$

(*b*) The beta particles have a quality factor of 1. We calculate the dose in gray and then convert to sieverts. The half life is over a billion years, so we assume the activity is constant.

$$\left(3700\,\text{decays/s}\right)\left(1.4\,\text{MeV/decay}\right)\left(1.60\times10^{-13}\,\text{J/MeV}\right)\left(3.156\times10^{7}\,\text{s/y}\right)\left(\frac{1}{55\,\text{kg}}\right)$$

$$= 4.756\times10^{-4}\,\text{J/kg/y} = 4.756\times10^{-4}\,\text{Gy/y} = \boxed{4.8\times10^{-4}\,\text{Sv/y}}$$

This is about $\dfrac{4.756\times10^{-4}\,\text{Sv/y}}{3.6\times10^{-3}\,\text{Sv/y}} = 0.13$ or $\boxed{13\%\text{ of the background rate}}$.

80. The surface area of a sphere is $4\pi r^2$.

$$\frac{\text{Activity}}{\text{m}^2} = \frac{2.0\times10^{7}\,\text{Ci}}{4\pi r_{\text{Earth}}^2} = \frac{\left(2.0\times10^{7}\,\text{Ci}\right)\left(3.7\times10^{10}\ \text{decays/s}\right)}{4\pi\left(6.38\times10^{6}\,\text{m}\right)^2} = \boxed{1400\,\frac{\text{decays/s}}{\text{m}^2}}$$

81. $$Q = 3m_{{}^4_2\text{He}}c^2 - m_{{}^{12}_6\text{C}}c^2 = \left[3\left(4.002603\,\text{u}\right) - 12.000000\,\text{u}\right]\left(931.5\,\frac{\text{MeV}/c^2}{\text{u}}\right)c^2 = \boxed{7.274\,\text{MeV}}$$

82. Since the half-life is 30 years, we assume that the activity does not change during the 2.0 hours of exposure. We calculate the total energy absorbed, and then calculate the effective dose. The two energies can be added directly since the quality factor for both gammas and betas is about 1.

$$\text{Energy} = \left[\begin{array}{l}\left(1.2\times10^{-6}\,\text{Ci}\right)\left(3.7\times10^{10}\,\dfrac{\text{decays}}{\text{s}}\right)\left(1.6\,\text{hr}\right)\left(3600\,\dfrac{\text{s}}{1\,\text{hr}}\right)\times \\ \left(850\times10^{3}\,\dfrac{\text{eV}}{\text{decay}}\right)\left(1.60\times10^{-19}\,\dfrac{\text{J}}{\text{eV}}\right)\end{array}\right] = 3.478\times10^{-5}\,\text{J}$$

$$\text{dose} = \frac{3.478\times10^{-5}\,\text{J}}{65\,\text{kg}}\times\frac{100\,\text{rad}}{1\,\text{J/kg}} = 5.351\times10^{-5}\,\text{rad} \approx \boxed{5.4\times10^{-5}\,\text{rem}}$$

83. The half life of the strontium isotope is 28.79 years. Use that with Eq. 41-7c to find the time for the activity to be reduced to 15% of its initial value.

$$R = R_0 e^{-\lambda t} \quad\rightarrow\quad t = -\frac{1}{\lambda}\ln\frac{R}{R_0} = -\frac{T_{1/2}}{\ln 2}\ln\frac{R}{R_0} = -\frac{\left(28.79\,\text{y}\right)\ln\left(0.15\right)}{\ln 2} \approx \boxed{79\,\text{y}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

84. Source B is more dangerous than source A because of its higher energy. Since both sources have the same activity, they both emit the same number of gammas. Source B can deposit twice as much energy per gamma and therefore cause more biological damage.

Source C is more dangerous than source B because the alphas have a quality factor up to 20 times larger than the gammas. Thus a number of alphas may have an effective dose up to 20 times higher than the effective dose of the same number of like-energy gammas.

So from most dangerous to least dangerous, the ranking of the sources is $\boxed{\text{C} > \text{B} > \text{A}}$.

We might say that source B is twice as dangerous as source A, and source C is 20 times more dangerous than source B.

85. The whole-body dose can be converted into a number of decays, which would be the maximum number of nuclei that could be in the Tc sample. The quality factor of gammas is 1.

$$50\,\text{mrem} = 50\,\text{mrad} \;\rightarrow\; \left(50\times10^{-3}\,\text{rad}\right)\left(\frac{1\,\text{J/kg}}{100\,\text{rad}}\right)(60\,\text{kg})\left(\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}}\right) = 1.875\times10^{17}\,\text{eV}$$

$$\left(1.875\times10^{17}\,\text{eV}\right)\left(\frac{1\text{ effective }\gamma}{140\times10^{3}\,\text{eV}}\right)\left(\frac{2\,\gamma\text{ decays}}{1\text{ effective }\gamma}\right)\left(\frac{1\text{ nucleus}}{1\,\gamma\text{ decay}}\right) = 2.679\times10^{12}\,\text{nuclei}$$

This is the total number of decays that will occur. The activity for this number of nuclei can be calculated from Eq. 41-7a.

$$R = \lambda N = \frac{\ln 2}{T_{1/2}}N = \frac{\ln 2\left(2.67910^{12}\,\text{decays}\right)}{(6\,\text{h})(3600\,\text{s/h})}\left(\frac{1\,\text{Ci}}{3.70\times10^{10}\,\text{decays/s}}\right) \approx 2.32\times10^{-3}\,\text{Ci} \approx \boxed{2\,\text{mCi}}$$

86. The number of $^{60}_{27}\text{Co}$ nuclei (N_{60}) can be calculated from the activity and the half-life of $^{60}_{27}\text{Co}$. The number of $^{60}_{27}\text{Co}$ nuclei can also be calculated from the cross section and the number of $^{59}_{27}\text{Co}$ nuclei (N_{59}) present in the paint. By combining these two calculations, we can find the number of $^{59}_{27}\text{Co}$ in the paint. We assume that, since the half life is relatively long, that all $^{60}_{27}\text{Co}$ are made initially, without any of them decaying.

$$\left|\frac{dN_{60}}{dt}\right| = \lambda N_{60} = \frac{\ln 2}{T_{1/2}}N_{60} \;\rightarrow\; N_{60} = \left|\frac{dN_{60}}{dt}\right|\frac{T_{1/2}}{\ln 2}$$

We assume the paint is thin and so use Eq. 42-3 for the cross section. Let *R* represent the rate at which $^{60}_{27}\text{Co}$ nuclei are made (i.e., the collision rate), and *t* the elapsed time of neutron bombardment. R_0 is the rate at which the neutrons hit the painting, and so is the given neutron flux times the area of the painting.

$$N_{60} = Rt = R_0 n\ell\sigma t = R_0\left(\frac{N_{59}}{\text{volume of paint}}\right)\left(\frac{\text{volume of paint}}{\text{surface area of paint}}\right)\sigma t = \frac{R_0 N_{59}\sigma t}{A}$$

$$= \frac{(\text{neutron flux})AN_{59}\sigma t}{A} = (\text{neutron flux})N_{59}\sigma t \;\rightarrow$$

$$N_{59} = \frac{N_{60}}{(\text{neutron flux})\sigma t} = \left|\frac{dN_{60}}{dt}\right|\frac{T_{1/2}}{\ln 2(\text{neutron flux})\sigma t}$$

$$= (55\,\text{decays/s})\frac{(5.27\,\text{yr})(3.156\times10^{7}\,\text{s/yr})}{(\ln 2)\left(\dfrac{5.0\times10^{12}}{\text{cm}^2\bullet\text{s}}\right)\left(10^4\,\dfrac{\text{cm}^2}{\text{m}^2}\right)(19\times10^{-28}\,\text{m}^2)(300\,\text{s})}$$

$$= 4.631\times10^{17}\,\text{atoms} \;\rightarrow\; m_{59} = (4.631\times10^{17}\,\text{atoms})\left(\frac{58.933\,\text{g}}{6.022\times10^{23}\,\text{atoms}}\right) = \boxed{4.5\times10^{-5}\,\text{g}}$$

87. Since all speeds are relativistic, we may use $p = \sqrt{2mK}$ to relate momentum and kinetic energy. If we assume the target is at rest, then the total momentum of the products must equal the momentum of the bombarding particle. The total (kinetic) energy of the products comes from the kinetic energy of the bombarding particle and the *Q*-value of the reaction.

$$p_{\text{pr}} = p_{\text{b}} \;\rightarrow\; \sqrt{2m_{\text{pr}}K_{\text{pr}}} = \sqrt{2m_{\text{b}}K_{\text{br}}} \;\rightarrow\; K_{\text{pr}} = \frac{m_{\text{b}}}{m_{\text{pr}}}K_{\text{b}} = Q + K_{\text{b}} \;\rightarrow\; \boxed{K_{\text{b}} = -\frac{Qm_{\text{pr}}}{m_{\text{pr}} - m_{\text{b}}}}$$

88. (*a*) We assume a thin target, and use Eq. 42-3.

$$\sigma = \frac{R}{R_0 n\ell} = \frac{R}{R_0}\frac{1}{n\ell} = (1.6\times10^{-5})\frac{1}{(5.9\times10^{28}\,\text{m}^{-3})(4.0\times10^{-7}\,\text{m})}\left(\frac{1\,\text{bn}}{10^{-28}\,\text{m}^2}\right) = \boxed{6.8\,\text{bn}}$$

(*b*) We assume that the cross section is the area presented by the gold nucleus.

$$\sigma = \pi r^2 = \tfrac{1}{4}\pi d^2 \;\rightarrow\; d = \sqrt{\frac{4(6.8\,\text{bn})}{\pi}} = \left(\frac{1\,\text{bn}}{10^{-28}\,\text{m}^2}\right) = \boxed{2.9\times10^{-14}\,\text{m}}$$

CHAPTER 43: Elementary Particles

Responses to Questions

1. $p + n \rightarrow p + p + \pi^-$.

2. No. In the rest frame of the proton, this decay is energetically impossible, and so it is impossible in every other frame as well. In a frame in which the proton is moving very fast, the decay products must be moving very fast as well to conserve momentum. With this constraint, there will not be enough energy to make the decay possible.

3. "Antiatoms" would be made up of antiprotons, antineutrons, and positrons. If antimatter came into contact with matter, the corresponding pairs of particles would annihilate, producing energy in the form of gamma rays and other particles.

4. The photon signals the electromagnetic interaction.

5. (*a*) Yes, if a neutrino is produced during a decay, the weak interaction is responsible.
(*b*) No, for example, a weak interaction decay could produce a Z^0 instead of a neutrino.

6. The neutron decay process also produces an electron and an antineutrino; these two particles only interact via the weak force. In addition, the strong force dominates at extremely small distances and at other distances the weak force dominates.

7. An electron takes part in electromagnetic, weak, and gravitational interactions. A neutrino takes part in weak and gravitational interactions. A proton takes part in all four interactions: strong, electromagnetic, weak, and gravitational.

8. All of the gauge bosons, leptons, and mesons have baryon number equal to zero and there are no baryons produced in the decays, so baryon number is conserved for these groups. The chart below shows charge conservation for a few examples of decays in these groups.

Particle name	Decay	Charge conservation check
W	$W^+ \rightarrow e^+ + \nu_e$	+1 = +1 + 0
muon	$\mu^- \rightarrow e^- + \bar{\nu}_e + \nu_\mu$	–1 = –1 + 0 + 0
tau	$\tau^- \rightarrow \mu^- + \bar{\nu}_\mu + \nu_\tau$ $\tau^- \rightarrow e^- + \bar{\nu}_e + \nu_\tau$	–1 = –1 + 0 + 0 –1 = –1 + 0 + 0
pion	$\pi^+ \rightarrow \mu^+ + \nu_\mu$	+1 = +1 + 0
eta	$\eta^0 \rightarrow 3\pi^o$ $\eta^0 \rightarrow \pi^+ + \pi^- + \pi^0$	0 = 0 + 0 + 0 0 = +1 –1 + 0

The next chart shows charge conservation and baryon number conservation for a sample of the baryon decays shown in Table 43-2.

Particle name	Decay	Charge conservation check	Baryon number (*B*) conservation check
neutron	$n \rightarrow p + e^- + \bar{\nu}_e$	0 = +1 –1 + 0	+1 = +1 + 0 + 0

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

sigma	$\Sigma^+ \rightarrow p + \pi^o$ $\Sigma^+ \rightarrow n + \pi^+$	+1 = +1 + 0 +1 = 0 + 1	+1 = +1 + 0 +1 = +1 + 0

9. Decays via the electromagnetic interaction are indicated by the production of photons. In Table 43-2, the decays of π^0, Σ^0, and η^0 proceed via the electromagnetic interaction.

10. All of the decays listed in Table 43-2 in which a neutrino or antineutrino is one of the decay products occur via the weak interaction. These include the W, muon, tau, pion, kaon, and neutron. In addition, the Z particle decays via the weak interaction.

11. The Δ baryon has a baryon number of one and is therefore made of three quarks. The u, c, and t quarks have a charge of +2/3 *e* each and the d, s, and b quarks have a charge of -1/3 *e* each. There is no way to combine three quarks for a total charge of -2*e*.

12. As evidenced by their shorter lifetimes, the J/ψ and Y particles decay via the electromagnetic interaction.

13. Based on the lifetimes listed, all of the particles in Table 43-4, except the J/ψ and the Y, decay via the weak interaction.

14. Baryons are formed from three quarks or antiquarks, each of spin $\frac{1}{2}$ or $-\frac{1}{2}$, respectively. Any combination of quarks and antiquarks will yield a spin magnitude of either $\frac{1}{2}$ or $\frac{3}{2}$. Mesons are formed from two quarks or antiquarks. Any combination of two quarks or antiquarks will yield a spin magnitude of either 0 or 1.

15. The "neutrinolet" would not interact via the gravitational force (no mass), the strong force (no color charge), or the electromagnetic force (no electrical charge). In addition, it does not feel the weak force. However, it could possibly exist. The photon, for example, also has no rest mass, color charge, or electric charge and does not feel the weak force.

16. (*a*) No. Leptons are fundamental particles with no known internal structure. Baryons are made up of three quarks.
(*b*) Yes. All baryons are hadrons.
(*c*) No. A meson is a quark–antiquark pair.
(*d*) No. Hadrons are made up of quarks and leptons are fundamental particles.

17. No. A particle made up of two quarks would have a particular color. Three quarks or a quark–antiquark pair are necessary for the particle to be white or colorless. A combination of two quarks and two antiquarks is possible, as the resulting particle could be white or colorless.

18. Inside the nucleus, a neutron will not decay because the dominant interaction is the strong interaction with the other nucleons. A free neutron will decay through the weak interaction.

19. The reaction is not possible, because it does not conserve lepton number. L = 1 on the left-hand side of the reaction equation, and L = –1 on the right-hand side of the reaction equation.

20. The reaction proceeds by the weak force. We know this because an electron anti-neutrino is produced in the reaction, which only happens in reactions governed by the weak interaction.

Solutions to Problems

1. The total energy is given by Eq. 36-11a.

$$E = m_0c^2 + K = 0.938\,\text{GeV} + 4.65\text{GeV} = \boxed{5.59\,\text{GeV}}$$

2. Because the energy of the electrons is much greater than their rest mass, we have $K = E = pc$. Combine that with Eq. 43-1 for the de Broglie wavelength.

$$E = pc\ ;\ p = \frac{h}{\lambda} \ \rightarrow\ E = \frac{hc}{\lambda} \ \rightarrow\ \lambda = \frac{hc}{E} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(28\times10^{9}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = \boxed{4.4\times10^{-17}\,\text{m}}$$

3. The frequency is related to the magnetic field in Eq. 43-2.

$$f = \frac{qB}{2\pi m} \ \rightarrow\ B = \frac{2\pi mf}{q} = \frac{2\pi\left(1.67\times10^{-27}\,\text{kg}\right)\left(3.1\times10^{7}\,\text{Hz}\right)}{1.60\times10^{-19}\,\text{C}} = \boxed{2.0\,\text{T}}$$

4. The time for one revolution is the period of revolution, which is the circumference of the orbit divided by the speed of the protons. Since the protons have very high energy, their speed is essentially the speed of light.

$$T = \frac{2\pi r}{v} = \frac{2\pi\left(1.0\times10^{3}\,\text{m}\right)}{3.0\times10^{8}\,\text{m/s}} = \boxed{2.1\times10^{-5}\,\text{s}}$$

5. Use Eq. 43-2 to calculate the frequency. The alpha particle has a charge of +2*e* and a mass of 4 times the proton mass.

$$f = \frac{qB}{2\pi m} = \frac{2\left(1.60\times10^{-19}\,\text{C}\right)\left(1.7\,\text{T}\right)}{2\pi\left[4\left(1.67\times10^{-27}\,\text{kg}\right)\right]} = \boxed{1.3\times10^{7}\,\text{Hz}} = 13\,\text{MHz}$$

6. (*a*) The maximum kinetic energy is $K = \dfrac{q^2B^2R^2}{2m} = \frac{1}{2}mv^2$. Compared to Example 43-2, the charge has been doubled and the mass has been multiplied by 4. These two effects cancel each other in the equation, and so the maximum kinetic energy is unchanged. The kinetic energy from that example was 8.653 MeV.

$$K = \boxed{8.7\,\text{MeV}}$$

$$v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2\left(8.653\,\text{MeV}\right)\left(1.60\times10^{-13}\,\text{J/MeV}\right)}{4\left(1.66\times10^{-27}\,\text{kg}\right)}} = 2.042\times10^{7}\,\text{m/s} \approx \boxed{2.0\times10^{7}\,\text{m/s}}$$

(*b*) The maximum kinetic energy is $K = \dfrac{q^2B^2R^2}{2m} = \frac{1}{2}mv^2$. Compared to Example 43-2, the charge is unchanged and the mass has been multiplied by 2. Thus the kinetic energy will be half of what it was in Example 43-2 (8.653 MeV).

$$K = \boxed{4.3\,\text{MeV}}$$

$$v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2\left[\frac{1}{2}\left(8.653\,\text{MeV}\right)\right]\left(1.60\times10^{-13}\,\text{J/MeV}\right)}{2\left(1.66\times10^{-27}\,\text{kg}\right)}} = 2.042\times10^{7}\,\text{m/s} \approx \boxed{2.0\times10^{7}\,\text{m/s}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

The alpha and the deuteron have the same charge to mass ratio, and so move at the same speed.

(*c*) The frequency is given by $f = \dfrac{qB}{2\pi m}$. Since the charge to mass ratio of both the alpha and the deuteron is half that of the proton, the frequency for the alpha and the deuteron will both be half the frequency found in Example 43-2 for the proton.

$$\boxed{f = 13\,\text{MHz}}$$

7. From Eq. 41-1, the diameter of a nucleon is about $d_{\text{nucleon}} = 2.4\times10^{-15}\,\text{m}$. The 25-MeV alpha particles and protons are not relativistic, so their momentum is given by $p = mv = \sqrt{2mK}$. The wavelength is given by Eq. 43-1, $\lambda = \dfrac{h}{p} = \dfrac{h}{\sqrt{2mK}}$.

$$\lambda_\alpha = \frac{h}{\sqrt{2m_\alpha \text{KE}}} = \frac{6.63\times10^{-34}\,\text{J}\cdot\text{s}}{\sqrt{2(4)\left(1.66\times10^{-27}\,\text{kg}\right)\left(25\times10^{6}\,\text{eV}\right)\left(1.6\times10^{-19}\,\text{J/eV}\right)}} = 2.88\times10^{-15}\,\text{m}$$

$$\lambda_\text{p} = \frac{h}{\sqrt{2m_\text{p}\text{KE}}} = \frac{6.63\times10^{-34}\,\text{J}\cdot\text{s}}{\sqrt{2\left(1.67\times10^{-27}\,\text{kg}\right)\left(25\times10^{6}\,\text{eV}\right)\left(1.6\times10^{-19}\,\text{J/eV}\right)}} = 5.75\times10^{-15}$$

We see that $\boxed{\lambda_\alpha \approx d_{\text{nucleon}}}$ and $\boxed{\lambda_\text{p} \approx 2d_{\text{nucleon}}}$. Thus the alpha particle will be better for picking out details in the nucleus.

8. Because the energy of the protons is much greater than their rest mass, we have $K = E = pc$. Combine this with the expression (given above Example 43-2) relating the momentum and radius of curvature for a particle in a magnetic field.

$$v = \frac{qBr}{m} \;\rightarrow\; mv = qBr \;\rightarrow\; p = qBr \;\rightarrow\; \frac{E}{c} = qBr \;\rightarrow$$

$$B = \frac{E}{qrc} = \frac{\left(1.0\times10^{12}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}{\left(1.60\times10^{-19}\,\text{C}\right)\left(1.0\times10^{3}\,\text{m}\right)\left(3.00\times10^{8}\,\text{m/s}\right)} = \boxed{3.3\,\text{T}}$$

9. Because the energy of the protons is much greater than their rest mass, we have $K = E = pc$. A relationship for the magnetic field is given right before Eq. 43-2.

$$v = \frac{qBr}{m} \;\rightarrow\; mv = qBr \;\rightarrow\; p = qBr \;\rightarrow\; \frac{E}{c} = qBr \;\rightarrow$$

$$B = \frac{E}{qrc} = \frac{\left(7.0\times10^{15}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}{\left(1.60\times10^{-19}\,\text{C}\right)\left(4.25\times10^{3}\,\text{m}\right)\left(3.00\times10^{8}\,\text{m/s}\right)} = \boxed{5.5\,\text{T}}$$

10. (*a*) The magnetic field is found from the maximum kinetic energy as derived in Example 43-2.

$$K = \frac{q^2B^2R^2}{2m} \;\rightarrow\; B = \frac{\sqrt{2mK}}{qR} \;\rightarrow$$

$$B = \frac{\sqrt{2(2.014)\left(1.66\times10^{-27}\,\text{kg}\right)\left(12\times10^{6}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}}{\left(1.60\times10^{-19}\,\text{C}\right)(1.0\,\text{m})} = 0.7082\,\text{T} \approx \boxed{0.71\,\text{T}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) The cyclotron frequency is given by Eq. 43-2.

$$f = \frac{qB}{2\pi m} = \frac{\left(1.60\times10^{-19}\,\text{C}\right)\left(0.7082\,\text{T}\right)}{2\pi\left(2.014\right)\left(1.66\times10^{-27}\,\text{kg}\right)} = 5.394\times10^{6}\,\text{Hz} \approx \boxed{5.4\,\text{MHz}}$$

(*c*) The deuteron will be accelerated twice per revolution, and so will gain energy equal to twice its charge times the voltage on each revolution.

$$\text{number of revolutions} = n = \frac{12\times10^{6}\,\text{eV}}{2\left(1.60\times10^{-19}\,\text{C}\right)\left(22\times10^{3}\,\text{V}\right)}\left(1.60\times10^{-19}\,\text{J/eV}\right)$$

$$= 273 \text{ revolutions} \approx \boxed{270 \text{ revolutions}}$$

(*d*) The time is the number of revolutions divided by the frequency (which is revolutions per second).

$$\Delta t = \frac{n}{f} = \frac{273\,\text{revolutions}}{5.394\times10^{6}\,\text{rev/s}} = \boxed{5.1\times10^{-6}\,\text{s}} = 51\mu\text{s}$$

(*e*) If we use an average radius of half the radius of the cyclotron, then the distance traveled is the average circumference times the number of revolutions.

$$\text{distance} = \tfrac{1}{2}2\pi rn = \pi\left(1.0\,\text{m}\right)\left(273\right) = \boxed{860\,\text{m}}$$

11. Because the energy of the protons is much greater than their rest mass, we have $K = E = pc$. Combine that with Eq. 43-1 for the de Broglie wavelength. That is the minimum size that protons of that energy could resolve.

$$E = pc\ ;\ p = \frac{h}{\lambda} \ \rightarrow\ E = \frac{hc}{\lambda} \ \rightarrow\ \lambda = \frac{hc}{E} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.0\times10^{8}\,\text{m/s}\right)}{\left(7.0\times10^{12}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = \boxed{1.8\times10^{-19}\,\text{m}}$$

12. If the speed of the protons is *c*, then the time for one revolution is found from uniform circular motion. The number of revolutions is the total time divided by the time for one revolution. The energy per revolution is the total energy gained divided by the number of revolutions.

$$v = \frac{2\pi r}{T} \ \rightarrow\ T = \frac{2\pi r}{v} = \frac{2\pi r}{c} \qquad n = \frac{t}{T} = \frac{ct}{2\pi r}$$

$$\text{Energy/revolution} = \frac{\Delta E}{n} = \frac{\left(\Delta E\right)2\pi r}{ct} = \frac{\left(1.0\times10^{6}\,\text{MeV} - 150\times10^{3}\,\text{MeV}\right)2\pi\left(1.0\times10^{3}\,\text{m}\right)}{\left(3.00\times10^{8}\,\text{m/s}\right)\left(20\,\text{s}\right)}$$

$$= 0.89\,\text{MeV/rev} \approx \boxed{0.9\,\text{MeV/rev}}$$

13. Start with an expression from Section 42-1, relating the momentum and radius of curvature for a particle in a magnetic field, with *q* replaced by *e*.

$$v = \frac{eBr}{m} \ \rightarrow\ mv = eBr \ \rightarrow\ p = eBr$$

In the relativistic limit, $p = E/c$ and so $\frac{E}{c} = eBr$. To put the energy in electron volts, divide the energy by the charge of the object.

$$\frac{E}{c} = eBr \ \rightarrow\ \boxed{\frac{E}{e} = Brc}$$

14. The energy released is the difference in the mass energy between the products and the reactant.

$$\Delta E = m_{\Lambda^0}c^2 - m_n c^2 - m_{\pi^0}c^2 = 1115.7\,\text{MeV} - 939.6\,\text{MeV} - 135.0\,\text{MeV} = \boxed{41.1\,\text{MeV}}$$

15. The energy released is the difference in the mass energy between the products and the reactant.

$$\Delta E = m_{\pi^+}c^2 - m_{\mu^+}c^2 - m_{\nu_\mu}c^2 = 139.6\,\text{MeV} - 105.7\,\text{MeV} - 0 = \boxed{33.9\,\text{MeV}}$$

16. Use Eq. 43-3 to estimate the range of the force based on the mass of the mediating particle.

$$mc^2 \approx \frac{hc}{2\pi d} \quad \rightarrow \quad d \approx \frac{hc}{2\pi mc^2} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{2\pi\left(497.7\times10^{6}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} \approx \boxed{3.98\times10^{-16}\,\text{m}}$$

17. The energy required is the mass energy of the two particles.

$$E = 2m_n c^2 = 2\left(939.6\,\text{MeV}\right) = \boxed{1879.2\,\text{MeV}}$$

18. The reaction is multi-step, and can be written as shown here: $\Sigma^0 \rightarrow \Lambda^0 + \gamma$
The energy released is the initial rest energy minus the final rest energy of the proton and pion, using Table 43-2. $\downarrow\rightarrow p + \pi^-$

$$\Delta E = \left(m_{\Sigma^0} - m_{\text{p}} - m_{\pi^-}\right)c^2 = 1192.6\,\text{Mev} - 938.3\,\text{MeV} - 139.6\,\text{MeV} = \boxed{114.7\,\text{MeV}}$$

19. Because the two protons are heading towards each other with the same speed, the total momentum of the system is 0. The minimum kinetic energy for the collision would result in all three particles at rest, and so the minimum kinetic energy of the collision must be equal to the mass energy of the π^0. Each proton will have half of that kinetic energy. From Table 43-2, the mass of the π^0 is $135.0\,\text{MeV}/c^2$.

$$2K_{\text{proton}} = m_{\pi^0}c^2 = 135.0\,\text{MeV} \quad \rightarrow \quad K_{\text{proton}} = \boxed{67.5\,\text{MeV}}$$

20. Because the two neutrons are heading towards each other with the same speed, the total momentum of the system is 0. The minimum kinetic energy for the collision would result in all four particles at rest, and so the minimum kinetic energy of the collision must be equal to the mass energy of the K^+K^- pair. Each neutron will have half of that kinetic energy. From Table 43-2, the mass of each of the K^+ and the K^- is $493.7\,\text{MeV}/c^2$.

$$2K_{\text{neutron}} = 2m_{\text{K}}c^2 \quad \rightarrow \quad K_{\text{neutron}} = m_{\text{K}}c^2 = \boxed{493.7\,\text{MeV}}$$

21. We treat the neutrino as massless, but it still has momentum and energy. We use conservation of momentum and conservation of energy, along with Eqs. 36-11 and 36-13.
(*a*) To find the maximum kinetic energy of the positron, we assume that the pion has no kinetic energy, and so the magnitude of the momenta of the positron and the neutrino are the same.

$$p_{\text{e}} = p_\nu \ ;$$

$$m_{\text{K}}c^2 = m_\pi c^2 + E_{\text{e}} + E_\nu \quad \rightarrow \quad \left(m_{\text{K}}c^2 - m_\pi c^2 - E_{\text{e}}\right)^2 = E_\nu^2 = p_\nu^2 c^2 = p_{\text{e}}^2 c^2 = E_{\text{e}}^2 - m_{\text{e}}^2 c^4 \quad \rightarrow$$

$$E_{\text{e}} = \frac{\left(m_{\text{K}}c^2 - m_\pi c^2\right)^2 + m_{\text{e}}^2 c^4}{2\left(m_{\text{K}}c^2 - m_\pi c^2\right)} = K_{\text{e}} + m_{\text{e}}c^2 \quad \rightarrow$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$K_e = \frac{\left(m_K c^2 - m_\pi c^2\right)^2 + m_e^2 c^4}{2\left(m_K c^2 - m_\pi c^2\right)} - m_e c^2$$

$$= \frac{\left(497.7\,\text{MeV} - 139.6\,\text{MeV}\right)^2 + \left(0.511\,\text{MeV}\right)^2}{2\left(497.7\,\text{MeV} - 139.6\,\text{MeV}\right)} - \left(0.511\,\text{MeV}\right) = \boxed{178.5\,\text{MeV}}$$

(*b*) To find the maximum kinetic energy of the pion, we assume that the positron has no kinetic energy, and so the magnitude of the momenta of the positron and the neutrino are the same. The result is found by just interchanging the pion and positron.

$$K_e = \frac{\left(m_K c^2 - m_e c^2\right)^2 + m_\pi^2 c^4}{2\left(m_K c^2 - m_e c^2\right)} - m_\pi c^2$$

$$= \frac{\left(497.7\,\text{MeV} - 0.511\,\text{MeV}\right)^2 + \left(139.6\,\text{MeV}\right)^2}{2\left(497.7\,\text{MeV} - 0.511\,\text{MeV}\right)} - \left(139.6\,\text{MeV}\right) = \boxed{128.6\,\text{MeV}}$$

22. The energy of the two photons (assumed to be equal so that momentum is conserved) must be the combined rest mass energy of the proton and antiproton.

$$2m_0 c^2 = 2hf = 2h\frac{c}{\lambda} \quad \rightarrow \quad \lambda = \frac{hc}{m_0 c^2} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.00\times10^8\,\text{m/s}\right)}{\left(938.3\times10^6\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = \boxed{1.32\times10^{-15}\,\text{m}}$$

23. (*a*) $\Lambda^0 \rightarrow \text{n} + \pi^-$ Charge conservation is violated, since $0 \neq 0 - 1$
Strangeness is violated, since $-1 \neq 0 + 0$

(*b*) $\Lambda^0 \rightarrow \text{p} + \text{K}^-$ Energy conservation is violated, since
$1115.7\,\text{MeV}/c^2 < 938.3\,\text{MeV}/c^2 + 493.7\,\text{MeV}/c^2 = 1432.0\,\text{MeV}/c^2$

(*c*) $\Lambda^0 \rightarrow \pi^+ + \pi^-$ Baryon number conservation is violated, since $1 \neq 0 + 0$
Strangeness is violated, since $-1 \neq 0 + 0$
Spin is violated, since $\frac{1}{2} \neq 0 + 0$

24. (*a*) The *Q*-value is the mass energy of the reactants minus the mass energy of the products.

$$Q = m_{\Lambda^0} c^2 - \left(m_p c^2 + m_{\pi^-} c^2\right) = 1115.7\,\text{MeV} - \left(938.3\,\text{MeV} + 139.6\,\text{MeV}\right) = \boxed{37.8\,\text{MeV}}$$

(*b*) Energy conservation for the decay gives the following.

$$m_{\Lambda^0} c^2 = E_p + E_{\pi^-} \quad \rightarrow \quad E_{\pi^-} = m_{\Lambda^0} c^2 - E_p$$

Momentum conservation says that the magnitudes of the momenta of the two products are equal. Then convert that relationship to energy using $E^2 = p^2 c^2 + m_0^2 c^4$, with energy conservation.

$$p_p = p_{\pi^-} \quad \rightarrow \quad \left(p_p c\right)^2 = \left(p_{\pi^-} c\right)^2 \quad \rightarrow$$

$$E_p^2 - m_p^2 c^4 = E_{\pi^-}^2 - m_{\pi^-}^2 c^4 = \left(m_{\Lambda^0} c^2 - E_p\right)^2 - m_{\pi^-}^2 c^4$$

$$E_p^2 - m_p^2 c^4 = \left(m_{\Lambda^0}^2 c^4 - 2E_p m_{\Lambda^0} c^2 + E_p^2\right) - m_{\pi^-}^2 c^4 \quad \rightarrow$$

$$E_p = \frac{m_{\Lambda^0}^2 c^4 + m_p^2 c^4 - m_{\pi^-}^2 c^4}{2m_{\Lambda^0} c^2} = \frac{\left(1115.7\,\text{MeV}\right)^2 + \left(938.3\,\text{MeV}\right)^2 - \left(139.6\,\text{MeV}\right)^2}{2\left(1115.7\,\text{MeV}\right)} = 943.7\,\text{MeV}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$E_{\pi^-} = m_{\Lambda^0}c^2 - E_{\text{p}} = 1115.7\,\text{MeV} - 943.7\,\text{MeV} = 172.0\,\text{MeV}$$

$$K_{\text{p}} = E_{\text{p}} - m_{\text{p}}c^2 = 943.7\,\text{MeV} - 938.3\,\text{MeV} = \boxed{5.4\,\text{MeV}}$$

$$K_{\pi^-} = E_{\pi^-} - m_{\pi^-}c^2 = 172.0\,\text{MeV} - 139.6\,\text{MeV} = \boxed{32.4\,\text{MeV}}$$

25. (*a*) We work in the rest frame of the isolated electron, so that it is initially at rest. Energy conservation gives the following.

$$m_{\text{e}}c^2 = K_{\text{e}} + m_{\text{e}}c^2 + E_\gamma \quad \rightarrow \quad K_{\text{e}} = -E_\gamma \quad \rightarrow \quad K_{\text{e}} = E_\gamma = 0$$

Since the photon has no energy, it does not exist, and so has not been emitted.

(*b*) For the photon exchange in Figure 43-8, the photon exists for such a short time that the uncertainty principle allows energy to not be conserved during the exchange.

26. The total momentum of the electron and positron is 0, and so the total momentum of the two photons must be 0. Thus each photon has the same momentum, and so each photon also has the same energy. The total energy of the photons must be the total energy of the electron / positron pair.

$$E_{\text{e}^+/\text{e}^-\,\text{pair}} = E_{\text{photons}} \quad \rightarrow \quad 2\left(m_0c^2 + \text{KE}\right) = 2hf = 2h\frac{c}{\lambda} \quad \rightarrow$$

$$\lambda = \frac{hc}{m_0c^2 + \text{KE}} = \frac{\left(6.63\times10^{-34}\,\text{J}\cdot\text{s}\right)\left(3.00\times10^{8}\,\text{m/s}\right)}{\left(0.511\times10^{6}\,\text{eV} + 420\times10^{3}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 1.335\times10^{-12}\,\text{m} \approx \boxed{1.3\times10^{-12}\,\text{m}}$$

27. Since the pion decays from rest, the momentum before the decay is zero. Thus the momentum after the decay is also zero, and so the magnitudes of the momenta of the positron and the neutrino are equal. We also treat the neutrino as massless. Use energy and momentum conservation along with the relativistic relationship between energy and momentum.

$$m_{\pi^+}c^2 = E_{\text{e}^+} + E_\nu \quad ; \quad p_{\text{e}^+} = p_\nu \quad \rightarrow \quad \left(p_{\text{e}^+}^2c^2\right) = \left(p_\nu^2c^2\right) \quad \rightarrow \quad E_{\text{e}^+}^2 - m_{\text{e}^+}^2c^4 = E_\nu^2$$

$$E_{\text{e}^+}^2 - m_{\text{e}^+}^2c^4 = \left(m_{\pi^+}c^2 - E_{\text{e}^+}\right)^2 = m_{\pi^+}^2c^4 - 2E_{\text{e}^+}m_{\pi^+}c^2 + E_{\text{e}^+}^2 \quad \rightarrow \quad 2E_{\text{e}^+}m_{\pi^+}c^2 = m_{\pi^+}^2c^4 + m_{\text{e}^+}^2c^4$$

$$E_{\text{e}^+} = \tfrac{1}{2}m_{\pi^+}c^2 + \frac{m_{\text{e}^+}^2c^2}{2m_{\pi^+}} \quad \rightarrow \quad K_{\text{e}^+} + m_{\text{e}^+}c^2 = \tfrac{1}{2}m_{\pi^+}c^2 + \frac{m_{\text{e}^+}^2c^2}{2m_{\pi^+}} \quad \rightarrow$$

$$K_{\text{e}^+} = \tfrac{1}{2}m_{\pi^+}c^2 - m_{\text{e}^+}c^2 + \frac{m_{\text{e}^+}^2c^2}{2m_{\pi^+}} = \tfrac{1}{2}\left(139.6\,\text{MeV}\right) - 0.511\,\text{MeV} + \frac{\left(0.511\,\text{MeV}/c^2\right)\left(0.511\,\text{MeV}\right)}{2\left(139.6\,\text{MeV}/c^2\right)}$$

$$= \boxed{69.3\,\text{MeV}}$$

28. (*a*) For the reaction $\pi^- + \text{p} \rightarrow \text{n} + \eta^0$, the conservation laws are as follows.

Charge: $-1+1=0+0$	Charge is conserved.
Baryon number: $0+1=1+0$	Baryon number is conserved.
Lepton number: $0+0=0+0$	Lepton number is conserved.
Strangeness: $0+0=0+0$	Strangeness is conserved.

The reaction is possible.

(*b*) For the reaction $\pi^+ + \text{p} \rightarrow \text{n} + \pi^0$, the conservation laws are as follows.

Charge: $1+1\neq0+0$	Charge is NOT conserved.

The reaction is forbidden, because charge is not conserved.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) For the reaction $\pi^+ + \text{p} \rightarrow \text{p} + \text{e}^+$, the conservation laws are as follows.

Charge: $1+1=1+1$ Charge is conserved.
Baryon number: $0+1=1+0$ Baryon number is conserved.
Lepton number: $0+0\neq 0+1$ Lepton number is NOT conserved.

The reaction is forbidden, because lepton number is not conserved.

(*d*) For the reaction $\text{p} \rightarrow \text{e}^+ + \nu_\text{e}$, the conservation laws are as follows.

Charge: $1=1+0$ Charge is conserved.
Baryon number: $1\neq 0+0$ Baryon number NOT conserved.
Mass energy is fine, because $m_\text{p} > m_\text{e} + m_\nu$.

The reaction is forbidden, because baryon number is not conserved.

(*e*) For the reaction $\mu^+ \rightarrow \text{e}^+ + \overline{\nu}_\mu$, the conservation laws are as follows.

Charge: $1=1+0$ Charge is conserved.
Baryon number: $0=0+0$ Baryon number is conserved.
Electron lepton number: $0\neq -1+0$ Lepton number is NOT conserved.
Mass energy is fine, because $m_\mu > m_\text{e} + m_\nu$.

The reaction is forbidden, because lepton number is not conserved.

(*f*) For the reaction $\text{p} \rightarrow \text{n} + \text{e}^+ + \nu_\text{e}$, the conservation laws are as follows.

Mass energy: $938.3\,\text{MeV}/c^2 < 939.6\,\text{MeV}/c^2 + 0.511\,\text{MeV}/c^2$
Mass energy is NOT conserved.

The reaction is forbidden, because energy is not conserved.

29. Since the Ξ^- decays from rest, the momentum before the decay is zero. Thus the momentum after the decay is also zero, and so the momenta of the Λ^0 and π^- are equal in magnitude. Use energy and momentum conservation along with the relativistic relationship between energy and momentum.

$$m_{\Xi^-}c^2 = E_{\Lambda^0} + E_{\pi^-} \rightarrow E_{\pi^-} = m_{\Xi^-}c^2 - E_{\Lambda^0}$$

$$p_{\Lambda^0} = p_{\pi^-} \rightarrow \left(p_{\Lambda^0}c\right)^2 = \left(p_{\pi^-}c\right)^2 \rightarrow$$

$$E_{\Lambda^0}^2 - m_{\Lambda^0}^2c^4 = E_{\pi^-}^2 - m_{\pi^-}^2c^4 = \left(m_{\Xi^-}c^2 - E_{\Lambda^0}\right)^2 - m_{\pi^-}^2c^4$$

$$E_{\Lambda^0}^2 - m_{\Lambda^0}^2c^4 = \left(m_{\Xi^-}^2c^4 - 2E_{\Lambda^0}m_{\Xi^-}c^2 + E_{\Lambda^0}^2\right) - m_{\pi^-}^2c^4 \rightarrow$$

$$E_{\Lambda^0} = \frac{m_{\Xi^-}^2c^4 + m_{\Lambda^0}^2c^4 - m_{\pi^-}^2c^4}{2m_{\Xi^-}c^2} = \frac{\left(1321.3\,\text{MeV}\right)^2 + \left(1115.7\,\text{MeV}\right)^2 - \left(139.6\,\text{MeV}\right)^2}{2\left(1321.3\,\text{MeV}\right)} = 1124.3\,\text{MeV}$$

$$E_{\pi^-} = m_{\Xi^-}c^2 - E_{\Lambda^0} = 1321.3\,\text{MeV} - 1124.3\,\text{MeV} = 197.0\,\text{MeV}$$

$$K_{\Lambda^0} = E_{\Lambda^0} - m_{\Lambda^0}c^2 = 1124.3\,\text{MeV} - 1115.7\,\text{MeV} = \boxed{8.6\,\text{MeV}}$$

$$K_{\pi^-} = E_{\pi^-} - m_{\pi^-}c^2 = 197.0\,\text{MeV} - 139.6\,\text{MeV} = \boxed{57.4\,\text{MeV}}$$

30. $\text{p} + \text{p} \rightarrow \text{p} + \overline{\text{p}}$: This reaction will not happen because charge is not conserved $(2 \neq 0)$, and baryon number is not conserved $(2 \neq 0)$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$p + p \rightarrow p + p + \bar{p}$: This reaction will not happen because charge is not conserved $(2 \neq 1)$, and baryon number is not conserved $(2 \neq 1)$.

$p + p \rightarrow p + p + p + \bar{p}$: This reaction is possible. All conservation laws are satisfied.

$p + p \rightarrow p + e^+ + e^+ + \bar{p}$: This reaction will not happen. Baryon number is not conserved $(2 \neq 0)$, and lepton number is not conserved $(0 \neq -2)$.

31. The two neutrinos must move together, in the opposite direction of the electron, in order for the electron to have the maximum kinetic energy, and thus the total momentum of the neutrinos will be equal in magnitude to the momentum of the electron. Since a neutrino is (essentially) massless, we have $E_\nu = p_\nu c$. We assume that the muon is at rest when it decays. Use conservation of energy and momentum, along with their relativistic relationship.

$$p_{e^-} = p_{\bar{\nu}_e} + p_{\nu_\mu}$$

$$m_{\mu^-}c^2 = E_{e^-} + E_{\bar{\nu}_e} + E_{\nu_\mu} = E_{e^-} + p_{\bar{\nu}_e}c + p_{\nu_\mu}c = E_{e^-} + \left(p_{\bar{\nu}_e} + p_{\nu_\mu}\right)c = E_{e^-} + p_{e^-}c \rightarrow$$

$$m_{\mu^-}c^2 - E_{e^-} = p_{e^-}c \rightarrow \left(m_{\mu^-}c^2 - E_{e^-}\right)^2 = \left(p_{e^-}c\right)^2 = E_{e^-}^2 - m_{e^-}^2c^4 \rightarrow$$

$$m_{\mu^-}^2c^4 - 2m_{\mu^-}c^2E_{e^-} + E_{e^-}^2 = E_{e^-}^2 - m_{e^-}^2c^4 \rightarrow E_{e^-} = \frac{m_{\mu^-}^2c^4 + m_{e^-}^2c^4}{2m_{\mu^-}c^2} = K_{e^-} + m_{e^-}c^2 \rightarrow$$

$$K_{e^-} = \frac{m_{\mu^-}^2c^4 + m_{e^-}^2c^4}{2m_{\mu^-}c^2} - m_{e^-}c^2 = \frac{(105.7\,\text{MeV})^2 + (0.511\,\text{MeV})^2}{2(105.7\,\text{MeV})} - (0.511\,\text{MeV}) = \boxed{52.3\,\text{MeV}}$$

32. A π^+ could NOT be produced by $p + p \rightarrow p + n + \pi^+$. The pion has a mass energy of 139.6 MeV, and so the extra 100 MeV of energy could not create it. The *Q*-value for the reaction is $Q = 2m_pc^2 - \left(2m_pc^2 + m_{\pi^+}c^2\right) = -139.6\,\text{MeV}$, and so more than 139.6 MeV of kinetic energy is needed. The minimum initial kinetic energy would produce the particles all moving together at the same speed, having the same total momentum as the incoming proton. We consider the products to be one mass $M = m_p + m_n + m_{\pi^+}$ since they all move together with the velocity. We use energy and momentum conservation, along with their relativistic relationship, $E^2 = p^2c^2 + m_0^2c^4$.

$$E_p + m_pc^2 = E_M \quad ; \quad p_p = p_M \rightarrow \left(p_pc\right)^2 = \left(p_Mc\right)^2 \rightarrow E_p^2 - m_{\pi^-}^2c^4 = E_M^2 - M^2c^4 \rightarrow$$

$$E_p^2 - m_p^2c^4 = \left(E_p + m_pc^2\right)^2 - M^2c^4 = E_p^2 + 2E_pm_pc^2 + m_p^2c^4 - M^2c^4 \rightarrow$$

$$E_p = \frac{M^2c^4 - 2m_p^2c^4}{2m_pc^2} = K_p + m_pc^2 \rightarrow$$

$$K_p = \frac{M^2c^4 - 2m_p^2c^4}{2m_pc^2} - m_pc^2 = \frac{M^2c^4}{2m_pc^2} - 2m_pc^2$$

$$= \frac{(938.3\,\text{MeV} + 939.6\,\text{MeV} + 139.6\,\text{MeV})^2}{2(938.3\,\text{MeV})} - 2(938.3\,\text{MeV}) = \boxed{292.4\,\text{MeV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

33. We use the uncertainty principle to estimate the uncertainty in rest energy.

$$\Delta E \approx \frac{h}{2\pi\Delta t} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)}{2\pi\left(7\times10^{-20}\,\text{s}\right)\left(1.60\times10^{-16}\,\text{J/eV}\right)} = 9420\,\text{eV} \approx \boxed{9\,\text{keV}}$$

34. We estimate the lifetime from the energy width and the uncertainty principle.

$$\Delta E \approx \frac{h}{2\pi\Delta t} \;\rightarrow\; \Delta t \approx \frac{h}{2\pi\Delta E} = \frac{6.63\times10^{-34}\,\text{J•s}}{2\pi\left(300\times10^{3}\,\text{eV}\right)\left(\dfrac{1.60\times10^{-19}\,\text{J}}{1\,\text{eV}}\right)} = \boxed{2\times10^{-21}\,\text{s}}$$

Apply the uncertainty principle, which says that $\Delta E \approx \dfrac{h}{2\pi\Delta t}$.

$$\Delta E \approx \frac{h}{2\pi\Delta t} \;\rightarrow\; \Delta t \approx \frac{h}{2\pi\Delta E} = \frac{6.63\times10^{-34}\,\text{J•s}}{2\pi\left(88\times10^{3}\,\text{eV}\right)\left(\dfrac{1.60\times10^{-19}\,\text{J}}{1\,\text{eV}}\right)} = \boxed{7.5\times10^{-21}\,\text{s}}$$

36. (*a*) For $\text{B}^- = \text{b}\,\overline{\text{u}}$, we have

Charge:	$-1 = -\frac{1}{3} - \frac{2}{3}$	Spin:	$0 = \frac{1}{2} - \frac{1}{2}$
Baryon number:	$0 = \frac{1}{3} - \frac{1}{3}$	Strangeness:	$0 = 0 + 0$
Charm:	$0 = 0 + 0$	Bottomness:	$-1 = -1 + 0$
Topness:	$0 = 0 + 0$		

(*b*) Because B^+ is the antiparticle of B^-, $\boxed{\text{B}^+ = \overline{\text{b}}\,\text{u}}$. The B^0 still must have a bottom quark, but must be neutral. Therefore $\boxed{\text{B}^0 = \text{b}\,\overline{\text{d}}}$. Because $\overline{\text{B}}^0$ is the antiparticle to B^0, we must have $\boxed{\overline{\text{B}}^0 = \overline{\text{b}}\,\text{d}}$.

37. We find the energy width from the lifetime in Table 42-2 and the uncertainty principle.

(*a*) $\Delta t = 10^{-18}\,\text{s}$ $\quad \Delta E \approx \dfrac{h}{2\pi\Delta t} = \dfrac{6.63\times10^{-34}\,\text{J•s}}{2\pi\left(10^{-18}\,\text{s}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 659\,\text{eV} \approx \boxed{700\,\text{eV}}$

(*b*) $\Delta t = 10^{-23}\,\text{s}$ $\quad \Delta E \approx \dfrac{h}{2\pi\Delta t} = \dfrac{6.63\times10^{-34}\,\text{J•s}}{2\pi\left(10^{-23}\,\text{s}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 6.59\times10^{7}\,\text{eV} \approx \boxed{70\,\text{MeV}}$

38. (*a*)

Charge:	$(0) = (+1) + (-1)$	Charge is conserved.
Baryon number:	$(+1) = (+1) + (0)$	Baryon number is conserved.
Lepton number:	$(0) = (0) + (0)$	Lepton number is conserved.
Strangeness:	$(-2) \neq (-1) + (0)$	Strangeness is NOT conserved.
Energy:	$1314.9\,\text{Mev}/c^2 > 1189.4\,\text{Mev}/c^2 + 139.6\,\text{Mev}/c^2 = 1329\,\text{Mev}/c^2$	Energy is NOT conserved.

The decay is not possible, because energy is not conserved.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) Charge: $(-1)=(0)+(-1)+(0)$ Charge is conserved.

Baryon number: $(+1)=(+1)+(0)+(0)$ Baryon number is conserved.

Lepton number: $(0)=(0)+(0)+(1)$ Lepton number is NOT conserved.

Strangeness: $(-3)\neq(-1)+(0)+(0)$ Strangeness is NOT conserved.

Energy: $1672.5\,\text{Mev}/c^2 > 1192.6\,\text{Mev}/c^2 + 139.6\,\text{Mev}/c^2 + 0\,\text{Mev}/c^2 = 1332.2\,\text{Mev}/c^2$

Energy is conserved.

The decay is not possible, because lepton number is not conserved.

(*c*) Charge: $(0)=(0)+(0)+(0)$ Charge is conserved.

Baryon number: $(0)=(0)+(0)+(0)$ Baryon number is conserved.

Lepton number: $(0)=(0)+(0)+(0)$ Lepton number is conserved.

Strangeness: $(-1)=(-1)+(0)+(0)$ Strangeness is conserved.

Energy: $1192.6\,\text{Mev}/c^2 > 1115.7\,\text{Mev}/c^2 + 0\,\text{Mev}/c^2 + 0\,\text{Mev}/c^2 = 1115.7\,\text{Mev}/c^2$

Energy is conserved.

The decay is possible.

39. (*a*) The Ξ^0 has a strangeness of –2, and so must contain two strange quarks. In order to make a neutral particle, the third quark must be an up quark. So $\boxed{\Xi^0 = \text{u s s}}$.

(*b*) The Ξ^- has a strangeness of –2, and so must contain two strange quarks. In order to make a particle with a total charge of –1, the third quark must be a down quark. So $\boxed{\Xi^- = \text{d s s}}$.

40. (*a*) The neutron has a baryon number of 1, so there must be three quarks. The charge must be 0, as must be the strangeness, the charm, the bottomness, and the topness. Thus $\boxed{n = \text{u d d}}$.

(*b*) The antineutron is the anti particle of the neutron, and so $\boxed{\overline{n} = \overline{\text{u}}\,\overline{\text{d}}\,\overline{\text{d}}}$.

(*c*) The Λ^0 has a strangeness of -1, so it must contain an "s" quark. It is a baryon, so it must contain three quarks. And it must have charge, charm, bottomness, and topness equal to 0. Thus $\boxed{\Lambda^0 = \text{u d s}}$.

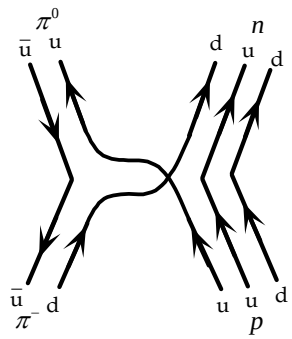
(*d*) The $\overline{\Sigma}^0$ has a strangeness of +1, so it must contain an $\overline{\text{s}}$ quark. It is a baryon, so it must contain three quarks. And it must have charge, charm, bottomness, and topness equal to 0. Thus $\boxed{\overline{\Sigma}^0 = \overline{\text{u}}\,\overline{\text{d}}\,\overline{\text{s}}}$.

41. (*a*) The combination u u d has charge = +1, baryon number = +1, and strangeness, charm, bottomness, and topness all equal to 0. Thus $\boxed{\text{u u d} = \text{p}}$.

(*b*) The combination $\overline{\text{u}}\,\overline{\text{u}}\,\overline{\text{s}}$ has charge = -1, baryon number = -1, strangeness = +1, and charm, bottomness, and topness all equal to 0. Thus $\boxed{\overline{\text{u}}\,\overline{\text{u}}\,\overline{\text{s}} = \overline{\Sigma}^-}$.

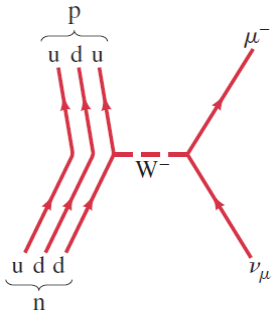
(*c*) The combination $\overline{\text{u}}\,\text{s}$ has charge = -1, baryon number = 0, strangeness = -1, and charm, bottomness, and topness all equal to 0. Thus $\boxed{\overline{\text{u}}\,\text{s} = \text{K}^-}$.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.



(*d*) The combination $\mathrm{d}\,\bar{\mathrm{u}}$ has charge = -1, baryon number = 0, and strangeness, charm, bottomness, and topness all equal to 0. Thus $\boxed{\mathrm{d}\,\bar{\mathrm{u}} = \pi^-}$

(*e*) The combination $\bar{\mathrm{c}}\,\mathrm{s}$ has charge = -1, baryon number = 0, strangeness = -1, charm = -1, and bottomness and topness of 0. Thus $\boxed{\bar{\mathrm{c}}\,\mathrm{s} = \mathrm{D}_S^-}$



42. To form the D^0 meson, we must have a total charge of 0, a baryon number of 0, a strangeness of 0, and a charm of +1. We assume that there is no topness or bottomness. To get the charm, we must have a "c" quark, with a charge of $+\frac{2}{3}e$. To have a neutral meson, there must be another quark with a charge of $-\frac{2}{3}e$. To have a baryon number of 0, that second quark must be an antiquark. The only candidate with those properties is an anti-up quark. Thus $\boxed{D^0 = \mathrm{c}\,\bar{\mathrm{u}}}$.

43. To form the D_S^+ meson, we must have a total charge of +1, a baryon number of 0, a strangeness of +1, and a charm of +1. We assume that there is no topness or bottomness. To get the charm, we must have a "c" quark, with a charge of $+\frac{2}{3}e$. To have a total charge of +1, there must be another quark with a charge of $+\frac{1}{3}e$. To have a baryon number of 0, that second quark must be an antiquark. To have a strangeness of +1, the other quark must be an anti-strange. Thus $\boxed{D_S^+ = \mathrm{c}\,\bar{\mathrm{s}}}$.

44. Here is a Feynman diagram for the reaction $\pi^- + \mathrm{p} \rightarrow \pi^0 + \mathrm{n}$.

45. Since leptons are involved, the reaction $\mathrm{n} + \nu_\mu \rightarrow \mathrm{p} + \mu^-$ is a weak interaction. Since there is a charge change in the lepton, a W boson must be involved in the interaction. If we consider the neutron as having emitted the boson, then it is a W^-, which interacts with the neutrino. If we consider the neutrino as having emitted the boson, then it is a W^+, which interacts with the neutron.

46. To find the length in the lab, we need to know the speed of the particle which is moving relativistically. Start with Eq. 36-10a.

$$K = m_0c^2\left(\frac{1}{\sqrt{1-v^2/c^2}} - 1\right) \rightarrow v = c\sqrt{1-\frac{1}{\left(\frac{K}{m_0c^2}+1\right)^2}} = c\sqrt{1-\frac{1}{\left(\frac{950\,\mathrm{MeV}}{1777\,\mathrm{MeV}}+1\right)^2}} = 0.7585c$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\Delta t_{\text{lab}} = \frac{\Delta t_0}{\sqrt{1-v^2/c^2}} = \frac{2.91\times10^{-13}\,\text{s}}{\sqrt{1-(0.7585)^2}} = 4.465\times10^{-13}\,\text{s}$$

$$\Delta x_{\text{lab}} = v\Delta t_{\text{lab}} = (0.7585)\left(3.00\times10^8\ \text{m/s}\right)\left(4.465\times10^{-13}\,\text{s}\right) = \boxed{1.02\times10^{-4}\,\text{m}}$$

47. (*a*) At an energy of 1.0 TeV, the protons are moving at practically the speed of light. From uniform circular motion we find the time for the protons to complete one revolution of the ring. Then the total charge that passes any point in the ring during that time is the charge of the entire group of stored protons. The current is then the total charge divided by the period.

$$v = \frac{2\pi R}{T} \quad \rightarrow \quad T = \frac{2\pi R}{v} = \frac{2\pi R}{c}$$

$$I = \frac{Ne}{T} = \frac{Nec}{2\pi R} = \frac{\left(5.0\times10^{13}\,\text{protons}\right)\left(1.60\times10^{-19}\,\text{C/proton}\right)\left(3.0\times10^8\ \text{m/s}\right)}{2\pi\left(1.0\times10^3\,\text{m}\right)} = \boxed{0.38\,\text{A}}$$

(*b*) The 1.0 TeV is equal to the kinetic energy of the proton beam.

$$K_{\text{beam}} = K_{\text{car}} \quad \rightarrow \quad K_{\text{beam}} = \tfrac{1}{2}mv^2 \quad \rightarrow$$

$$v = \sqrt{\frac{2K_{\text{beam}}}{m}} = \sqrt{\frac{2\left(1.0\times10^{12}\,\text{eV/proton}\right)\left(5.0\times10^{13}\,\text{protons}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}{1500\,\text{kg}}} = 103\,\text{m/s}$$

$$\approx \boxed{1.0\times10^2\ \text{m/s}}$$

48. By assuming that the kinetic energy is approximately 0, the total energy released is the rest mass energy of the annihilating pair of particles.

(*a*) $E_{\text{total}} = 2m_0c^2 = 2\left(0.511\,\text{MeV}\right) = \boxed{1.022\,\text{MeV}}$

(*b*) $E_{\text{total}} = 2m_0c^2 = 2\left(938.3\,\text{MeV}\right) = \boxed{1876.6\,\text{MeV}}$

49. These protons will be moving at essentially the speed of light for the entire time of acceleration. The number of revolutions is the total gain in energy divided by the energy gain per revolution. Then the distance is the number of revolutions times the circumference of the ring, and the time is the distance of travel divided by the speed of the protons.

$$N = \frac{\Delta E}{\Delta E/\text{rev}} = \frac{\left(1.0\times10^{12}\,\text{eV} - 150\times10^9\,\text{eV}\right)}{2.5\times10^6\ \text{eV/rev}} = 3.4\times10^5\,\text{rev}$$

$$d = N\left(2\pi R\right) = \left(3.4\times10^5\right)2\pi\left(1.0\times10^3\,\text{m}\right) = 2.136\times10^9\,\text{m} \approx \boxed{2.1\times10^9\,\text{m}}$$

$$t = \frac{d}{c} = \frac{2.136\times10^9\,\text{m}}{3.00\times10^8\ \text{m/s}} = \boxed{7.1\,\text{s}}$$

50. (*a*) For the reaction $\pi^- + \text{p} \rightarrow \text{K}^0 + \text{p} + \pi^0$, the conservation laws are as follows.

Charge: $-1+1 \neq 0+1+0$ Charge is NOT conserved.

The reaction is not possible, because charge is not conserved.

Also we note that the reactants would have to have significant kinetic energy to be able to "create" the K^0.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) For the reaction $K^- + p \rightarrow \Lambda^0 + \pi^0$, the conservation laws are as follows.

Charge: $-1+1=0+0$	Charge is conserved.
Spin: $0+\frac{1}{2}=\frac{1}{2}+0$	Spin is conserved.
Baryon number: $0+1=1+0$	Baryon number is conserved.
Lepton number: $0+0=0+0$	Lepton number is conserved.
Strangeness: $-1+0=-1+0$	Strangeness is conserved.

The reaction is possible, via the strong interaction.

(*c*) For the reaction $K^+ + n \rightarrow \Sigma^+ + \pi^0 + \gamma$, the conservation laws are as follows.

Charge: $1+0=1+0+0$	Charge is conserved.
Spin: $0+\frac{1}{2}=-\frac{1}{2}+0+1$	Spin is conserved.
Baryon number: $0+1=1+0+0$	Baryon number is conserved.
Lepton number: $0+0=0+0+0$	Lepton number is conserved.
Strangeness: $1+0\neq-1+0+0$	Strangeness is NOT conserved.

The reaction is not possible via the strong interaction because strangeness is not conserved. It is possible via the weak interaction.

(*d*) For the reaction $K^+ \rightarrow \pi^0 + \pi^0 + \pi^+$, the conservation laws are as follows.

Charge: $1=0+0+1$	Charge is conserved.
Spin: $0=0+0+0$	Spin is conserved.
Baryon number: $0=0+0+0$	Baryon number is conserved.
Lepton number: $0=0+0+0$	Lepton number is conserved.
Strangeness: $1\neq0+0+0$	Strangeness is NOT conserved.

The reaction is not possible via the strong interaction because strangeness is not conserved. It is possible via the weak interaction.

(*e*) For the reaction $\pi^+ \rightarrow e^+ + \nu_e$, the conservation laws are as follows.

Charge: $1=1+0$	Charge is conserved.
Spin: $0=-\frac{1}{2}+\frac{1}{2}$	Spin is conserved.
Baryon number: $0=0+0$	Baryon number is conserved.
Lepton number: $0=-1+1$	Lepton number is conserved.
Strangeness: $0+0=0+0+0$	Strangeness is conserved.

The reaction is possible, via the weak interaction.

51. (*a*) For the reaction $\pi^- + p \rightarrow K^+ + \Sigma^-$, the conservation laws are as follows.

Charge: $-1+1=1-1$	Charge is conserved.
Baryon number: $0+1=0+1$	Baryon number is conserved.
Lepton number: $0+0=0+0$	Lepton number is conserved.
Strangeness: $0+0=1-1$	Strangeness is conserved.

The reaction is possible, via the strong interaction.

(*b*) For the reaction $\pi^+ + p \rightarrow K^+ + \Sigma^+$, the conservation laws are as follows.

Charge: $1+1=1+1$	Charge is conserved.
Baryon number: $0+1=0+1$	Baryon number is conserved.
Lepton number: $0+0=0+0$	Lepton number is conserved.
Strangeness: $0+0=1-1$	Strangeness is conserved.

The reaction is possible, via the strong interaction.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*c*) For the reaction $\pi^- + \text{p} \rightarrow \Lambda^0 + \text{K}^0 + \pi^0$, the conservation laws are as follows.

Charge: $-1+1=0+0+0$	Charge is conserved.
Baryon number: $0+1=1+0+0$	Baryon number is conserved.
Lepton number: $0+0=0+0+0$	Lepton number is conserved.
Strangeness: $0+0=-1+1+0$	Strangeness is conserved.

The reaction is possible, via the strong interaction.

(*d*) For the reaction $\pi^+ + \text{p} \rightarrow \Sigma^0 + \pi^0$, the conservation laws are as follows.

Charge: $1+1\neq 0+0$	Charge is NOT conserved.

The reaction is not possible, because charge is not conserved.

(*e*) For the reaction $\pi^- + \text{p} \rightarrow \text{p} + \text{e}^- + \overline{\nu}_\text{e}$, the conservation laws are as follows.

Charge: $-1+1=1-1+0$	Charge is conserved.
Baryon number: $0+1=1+0+0$	Baryon number is conserved.
Lepton number: $0+0=0+1-1$	Lepton number is conserved.
Strangeness: $0+0=0+0+0$	Strangeness is conserved.

The reaction is possible, via the weak interaction.

Note that we did not check mass conservation, because in a collision, there is always some kinetic energy brought into the reaction. Thus the products can be heavier than the reactants.

52. The π^- is the anti-particle of the π^+, so the reaction is $\boxed{\pi^- \rightarrow \mu^- + \overline{\nu}_\mu}$. The conservation rules are as follows.

Charge: $-1=-1+0$	Charge is conserved.
Baryon number: $0=0+0$	Baryon number is conserved.
Lepton number: $0=1-1$	Lepton number is conserved.
Strangeness: $0=0+0$	Strangeness is conserved.
Spin: $0=\frac{1}{2}-\frac{1}{2}$	Spin is conserved

53. Use Eq. 43-3 to estimate the mass of the particle based on the given distance.

$$mc^2 \approx \frac{hc}{2\pi d} = \frac{\left(6.63\times10^{-34}\,\text{J•s}\right)\left(3.0\times10^{8}\,\text{m/s}\right)}{2\pi\left(10^{-18}\,\text{m}\right)}\left(\frac{1}{1.60\times10^{-19}\,\text{J/eV}}\right) = 1.98\times10^{11}\,\text{eV} \approx \boxed{200\,\text{GeV}}$$

This value is of the same order of magnitude as the mass of the $\text{W}^\pm$.

54. The *Q*-value is the mass energy of the reactants minus the mass energy of the products.

For the first reaction, $\text{p} + \text{p} \rightarrow \text{p} + \text{p} + \pi^0$:

$$Q = 2m_\text{p}c^2 - \left(2m_\text{p}c^2 + m_{\pi^0}c^2\right) = -m_{\pi^0}c^2 = \boxed{-135.0\,\text{MeV}}$$

For the second reaction, $\text{p} + \text{p} \rightarrow \text{p} + \text{n} + \pi^+$:

$$Q = 2m_\text{p}c^2 - \left(m_\text{p}c^2 + m_\text{n}c^2 + m_{\pi^+}c^2\right) = m_\text{p}c^2 - m_\text{n}c^2 - m_{\pi^+}c^2 a$$

$$= 938.3\,\text{MeV} - 939.6\,\text{MeV} - 139.6\,\text{MeV} = \boxed{-140.9\,\text{MeV}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

55. The fundamental fermions are the quarks and electrons. In a water molecule there are 2 hydrogen atoms consisting of one electron and one proton each, and 1 oxygen atom, consisting of 8 electrons, 8 protons, and 8 neutrons. Thus there are 18 nucleons, consisting of 3 quarks each, and 10 electrons. The total number of fermions is thus $18\times 3+10=\boxed{64 \text{ fermions}}$.

56. We assume that the interaction happens essentially at rest, so that there is no initial kinetic energy or momentum. Thus the momentum of the neutron and the momentum of the π^0 will have the same magnitude. From energy conservation we find the total energy of the π^0.

$$m_{\pi^-}c^2 + m_{\text{p}}c^2 = E_{\pi^0} + m_{\text{n}}c^2 + K_{\text{n}} \rightarrow$$

$$E_{\pi^0} = m_{\pi^-}c^2 + m_{\text{p}}c^2 - \left(m_{\text{n}}c^2 + K_{\text{n}}\right) = 139.6\,\text{MeV} + 938.3\,\text{MeV} - \left(939.6\,\text{MeV} + 0.60\,\text{MeV}\right)$$
$$= 137.7\,\text{MeV}$$

From momentum conservation, we can find the mass energy of the π^0. We utilize Eq. 36-13 to relate momentum and energy.

$$p_{\text{n}} = p_{\pi^0} \rightarrow \left(p_{\text{n}}c\right)^2 = \left(p_{\pi^0}c\right)^2 \rightarrow E_{\text{n}}^2 - m_{\text{n}}^2c^4 = E_{\pi^0}^2 - m_{\pi^0}^2c^4 \rightarrow m_{\pi^0}^2c^4 = E_{\pi^0}^2 - E_{\text{n}}^2 + m_{\text{n}}^2c^4 \rightarrow$$

$$m_{\pi^0}c^2 = \sqrt{E_{\pi^0}^2 - E_{\text{n}}^2 + m_{\text{n}}^2c^4} = \left[\left(137.7\,\text{MeV}\right)^2 - \left(939.6\,\text{MeV} + 0.60\,\text{MeV}\right)^2 + \left(939.6\,\text{MeV}\right)^2\right]^{1/2}$$

$$= 133.5\,\text{MeV} \rightarrow m_{\pi^0} = \boxed{133.5\,\text{MeV}/c^2}$$

The value from Table 43-2 is 135.0 MeV.

57. (*a*) First we use the uncertainty principle, Eq. 38-1. The energy is so high that we assume $E = pc$, and so $\Delta p = \dfrac{\Delta E}{c}$.

$$\Delta x \Delta p \approx \frac{h}{2\pi} \rightarrow \Delta x \frac{\Delta E}{c} \approx \frac{h}{2\pi} \rightarrow$$

$$\Delta E \approx \frac{hc}{2\pi\Delta x} = \frac{\left(6.63\times 10^{-34}\,\text{J}\cdot\text{s}\right)\left(3.00\times 10^{8}\,\text{m/s}\right)}{2\pi\left(10^{-32}\,\text{m}\right)} \frac{\left(1\,\text{GeV}/10^{9}\,\text{eV}\right)}{\left(1.60\times 10^{-19}\,\text{J/eV}\right)} = \boxed{2\times 10^{16}\,\text{GeV}}$$

Next, we use de Broglie's wavelength formula. We take the de Broglie wavelength as the unification distance.

$$\lambda = \frac{h}{p} = \frac{h}{Ec} \rightarrow$$

$$E = \frac{hc}{\lambda} = \frac{\left(6.63\times 10^{-34}\,\text{J}\cdot\text{s}\right)\left(3.00\times 10^{8}\,\text{m/s}\right)}{\left(10^{-32}\,\text{m}\right)} \frac{\left(1\,\text{GeV}/10^{9}\,\text{eV}\right)}{\left(1.60\times 10^{-19}\,\text{J/eV}\right)} = \boxed{1\times 10^{17}\,\text{GeV}}$$

Both energies are reasonably close to $10^{16}\,\text{GeV}$. This energy is the amount that could be violated in conservation of energy if the universe were the size of the unification distance.

(*b*) From Eq. 18-4, we have $E = \frac{3}{2}kT$.

$$E = \tfrac{3}{2}kT \rightarrow T = \frac{2E}{3k} = \frac{2\left(10^{25}\,\text{eV}\right)\left(1.6\times 10^{-19}\,\text{J/eV}\right)}{3\left(1.38\times 10^{-23}\,\text{J/K}\right)} = 7.7\times 10^{28}\,\text{K} \approx \boxed{10^{29}\,\text{K}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

58. The *Q*-value is the mass energy of the reactants minus the mass energy of the products.

$$Q = m_{\pi^-}c^2 + m_{\mathrm{p}}c^2 - \left(m_{\Lambda^0}c^2 + m_{\mathrm{K}^0}c^2\right) = 139.6\,\mathrm{MeV} + 938.3\,\mathrm{MeV} - \left(1115.7\,\mathrm{MeV} + 497.7\,\mathrm{MeV}\right)$$

$$= \boxed{-535.5\,\mathrm{MeV}}$$

We consider the products to be one mass $M = m_{\Lambda^0} + m_{\mathrm{K}^0} = 1613.4\,\mathrm{MeV}/c^2$ since they both have the same velocity. Energy conservation gives the following: $E_{\pi^-} + m_{\mathrm{p}}c^2 = E_M$. Momentum conservation says that the incoming momentum is equal to the outgoing momentum. Then convert that relationship to energy using the relativistic relationship that $E^2 = p^2c^2 + m^2c^4$.

$$p_{\pi^-} = p_{\mathrm{M}} \;\rightarrow\; \left(p_{\pi^-}c\right)^2 = \left(p_{\mathrm{M}}c\right)^2 \;\rightarrow\; E_{\pi^-}^2 - m_{\pi^-}^2c^4 = E_M^2 - M^2c^4 \;\rightarrow$$

$$E_{\pi^-}^2 - m_{\pi^-}^2c^4 = \left(E_{\pi^-} + m_{\mathrm{p}}c^2\right)^2 - M^2c^4 = E_{\pi^-}^2 + 2E_{\pi^-}m_{\mathrm{p}}c^2 + m_{\mathrm{p}}^2c^4 - M^2c^4 \;\rightarrow$$

$$E_{\pi^-} = \frac{M^2c^4 - m_{\pi^-}^2c^4 - m_{\mathrm{p}}^2c^4}{2m_{\mathrm{p}}c^2} = K_{\pi^-} + m_{\pi^-}c^2 \;\rightarrow$$

$$K_{\pi^-} = \frac{M^2c^4 - m_{\pi^-}^2c^4 - m_{\mathrm{p}}^2c^4}{2m_{\mathrm{p}}c^2} - m_{\pi^-}c^2$$

$$= \frac{\left(1613.4\,\mathrm{MeV}\right)^2 - \left(139.6\,\mathrm{MeV}\right)^2 - \left(938.3\,\mathrm{MeV}\right)^2}{2\left(938.3\,\mathrm{MeV}\right)} - \left(139.6\,\mathrm{MeV}\right) = \boxed{768.0\,\mathrm{MeV}}$$

59. Since there is no initial momentum, the final momentum must add to zero. Thus each of the pions must have the same magnitude of momentum, and therefore the same kinetic energy. Use energy conservation to find the kinetic energy of each pion.

$$2m_{\mathrm{p}}c^2 = 2K_{\pi} + 2m_{\pi}c^2 \;\rightarrow\; K_{\pi} = m_{\mathrm{p}}c^2 - m_{\pi}c^2 = 938.3\,\mathrm{MeV} - 139.6\,\mathrm{MeV} = \boxed{798.7\,\mathrm{MeV}}$$

60. The *Q*-value is the energy of the reactants minus the energy of the products. We assume that one of the initial protons is at rest, and that all four final particles have the same velocity and therefore the same kinetic energy, since they all have the same mass. We consider the products to be one mass $M = 4m_{\mathrm{p}}$ since they all have the same velocity.

$$Q = 2m_{\mathrm{p}}c^2 - 4m_{\mathrm{p}}c^2 = 2m_{\mathrm{p}}c^2 - Mc^2 = -2m_{\mathrm{p}}c^2$$

Energy conservation gives the following, where K_{th} is the threshold energy.

$$\left(K_{\mathrm{th}} + m_{\mathrm{p}}c^2\right) + m_{\mathrm{p}}c^2 = E_M = K_M + Mc^2$$

Momentum conservation says that the incoming momentum is equal to the outgoing momentum. Then convert that relationship to energy using the relativistic relationship that $E^2 = p^2c^2 + m_0^2c^4$.

$$p_{\mathrm{p}} = p_{\mathrm{M}} \;\rightarrow\; \left(p_{\mathrm{p}}c\right)^2 = \left(p_{\mathrm{M}}c\right)^2 \;\rightarrow\; \left(K_{\mathrm{th}} + m_{\mathrm{p}}c^2\right)^2 - m_{\mathrm{p}}^2c^4 = \left(K_M + Mc^2\right)^2 - M^2c^4 \;\rightarrow$$

$$K_{\mathrm{th}}^2 + 2K_{\mathrm{th}}m_{\mathrm{p}}c^2 + m_{\mathrm{p}}^2c^4 - m_{\mathrm{p}}^2c^4 = K_{\mathrm{th}}^2 + 4K_{\mathrm{th}}m_{\mathrm{p}}c^2 + 4m_{\mathrm{p}}^2c^4 - \left(4m_{\mathrm{p}}\right)^2c^4 \;\rightarrow$$

$$2K_{\mathrm{th}}m_{\mathrm{p}}c^2 = 4K_{\mathrm{th}}m_{\mathrm{p}}c^2 + 4m_{\mathrm{p}}^2c^4 - 16m_{\mathrm{p}}^2c^4 \;\rightarrow\; 2K_{\mathrm{th}}m_{\mathrm{p}}c^2 = 12m_{\mathrm{p}}^2c^4 \;\rightarrow$$

$$K_{\mathrm{th}} = 6m_{\mathrm{p}}c^2 = 3\left|Q\right|$$

61. The total energy is the sum of the kinetic energy and the mass energy. The wavelength is found from the relativistic momentum.

$$E = K + mc^2 = 15\times10^9\,\text{eV} + 938\times10^6\,\text{eV} = 1.594\times10^{10}\,\text{eV} \approx \boxed{16\,\text{GeV}}$$

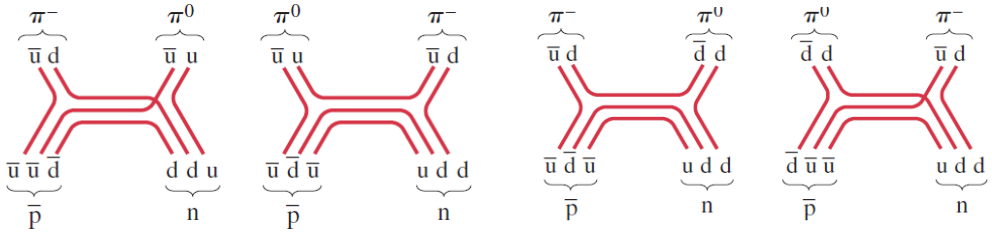
$$\lambda = \frac{h}{p} = \frac{h}{\dfrac{\sqrt{E^2 - \left(mc^2\right)^2}}{c}} = \frac{hc}{\sqrt{E^2 - \left(mc^2\right)^2}}$$

$$= \frac{\left(6.63\times10^{-34}\,\text{J}\cdot\text{s}\right)\left(3.00\times10^8\,\text{m/s}\right)}{\sqrt{\left(1.594\times10^{10}\,\text{eV}\right)^2 - \left(938\times10^6\,\text{eV}\right)^2}}\frac{1}{\left(1.60\times10^{-19}\,\text{J/eV}\right)} = \boxed{7.8\times10^{-17}\,\text{m}}$$

62. We use λ_0 to represent the actual wavelength, and λ to define the approximate wavelength. The approximation is to ignore the rest mass in the expression for the total energy, $E = K + mc^2$. We also use Eqs. 36-10, 36-11, 36-13, and 43-1.

$$p^2c^2 = E^2 - \left(mc^2\right)^2 = \left(K + mc^2\right)^2 - \left(mc^2\right)^2 = K^2\left(1 + 2\frac{mc^2}{K}\right)$$

$$\lambda_0 = \frac{h}{p} = \frac{hc}{K\left(1 + \dfrac{2mc^2}{K}\right)^{1/2}} \;;\; \lambda = \frac{hc}{K} > \lambda_0 \;;\; \lambda = 1.01\lambda_0 \;\rightarrow$$



$$\frac{hc}{K} = 1.01\frac{hc}{K\left(1 + \dfrac{2mc^2}{K}\right)^{1/2}} \;\rightarrow\; K = \frac{2mc^2}{\left(1.01\right)^2 - 1} = \frac{2\left(9.38\times10^8\,\text{eV}\right)}{0.0201} = 9.333\times10^{10}\,\text{eV} \approx \boxed{9.3\times10^{10}\,\text{eV}}$$

$$\lambda = \frac{hc}{K} = \frac{\left(6.63\times10^{-34}\,\text{J}\cdot\text{s}\right)\left(3.00\times10^8\,\text{m/s}\right)}{\left(9.333\times10^{10}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)} = 1.332\times10^{-17}\,\text{m} \approx \boxed{1.3\times10^{-17}\,\text{m}}$$

$$K = \left(\frac{1}{\sqrt{1 - v^2/c^2}} - 1\right)mc^2 \;\rightarrow$$

$$v = c\sqrt{1 - \left(\frac{K}{mc^2} + 1\right)^{-2}} = c\sqrt{1 - \left(\frac{9.333\times10^{10}\,\text{eV}}{9.38\times10^8\,\text{eV}} + 1\right)^{-2}} = \boxed{0.99995c}$$

63. As mentioned in Example 43-9, the π^0 can be considered as either $\text{u}\,\bar{\text{u}}$ or $\text{d}\,\bar{\text{d}}$. There are various models to describe this reaction. Four are shown here.

64. (*a*) To conserve charge, the missing particle must be neutral. To conserve baryon number, the missing particle must be a meson. To conserve strangeness, charm, topness, and bottomness, the missing particle must be made of up and down quarks and antiquarks only. With all this information, the missing particle is $\boxed{\pi^0}$.

(*b*) This is a weak interaction since one product is a lepton. To conserve charge, the missing particle must be neutral. To conserve the muon lepton number, the missing particle must be an antiparticle in the muon family. With this information, the missing particle is $\boxed{\overline{\nu}_\mu}$.

65. A relationship between total energy and speed is given by Eq. 36-11b.

$$E = \frac{mc^2}{\sqrt{1-v^2/c^2}} \quad \rightarrow$$

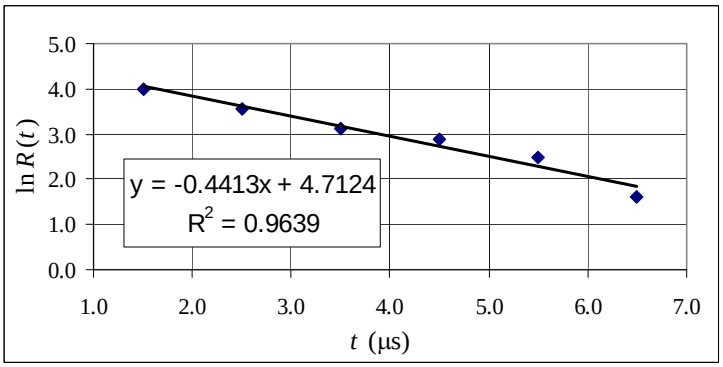
$$\frac{v}{c} = \sqrt{1-\left(\frac{mc^2}{E}\right)^2} = \sqrt{1-\left(\frac{9.38\times10^8\,\text{eV}}{7.0\times10^{12}\,\text{eV}}\right)^2} \approx 1-\tfrac{1}{2}\left(\frac{9.38\times10^8\,\text{eV}}{7.0\times10^{12}\,\text{eV}}\right)^2 = \boxed{1-9.0\times10^{9}}$$

66. We write equations for both conservation of energy and conservation of momentum. The magnitudes of the momenta of the products are equal. We also use Eqs. 36-11 and 36-13.

$$p_1 = p_2 \;;\; E_0 = mc^2 = E_1 + E_2 \quad \rightarrow$$

$$\left(mc^2 - E_1\right)^2 = E_2^2 = p_2^2c^2 + m_2^2c^4 = p_1^2c^2 + m_2^2c^4 = E_1^2 - m_1^2c^4 + m_2^2c^4 \quad \rightarrow$$

$$m^2c^4 - 2mc^2E_1 + E_1^2 = E_1^2 - m_1^2c^4 + m_2^2c^4 \quad \rightarrow \quad E_1 = \frac{m^2c^4 + m_1^2c^4 - m_2^2c^4}{2mc^2}$$



$$K_1 = E_1 - m_1c^2 = \frac{m^2c^4 + m_1^2c^4 - m_2^2c^4}{2mc^2} - m_1c^2 = \frac{m^2c^4 + m_1^2c^4 - m_2^2c^4 - 2mc^2m_1c^2}{2mc^2}$$

$$= \boxed{\frac{\left(mc^2 - m_1c^2\right)^2 - m_2^2c^4}{2mc^2}}$$

67. The value of R_0 is not known until we draw the graph. We note the following:

$$R = R_0e^{-t/\tau} \quad \rightarrow \quad R/R_0 = e^{-t/\tau} \quad \rightarrow \quad \ln R - \ln R_0 = -t/\tau \quad \rightarrow \quad \ln R = -t/\tau + \ln R_0$$

A graph of $\ln R$ vs. t should give a straight line with a slope of $-1/\tau$ and a y-intercept of $\ln R_0$. The determination of the mean life does not depend on R_0, and so to find the mean life, we may simply plot $\ln R$ vs. t. That graph is shown, along with the slope and y-intercept. The spreadsheet used for this problem can be found on the Media Manager, with filename "PSE4_ISM_CH43.XLS," on tab "Problem 43.67."

$$\tau = \frac{1}{0.4413} = 2.266\,\mu\text{s} \approx \boxed{2.3\,\mu\text{s}} \qquad \%\,\text{diff} = \frac{2.266 - 2.197}{2.197}\times100 = \boxed{3.1\%}$$

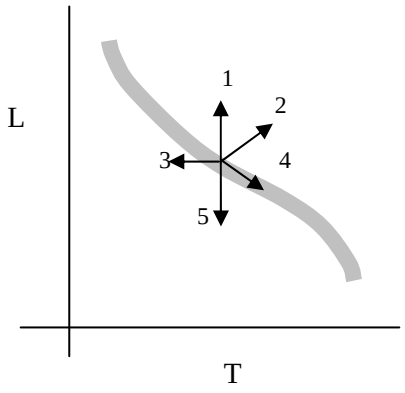
CHAPTER 44: Astrophysics and Cosmology



Responses to Questions

1. The Milky Way appears "murky" or "milky" to the naked eye, and so before telescopes were used it was thought to be cloud-like. When viewed with a telescope, much of the "murkiness" is resolved into stars and star clusters, so we no longer consider the Milky Way to be milky.

2. If a star generates more energy in its interior than it radiates away, its temperature will increase. Consequently, there will be greater outward pressure opposing the gravitational force directed inward. To regain equilibrium, the star will expand. If a star generates less energy than it radiates away, then its temperature will decrease. There will be a smaller outward pressure opposing the gravitational force directed inward, and, in order to regain equilibrium, the star will contract.

3. Red giants are extremely large stars with relatively cool surface temperatures, resulting in their reddish colors. These stars are very luminous because they are so large. When the Sun becomes a red giant, for instance, its radius will be on the order of the distance from the Earth to the Sun. A red giant has run out of hydrogen in its inner core and is fusing hydrogen to helium in a shell surrounding the core. Red giants have left their main sequence positions on the H–R diagram and moved up (more luminous) and to the right (cooler).

4. A star moving along arrow #1 would increase in luminosity while maintaining the same surface temperature. It would therefore also have to increase in size, since each square meter of its surface would have the same color and therefore same energy output as before. A star moving along arrow #2 would increase in luminosity and decrease in temperature. It would also increase in size, since it would need to produce a greater luminosity even though each unit area of its surface would now be producing less energy. A star moving along arrow #3 maintains the same luminosity while increasing its surface temperature. It will become smaller, since a unit area of this star will increase its energy and therefore a smaller overall area will be needed to maintain the same luminosity. A star moving along arrow #4 decreases in both surface temperature and luminosity. Finally, a star moving along arrow #5 will decrease in luminosity while maintaining the same surface temperature and decreasing in size. Note that these arrows do not necessarily represent "natural" paths for stars on the H–R diagram.

5. The H–R diagram is a plot of luminosity versus surface temperature of a star and therefore does not directly tell us anything about the core of a star. However, when considered in conjunction with theories of stellar evolution, the H–R diagram does relate to the interior of a star. For instance, all main sequence stars are fusing hydrogen to helium in their cores, so the location of a particular star on the main sequence does give us that information.

6. The fate of a star depends on the mass of the star remaining after the red giant phase. If the mass is less than about 1.4 solar masses, the star will become a white dwarf. If the mass is greater than this limit, than the exclusion principle applied to electrons is not enough to hold the star up against its own gravity and it continues to contract, eventually becoming a neutron star or, if its mass at this stage is more than two or three solar masses, a black hole.

7. Yes. Hotter stars are found on the main sequence above and to the left of cooler stars. If H–R diagrams of clusters of stars are compared, it is found that older clusters are missing the upper left portions of their main sequences. All the stars in a given cluster are formed at about the same time, and the absence of the hotter main sequence stars in a cluster indicates that they have shorter lives and have already used up their core hydrogen and become red giants. In fact, the "turn-off" point, or point at which the upper end of the main sequence stops, can be used to determine the ages of clusters.

8. The baseline used in measuring parallaxes from the Earth is the distance from the Earth to the Sun. (See Figure 44-11.) If you were measuring parallaxes from the Moon instead, you would need to make a slight correction based on the position of the Moon with respect to the Earth–Sun line at the time of the measurement. If you were measuring parallaxes from Mars, you would need to use the distance from Mars to the Sun as the baseline. In addition, you would need to wait half a Martian year between measurements instead of half an Earth year.

9. Watch the star over a period of several days and determine its period through observation. Use the known relationship between period and luminosity to find its absolute luminosity. Compare its absolute luminosity to its apparent luminosity (observed) to determine the distance to the galaxy in which it is located.

10. A geodesic is the shortest distance between two points. For instance, on a flat plane the shortest distance between two points is a straight line, and on the surface of a sphere the shortest distance is an arc of a great circle. According to general relativity, space–time is curved. Determining the nature of a geodesic, for instance by observing the motion of a body or light near a large mass, will help determine the nature of the curvature of space–time there.

11. If the redshift of spectral lines of galaxies were discovered to be due to something other than expansion of the universe, then the Big Bang theory and the idea that the universe is expanding would be called into question. However, the evidence of the cosmic background microwave radiation would conflict with this view, unless it too was determined to result from some cause other than expansion.

12. No. In an expanding universe, all galaxies are moving away from all other galaxies on a large scale. (On a small scale, neighboring galaxies may be gravitationally bound to each other.) Therefore, the view from any galaxy would be the same. Our observations do not indicate that we are at the center. (See Figure 44-23.)

13. They would appear to be receding. In an expanding universe, the distances between galaxies are increasing, and so the view from any galaxy is that all other galaxies are moving away.

14. An explosion on Earth would be affected by the Earth's gravity and air resistance. Each piece of debris would act like a projectile, with its individual initial velocity. More distant particles would not spread at a higher speed. This corresponds somewhat to a closed universe, in which the galaxies eventually stop and then all come back together again. In the case of the explosion on Earth, most of the particles would eventually stop. Most would land on the ground. Some might escape into space. The particles would not all reassemble, as in the "big crunch."

15. Black holes have tremendous gravity, so we can detect them by the gravitational deflection of other objects in their vicinity. Also, matter accelerating toward a black hole gives off x-rays, which can be detected. In addition, gravitational lensing, the bending of light coming from stars and galaxies located behind the black hole, can indicate that the black hole is present.

16. $R = 2GM/c^2$, so $M = Rc^2/2G$.

$M = (5.29 \times 10^{-11})(3.00 \times 10^8)^2/[2(6.67 \times 10^{-11})] = 3.57 \times 10^{16}$ kg

17. Both the formation of the Earth and the time during which people have lived on Earth are on the far right edge of Figure 44-30, in the era of dark energy.

18. The 2.7 K cosmic microwave background radiation is the remnant radiation of the Big Bang. As the universe expanded, the wavelengths of the Big Bang radiation lengthened and became redshifted. The 2.7 K blackbody curve peaks at a wavelength of about 7.35 cm, in the microwave region. The temperature of this radiation is low because the energy spread out over an increasingly large volume as the universe expanded.

19. The early universe was too hot for atoms to exist. The average kinetic energies of particles were high and frequent collisions prevented electrons from remaining with nuclei.

20. (*a*) Type Ia supernovae have a range of luminosities that can be extracted from their observable characteristics and can be derived from the rate at which they brighten and fade away.
(*b*) The distance to a supernova can be determined by comparing the relative intensity to the luminosity.

21. The initial Big Bang was not perfectly symmetric. Deviations in the symmetry enabled the development of galaxies and other structures.

22. If the average mass density of the universe is above the critical density, then the universe will eventually stop its expansion and contract, collapsing on itself and ending finally in a "big crunch." This scenario corresponds to a closed universe, or one with positive curvature.

23. If there were 7 protons for every neutron, and it takes two protons and two neutrons to create a single helium nucleus, then for every helium nucleus there would be 12 hydrogen nuclei. Since the mass of helium is four times the mass of hydrogen, the ratio of the total mass of hydrogen to the total mass of helium should be 12:4, or 3:1.

24. (*a*) Gravity between galaxies should be pulling the galaxies back together, slowing the expansion of the universe.
(*b*) Astronomers could measure the redshift of light from distant supernovae and deduce the recession velocities of the galaxies in which they lie. By obtaining data from a large number of supernovae, they could establish a history of the recessional velocity of the universe, and perhaps tell whether the expansion of the universe is slowing down.

Solutions to Problems

1. Convert the angle to seconds of arc, reciprocate to find the distance in parsecs, and then convert to light years.

$$\phi = \left(2.9 \times 10^{-4}\right)^{\circ}\left(\frac{3600''}{1^{\circ}}\right) = 1.044''$$

$$d\,(\text{pc}) = \frac{1}{\phi''} = \frac{1}{1.044''} = 0.958\,\text{pc}\left(\frac{3.26\,\text{ly}}{1\,\text{pc}}\right) = \boxed{3.1\,\text{ly}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

2. Use the angle to calculate the distance in parsecs, and then convert to light years.

$$d\,(\text{pc}) = \frac{1}{\phi''} = \frac{1}{0.27''} = 3.704\,\text{pc} \quad \rightarrow \quad 3.704\,\text{pc}\left(\frac{3.26\,\text{ly}}{1\,\text{pc}}\right) = \boxed{12\,\text{ly}}$$

3. Convert the light years to parsecs, and then take the reciprocal of the number of parsecs to find the parallax angle in seconds of arc.

$$65\,\text{ly}\left(\frac{1\,\text{pc}}{3.26\,\text{ly}}\right) = 19.94\,\text{pc} \approx \boxed{20\,\text{pc}} \;\; (2\text{ sig. fig.}) \qquad \phi = \frac{1}{19.94\,\text{pc}} = \boxed{0.050''}$$

4. The reciprocal of the distance in parsecs is the angle in seconds of arc.

(*a*) $\phi'' = \dfrac{1}{d\,(\text{pc})} = \dfrac{1}{56\,\text{pc}} = 0.01786 \approx \boxed{0.018''}$

(*b*) $0.01786''\left(\dfrac{1^\text{o}}{3600''}\right) = \left(4.961\times10^{-6}\right)^\text{o} \approx \boxed{\left(5.0\times10^{-6}\right)^\text{o}}$

5. The parallax angle is $\boxed{\text{smaller}}$ for the further star. Since $\tan\phi = d/D$, as the distance D to the star increases, the tangent decreases, so the angle decreases. And since for small angles, $\tan\phi \approx \phi$, we have that $\phi \approx d/D$. Thus if the distance D is doubled, the angle ϕ will be $\boxed{\text{smaller by a factor of 2}}$.

6. Find the distance in light years. That value is also the time for light to reach us.

$$85\,\text{pc}\left(\frac{3.26\,\text{ly}}{1\,\text{pc}}\right) = 277\,\text{ly} \approx 280\,\text{ly} \quad \rightarrow \quad \text{It takes light } \boxed{280\,\text{years}} \text{ to reach us.}$$

7. The apparent brightness of an object is inversely proportional to the square of the observer's distance from the object, given by Eq. 44-1. To find the relative brightness at one location as compared to another, take a ratio of the apparent brightness at each location.

$$\frac{b_\text{Jupiter}}{b_\text{Earth}} = \frac{\dfrac{L}{4\pi d_\text{Jupiter}^2}}{\dfrac{L}{4\pi d_\text{Earth}^2}} = \frac{d_\text{Earth}^2}{d_\text{Jupiter}^2} = \left(\frac{d_\text{Earth}}{d_\text{Jupiter}}\right)^2 = \left(\frac{1}{5.2}\right)^2 = \boxed{0.037}$$

8. (*a*) The apparent brightness is the solar constant, $\boxed{1.3\times10^3\ \text{W}/\text{m}^2}$.

(*b*) Use Eq. 44-1 to find the intrinsic luminosity.

$$b = \frac{L}{4\pi d^2} \quad \rightarrow \quad L = 4\pi d^2 b = 4\pi\left(1.496\times10^{11}\,\text{m}^2\right)^2\left(1.3\times10^3\ \text{W}/\text{m}^2\right) = \boxed{3.7\times10^{26}\,\text{W}}$$

9. The density is the mass divided by the volume.

$$\rho = \frac{M}{V} = \frac{M}{\frac{4}{3}\pi r^3} = \frac{1.99\times10^{30}\,\text{kg}}{\frac{4}{3}\pi\left(6\times10^{10}\,\text{m}\right)^3} = \boxed{2\times10^{-3}\ \text{kg}/\text{m}^3}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

10. The angular width is the inverse tangent of the diameter of our Galaxy divided by the distance to the nearest galaxy. According to Figure 44-2, our Galaxy is about 100,000 ly in diameter.

$$\phi = \tan^{-1}\frac{\text{Galaxy diameter}}{\text{Distance to nearest galaxy}} = \tan^{-1}\frac{1.0\times10^5\,\text{ly}}{2.4\times10^6\,\text{ly}} = \boxed{0.042\,\text{rad}} \approx 2.4^\circ$$

$$\phi_{\text{Moon}} = \tan^{-1}\frac{\text{Moon diameter}}{\text{Distance to Moon}} = \tan^{-1}\frac{3.48\times10^6\,\text{m}}{3.84\times10^8\,\text{m}} = \boxed{9.1\times10^{-3}\,\text{rad}} \approx 0.52^\circ$$

The Galaxy width is about 4.5 times the Moon width.

11. The *Q*-value is the mass energy of the reactants minus the mass energy of the products. The masses are found in Appendix F.

$${}^4_2\text{He} + {}^4_2\text{He} \rightarrow {}^8_4\text{Be}$$

$$Q = 2m_{\text{He}}c^2 - m_{\text{Be}}c^2 = \left[2\left(4.002603\,\text{u}\right) - 8.005305\,\text{u}\right]c^2\left(931.5\,\text{Mev}/c^2\right) = \boxed{-0.092\,\text{MeV}}$$

$${}^4_2\text{He} + {}^8_4\text{Be} \rightarrow {}^{12}_6\text{C}$$

$$Q = m_{\text{Be}}c^2 + m_{\text{He}}c^2 - m_{\text{C}}c^2 = \left[4.002603\,\text{u} + 8.005305\,\text{u} - 12.000000\right]c^2\left(931.5\,\text{Mev}/c^2\right)$$

$$= \boxed{7.366\,\text{MeV}}$$

12. The angular width is the inverse tangent of the diameter of the Moon divided by the distance to the Sun.

$$\phi = \tan^{-1}\frac{\text{Moon diameter}}{\text{Distance to Sun}} = \tan^{-1}\frac{3.48\times10^6\,\text{m}}{1.496\times10^{11}\,\text{m}} = \boxed{2.33\times10^{-5}\,\text{rad}} \approx \left(1.33\times10^{-3}\right)^\circ \approx 4.79''$$

13. The density is the mass divided by the volume.

$$\rho = \frac{M}{V} = \frac{M_{\text{Sun}}}{\frac{4}{3}\pi R_{\text{Earth}}^3} = \frac{1.99\times10^{30}\,\text{kg}}{\frac{4}{3}\pi\left(6.38\times10^6\,\text{m}\right)^3} = \boxed{1.83\times10^9\ \text{kg}/\text{m}^3}$$

Since the volumes are the same, the ratio of the densities is the same as the ratio of the masses.

$$\frac{\rho}{\rho_{\text{Earth}}} = \frac{M}{M_{\text{Earth}}} = \frac{1.99\times10^{30}\,\text{kg}}{5.98\times10^{24}\,\text{kg}} = \boxed{3.33\times10^5\ \text{times larger}}$$

14. The density of the neutron star is its mass divided by its volume. Use the proton to calculate the density of nuclear matter. The radius of the proton is taken from Eq. 41-1.

$$\rho_{\substack{\text{neutron}\\\text{star}}} = \frac{M}{V} = \frac{1.5\left(1.99\times10^{30}\,\text{kg}\right)}{\frac{4}{3}\pi\left(11\times10^3\,\text{m}\right)^3} = 5.354\times10^{17}\ \text{kg}/\text{m}^3 \approx \boxed{5.4\times10^{17}\ \text{kg}/\text{m}^3}$$

$$\frac{\rho_{\substack{\text{neutron}\\\text{star}}}}{\rho_{\substack{\text{white}\\\text{dwarf}}}} = \frac{5.354\times10^{17}\ \text{kg}/\text{m}^3}{1.83\times10^9\ \text{kg}/\text{m}^3} = \boxed{2.9\times10^8} \qquad \frac{\rho_{\substack{\text{neutron}\\\text{star}}}}{\rho_{\substack{\text{nuclear}\\\text{matter}}}} = \frac{5.354\times10^{17}\ \text{kg}/\text{m}^3}{\frac{1.673\times10^{-27}\,\text{kg}}{\frac{4}{3}\pi\left(1.2\times10^{-15}\,\text{m}\right)^3}} = \boxed{2.3}$$

15. Wien's law (Eq. 37-1) says that the $\lambda_p T = \alpha$, where α is a constant, and so $\lambda_{p1} T_1 = \lambda_{p2} T_2$. The Stefan–Boltzmann equation (Eq. 19-17) says that the power output of a star is given by $P = \beta A T^4$, where β is a constant, and *A* is the radiating area. The *P* in the Stefan–Boltzmann equation is the same as the luminosity *L* in this chapter. The luminosity *L* is related to the apparent brightness *b* by Eq. 44-1. It is given that $b_1/b_2 = 0.091$, $d_1 = d_2$, $\lambda_{p1} = 470\,\text{nm}$, and $\lambda_{p2} = 720\,\text{nm}$.

$$\lambda_{p1} T_1 = \lambda_{p2} T_2 \quad \rightarrow \quad \frac{T_2}{T_1} = \frac{\lambda_{p1}}{\lambda_{p2}} \quad ; \quad b_1 = 0.091 b_2 \quad \rightarrow \quad \frac{L_1}{4\pi d_1^2} = 0.091 \frac{L_2}{4\pi d_2^2} \quad \rightarrow$$

$$1 = \frac{d_2^2}{d_1^2} = \frac{0.091 L_2}{L_1} = \frac{0.091 P_2}{P_1} = \frac{0.091 A_2 T_2^4}{A_1 T_1^4} = \frac{(0.091) 4\pi r_2^2 T_2^4}{4\pi r_1^2 T_1^4} = 0.091 \frac{T_2^4}{T_1^4} \frac{r_2^2}{r_1^2} \quad \rightarrow$$

$$\frac{r_1}{r_2} = \sqrt{0.091} \left(\frac{T_2}{T_1} \right)^2 = \sqrt{0.091} \left(\frac{\lambda_{p2}}{\lambda_{p1}} \right)^2 = \sqrt{0.091} \left(\frac{470\,\text{nm}}{720\,\text{nm}} \right)^2 = 0.1285$$

The ratio of the diameters is the same as the ratio of radii, so $\frac{D_1}{D_2} = \boxed{0.13}$.

16. Wien's law (Eq. 37-1) says that the $\lambda_p T = \alpha$, where α is a constant, and so $\lambda_{p1} T_1 = \lambda_{p2} T_2$. The Stefan–Boltzmann equation (Eq. 19-17) says that the power output of a star is given by $P = \beta A T^4$, where β is a constant, and *A* is the radiating area. The *P* in the Stefan–Boltzmann equation is the same as the luminosity *L* in this chapter. The luminosity *L* is related to the apparent brightness *b* by Eq. 44-1. It is given that $b_1 = b_2$, $r_1 = r_2$, $\lambda_{p1} = 750\,\text{nm}$, and $\lambda_{p2} = 450\,\text{nm}$.

$$\lambda_{p1} T_1 = \lambda_{p2} T_2 \quad \rightarrow \quad \frac{T_2}{T_1} = \frac{\lambda_{p1}}{\lambda_{p2}}$$

$$b_1 = b_2 \quad \rightarrow \quad \frac{L_1}{4\pi d_1^2} = \frac{L_2}{4\pi d_2^2} \quad \rightarrow \quad \frac{d_2^2}{d_1^2} = \frac{L_2}{L_1} = \frac{P_2}{P_1} = \frac{\beta A_2 T_2^4}{\beta A_1 T_1^4} = \frac{4\pi r_2^2 T_2^4}{4\pi r_1^2 T_1^4} = \frac{T_2^4}{T_1^4} = \left(\frac{T_2}{T_1} \right)^4 \quad \rightarrow$$

$$\frac{d_2}{d_1} = \left(\frac{T_2}{T_1} \right)^2 = \left(\frac{\lambda_{p1}}{\lambda_{p2}} \right)^2 = \left(\frac{750}{450} \right)^2 = 2.8$$

The star with the peak at 450 nm is 2.8 times further away than the star with the peak at 750 nm.

17. The Schwarzschild radius is $\frac{2GM}{c^2}$.

$$R_{\text{Earth}} = \frac{2GM_{\text{Earth}}}{c^2} = \frac{2\left(6.67 \times 10^{-11}\,\text{N} \cdot \text{m}^2/\text{kg}^2\right)\left(5.98 \times 10^{24}\,\text{kg}\right)}{\left(3.00 \times 10^8\,\text{m/s}\right)^2} = 8.86 \times 10^{-3}\,\text{m} \approx \boxed{8.9\,\text{mm}}$$

18. The Schwarzschild radius is given by $R = \frac{2GM}{c^2}$. An approximate mass for our Galaxy is calculated in Example 44-1.

$$R = \frac{2GM}{c^2} = \frac{2\left(6.67 \times 10^{-11}\,\text{N} \cdot \text{m}^2/\text{kg}^2\right)\left(2 \times 10^{41}\,\text{kg}\right)}{\left(3.00 \times 10^8\,\text{m/s}\right)^2} = \boxed{3 \times 10^{14}\,\text{m}}$$

19. The limiting value for the angles in a triangle on a sphere is $\boxed{540^\circ}$. Imagine drawing an equilateral triangle near the north pole, enclosing the north pole. If that triangle were small, the surface would be approximately flat, and each angle in the triangle would be 60°. Then imagine "stretching" each side of that triangle down towards the equator, while keeping sure that the north pole stayed inside the triangle. The angle at each vertex of the triangle would expand, with a limiting value of 180°. The three 180° angles in the triangle would sum to 540°.

20. To just escape from an object, the kinetic energy of the body at the surface of the body must be equal to the magnitude of the gravitational potential energy at the surface. Use Eq. 8-19.

$$v_{\text{esc}} = \sqrt{\frac{2GM}{R_{\text{Schwarzchild}}}} = \sqrt{\frac{2GM}{2GM/c^2}} = \boxed{c}$$

21. We find the time for the light to cross the elevator, and then find how far the elevator moves during that time due to its acceleration.

$$\Delta t = \frac{\Delta x}{c} \; ; \Delta y = \tfrac{1}{2} g (\Delta t)^2 = \frac{g(\Delta x)^2}{2c^2} = \frac{(9.80\,\text{m/s}^2)(2.4\,\text{m})}{2(3.00\times10^8\,\text{m/s})^2} = \boxed{1.3\times10^{-16}\,\text{m}}$$

Note that this is smaller than the size of a proton.

22. Use Eq. 44-4, Hubble's law.

$$v = Hd \;\rightarrow\; d = \frac{v}{H} = \frac{1850\,\text{km/s}}{22\,\text{km/s/Mly}} = \boxed{84\,\text{Mly}} = 8.4\times10^7\,\text{ly}$$

23. Use Eq. 44-4, Hubble's law.

$$v = Hd \;\rightarrow\; d = \frac{v}{H} = \frac{(0.015)(3.00\times10^8\,\text{m/s})}{2.2\times10^4\,\text{m/s/Mly}} = 204.5\,\text{Mly} \approx \boxed{2.0\times10^2\,\text{Mly}} = 2.0\times10^8\,\text{ly}$$

24. (*a*) Use Eq. 44-6 to solve for the speed of the galaxy.

$$z = \frac{\lambda_{\text{obs}} - \lambda_{\text{rest}}}{\lambda_{\text{rest}}} \approx \frac{v}{c} \;\rightarrow\; v = c\left(\frac{455\,\text{nm} - 434\,\text{nm}}{434\,\text{nm}}\right) = 0.04839c \approx \boxed{0.048c}$$

(*b*) Use Hubble's law, Eq. 44-4, to solve for the distance.

$$v = Hd \;\rightarrow\; d = \frac{v}{H} = \frac{0.04839(3.00\times10^8\,\text{m/s})}{22000\,\text{m/s/Mly}} = 660\,\text{Mly} \approx \boxed{6.6\times10^8\,\text{ly}}$$

25. We find the velocity from Hubble's law, Eq. 44-4, and the observed wavelength from the Doppler shift, Eq. 44-3.

(*a*) $$\frac{v}{c} = \frac{Hd}{c} = \frac{(22000\,\text{m/s/Mly})(7.0\,\text{Mly})}{3.00\times10^8\,\text{m/s}} = 5.133\times10^{-4}$$

$$\lambda = \lambda_0\sqrt{\frac{1+v/c}{1-v/c}} = (656\,\text{nm})\sqrt{\frac{1+5.133\times10^{-4}}{1-5.133\times10^{-4}}} = 656.34\,\text{nm} \approx \boxed{656\,\text{nm}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) $\dfrac{v}{c} = \dfrac{Hd}{c} = \dfrac{(22000\,\text{m/s/Mly})(70\,\text{Mly})}{3.00\times10^8\,\text{m/s}} = 5.133\times10^{-3}$

$$\lambda = \lambda_0\sqrt{\frac{1+v/c}{1-v/c}} = (656\,\text{nm})\sqrt{\frac{1+5.133\times10^{-3}}{1-5.133\times10^{-3}}} = 659.38\,\text{nm} \approx \boxed{659\,\text{nm}}$$

26. Use Eqs. 44-3 and 44-4 to solve for the distance to the galaxy.

$$\lambda_{\text{obs}} = \lambda_{\text{rest}}\sqrt{\frac{1+v/c}{1-v/c}} \quad\rightarrow\quad v = c\frac{\left(\lambda_{\text{obs}}^2 - \lambda_{\text{rest}}^2\right)}{\left(\lambda_{\text{obs}}^2 + \lambda_{\text{rest}}^2\right)}$$

$$d = \frac{v}{H} = \frac{c}{H}\frac{\left(\lambda_{\text{obs}}^2 - \lambda_{\text{rest}}^2\right)}{\left(\lambda_{\text{obs}}^2 + \lambda_{\text{rest}}^2\right)} = \frac{\left(3.00\times10^8\,\text{m/s}\right)}{\left(2.2\times10^4\,\text{m/s/Mly}\right)}\frac{\left[(423.4\,\text{nm})^2 - (393.4\,\text{nm})^2\right]}{\left[(423.4\,\text{nm})^2 + (393.4\,\text{nm})^2\right]}$$

$$= 1.0\times10^3\,\text{Mly} = \boxed{1.0\times10^9\,\text{ly}}$$

27. Use Eqs. 44-3 and 44-5a to solve for the speed of the galaxy.

$$z = \frac{\lambda_{\text{obs}} - \lambda_{\text{rest}}}{\lambda_{\text{rest}}} = \frac{\lambda_{\text{obs}}}{\lambda_{\text{rest}}} - 1 = \sqrt{\frac{1+v/c}{1-v/c}} - 1 \quad\rightarrow$$

$$\frac{v}{c} = \frac{(z+1)^2 - 1}{(z+1)^2 + 1} = \frac{1.060^2 - 1}{1.060^2 + 1} = 0.05820 \quad\rightarrow\quad v = \boxed{0.058c}$$

The approximation of Eq. 44-6 gives $v = zc = \boxed{0.060c}$.

28. Use Eqs. 44-3 and 44-5a to solve for the redshift parameter.

$$z = \frac{\lambda_{\text{obs}} - \lambda_{\text{rest}}}{\lambda_{\text{rest}}} = \frac{\lambda_{\text{obs}}}{\lambda_{\text{rest}}} - 1 = \sqrt{\frac{1+v/c}{1-v/c}} - 1 = \sqrt{\frac{1+0.075}{1-0.075}} - 1 = \boxed{0.078}$$

Or, we use the approximation given in Eq. 44-6.

$$z \approx \frac{v}{c} = \boxed{0.075}$$

29. Eq. 44-3 states $\lambda = \lambda_{\text{rest}}\sqrt{\dfrac{1+v/c}{1-v/c}}$.

$$\lambda = \lambda_{\text{rest}}\sqrt{\frac{1+v/c}{1-v/c}} = \lambda_{\text{rest}}\left(1+\frac{v}{c}\right)^{1/2}\left(1-\frac{v}{c}\right)^{-1/2} \approx \lambda_{\text{rest}}\left(1+\tfrac{1}{2}\frac{v}{c}\right)\left(1-\left(-\tfrac{1}{2}\right)\frac{v}{c}\right) = \lambda_{\text{rest}}\left(1+\tfrac{1}{2}\frac{v}{c}\right)^2$$

$$\lambda \approx \lambda_{\text{rest}}\left(1+2\left(\tfrac{1}{2}\frac{v}{c}\right)\right) = \lambda_{\text{rest}}\left(1+\frac{v}{c}\right) = \lambda_{\text{rest}} + \lambda_{\text{rest}}\frac{v}{c} \quad\rightarrow\quad \lambda - \lambda_{\text{rest}} = \Delta\lambda = \lambda_{\text{rest}}\frac{v}{c} \quad\rightarrow\quad \boxed{\frac{\Delta\lambda}{\lambda_{\text{rest}}} = \frac{v}{c}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

30. For small relative wavelength shifts, we may use Eq. 44-6 to find the speed. We use Eq. 44-4 to find the distance.

$$\frac{v}{c} = \frac{\Delta\lambda}{\lambda_{\text{rest}}} \quad \rightarrow \quad v = c\frac{\Delta\lambda}{\lambda_{\text{rest}}} \; ; \; v = Hd \quad \rightarrow$$

$$d = \frac{v}{H} = \frac{c}{H}\frac{\Delta\lambda}{\lambda_{\text{rest}}} = \left(\frac{3.00\times10^{8}\,\text{m/s}}{22{,}000\,\text{m/s/Mly}}\right)\left(\frac{0.10\,\text{cm}}{21\,\text{cm}}\right) = \boxed{65\,\text{Mly}}$$

31. Wien's law is given in Eq. 37-1.

$$\lambda_{\text{p}}T = 2.90\times10^{-3}\,\text{m•K} \quad \rightarrow \quad \lambda_{\text{p}} = \frac{2.90\times10^{-3}\,\text{m•K}}{T} = \frac{2.90\times10^{-3}\,\text{m•K}}{2.7\,\text{K}} = \boxed{1.1\times10^{-3}\,\text{m}}$$

32. We use Wien's law, Eq. 37-1. From Figure 44-30, the temperature is about 10^{10} K.

$$\lambda_{\text{p}}T = 2.90\times10^{-3}\,\text{m•K} \quad \rightarrow \quad \lambda_{\text{p}} = \frac{2.90\times10^{-3}\,\text{m•K}}{T} = \frac{2.90\times10^{-3}\,\text{m•K}}{10^{10}\,\text{K}} \succ= \boxed{3\times10^{-13}\,\text{m}}$$

From Figure 31-12, that wavelength is in the gamma ray region of the EM spectrum.

33. We use the proton as typical nuclear matter.

$$\left(10^{-26}\,\frac{\text{kg}}{\text{m}^3}\right)\left(\frac{1\,\text{nucleon}}{1.67\times10^{-27}\,\text{kg}}\right) = \boxed{6\,\text{nucleons/m}^3}$$

34. If the universe's scale is inversely proportional to the temperature, the scale times the temperature should be constant. If we call the current scale "1," and knowing the current temperature to be about 3 K, then the product of scale and temperature should be about 3. Use Figure 44-30 to estimate the temperature at various times. For purposes of illustration, we assume the universe has a current size of about 10^{10} ly. There will be some variation in the answer due to reading the figure.

(*a*) At $t = 10^{6}$ yr, the temperature is about 1000 K. Thus the scale is found as follows.

$$(\text{Scale})(\text{Temperature}) = 3 \quad \rightarrow \quad \text{Scale} = \frac{3}{\text{Temperature}} = \frac{3}{1000} = \boxed{3\times10^{-3}} \quad \rightarrow$$

$$\text{Size} \approx \left(3\times10^{-3}\right)\left(10^{10}\,\text{ly}\right) = \boxed{3\times10^{7}\,\text{ly}}$$

(*b*) At $t = 1$ s, the temperature is about 10^{10} K.

$$\text{Scale} = \frac{3}{\text{Temperature}} = \frac{3}{10^{10}} = \boxed{3\times10^{-10}} \quad \rightarrow \quad \text{Size} \approx \left(3\times10^{-10}\right)\left(10^{10}\,\text{ly}\right) = \boxed{3\,\text{ly}}$$

(*c*) At $t = 10^{-6}$ s, the temperature is about 10^{13} K.

$$\text{Scale} = \frac{3}{\text{Temperature}} = \frac{3}{10^{13}} = \boxed{3\times10^{-13}} \quad \rightarrow$$

$$\text{Size} \approx \left(3\times10^{-13}\right)\left(10^{10}\,\text{ly}\right) = \boxed{3\times10^{-3}\,\text{ly}} \approx 3\times10^{13}\,\text{m}$$

(*d*) At $t = 10^{-35}$ s, the temperature is about 10^{27} K.

$$\text{Scale} = \frac{3}{\text{Temperature}} = \frac{3}{10^{27}} = \boxed{3\times10^{-27}}$$

$$\text{Size} \approx \left(3\times10^{-27}\right)\left(10^{10}\,\text{ly}\right) = 3\times10^{-17}\,\text{ly} \approx \boxed{0.3\,\text{m}}$$

35. We approximate the temperature–energy relationship by $kT = E = mc^2$ as suggested on page 1217.

$$kT = mc^2 \quad \rightarrow \quad T = \frac{mc^2}{k}.$$

(*a*) $$T = \frac{mc^2}{k} = \frac{\left(500\,\text{MeV}/c^2\right)c^2\left(1.60\times10^{-13}\,\text{J/MeV}\right)}{1.38\times10^{-23}\,\text{J/K}} = 6\times10^{12}\,\text{K}$$

From Figure 44-30, this corresponds to a time of $\boxed{\sim 10^{-5}\,\text{s}}$.

(*b*) $$T = \frac{mc^2}{k} = \frac{\left(9500\,\text{MeV}/c^2\right)c^2\left(1.60\times10^{-13}\,\text{J/MeV}\right)}{1.38\times10^{-23}\,\text{J/K}} = 1\times10^{14}\,\text{K}$$

From Figure 44-30, this corresponds to a time of $\boxed{\sim 10^{-7}\,\text{s}}$.

(*c*) $$T = \frac{mc^2}{k} = \frac{\left(100\,\text{MeV}/c^2\right)c^2\left(1.60\times10^{-13}\,\text{J/MeV}\right)}{1.38\times10^{-23}\,\text{J/K}} = 1\times10^{12}\,\text{K}$$

From Figure 44-30, this corresponds to a time of $\boxed{\sim 10^{-4}\,\text{s}}$.

There will be some variation in the answers due to reading the figure.

36. (*a*) According to the text, near Figure 44-33, the visible matter makes up about one-tenth of the total baryonic matter. The average baryonic density is therefore 10 times the density of visible matter.

$$\rho_{\text{baryon}} = 10\rho_{\text{visible}} = 10\frac{M_{\text{visible}}}{\frac{4}{3}\pi R^3}$$

$$= 10\frac{\left(10^{11}\,\text{galaxies}\right)\left(10^{11}\,\text{stars/galaxy}\right)\left(2.0\times10^{30}\,\text{kg/star}\right)}{\frac{4}{3}\pi\left[\left(14\times10^{9}\,\text{ly}\right)\left(9.46\times10^{15}\,\text{m/ly}\right)\right]^3}$$

$$= 2.055\times10^{-26}\,\text{kg/m}^3 \approx \boxed{2.1\times10^{-26}\,\text{kg/m}^3}$$

(*b*) Again, according to the text, dark matter is about 4 times more plentiful than normal matter.

$$\rho_{\text{dark}} = 4\rho_{\text{baryon}} = 4\left(2.055\times10^{-26}\,\text{kg/m}^3\right) \approx \boxed{8.2\times10^{-26}\,\text{kg/m}^3}$$

37. (*a*) From page 1201, a white dwarf with a mass equal to that of the Sun has a radius about the size of the Earth's radius, $\boxed{6380\,\text{km}}$. From page 1202, a neutron star with a mass equal to 1.5 solar masses has a radius of about $\boxed{20\,\text{km}}$. For the black hole, we use the Schwarzschild radius formula.

$$R = \frac{2GM}{c^2} = \frac{2\left(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)3\left(1.99\times10^{30}\,\text{kg}\right)}{\left(3.00\times10^{8}\,\text{m/s}\right)^2} = 8849\text{m} \approx \boxed{8.85\,\text{km}}$$

(*b*) The ratio is $6380 : 20 : 8.85 = 721 : 2.26 : 1 \approx \boxed{700 : 2 : 1}$.

38. The angular momentum is the product of the rotational inertia and the angular velocity.

$$(I\omega)_{\text{initial}} = (I\omega)_{\text{final}} \quad \rightarrow$$

$$\omega_{\text{final}} = \omega_{\text{initial}}\left(\frac{I_{\text{initial}}}{I_{\text{final}}}\right) = \omega_{\text{initial}}\left(\frac{\frac{2}{5}MR^2_{\text{initial}}}{\frac{2}{5}MR^2_{\text{final}}}\right) = \omega_{\text{initial}}\left(\frac{R_{\text{initial}}}{R_{\text{final}}}\right)^2 = (1\,\text{rev/month})\left(\frac{7\times10^8\,\text{m}}{8\times10^3\,\text{m}}\right)^2$$

$$= 7.66\times10^9\ \text{rev/month} = 7.66\times10^9\,\frac{\text{rev}}{\text{month}}\times\frac{1\,\text{month}}{30\,\text{d}}\times\frac{1\,\text{d}}{24\,\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}} = 2953\,\text{rev/s}$$

$$\approx \boxed{3000\,\text{rev/s}}$$

39. The rotational kinetic energy is given by $\frac{1}{2}I\omega^2$. The final angular velocity, from problem 43, is 7.66×10^9 rev/month.

$$\frac{K_{\text{final}}}{K_{\text{initial}}} = \frac{\frac{1}{2}I_{\text{final}}\omega^2_{\text{final}}}{\frac{1}{2}I_{\text{initial}}\omega^2_{\text{initial}}} = \frac{\frac{2}{5}MR^2_{\text{final}}\omega^2_{\text{final}}}{\frac{2}{5}MR^2_{\text{initial}}\omega^2_{\text{initial}}} = \left(\frac{R_{\text{final}}\omega_{\text{final}}}{R_{\text{initial}}\omega_{\text{initial}}}\right)^2$$

$$= \left(\frac{(8\times10^3\,\text{m})(7.66\times10^9\ \text{rev/month})}{(7\times10^8\,\text{m})(1\,\text{rev/month})}\right)^2 = \boxed{8\times10^9}$$

40. The apparent luminosity is given by Eq. 44-1. Use that relationship to derive an expression for the absolute luminosity, and equate that for two stars.

$$b = \frac{L}{4\pi d^2} \quad \rightarrow \quad L = 4\pi d^2 b$$

$$L_{\substack{\text{distant}\\\text{star}}} = L_{\text{Sun}} \quad \rightarrow \quad 4\pi d^2_{\substack{\text{distant}\\\text{star}}} b_{\substack{\text{distant}\\\text{star}}} = 4\pi d^2_{\text{Sun}} b_{\text{Sun}} \quad \rightarrow$$

$$d_{\substack{\text{distant}\\\text{star}}} = d_{\text{Sun}}\sqrt{\frac{l_{\text{Sun}}}{l_{\substack{\text{distant}\\\text{star}}}}} = (1.5\times10^{11}\,\text{m})\sqrt{\frac{1}{10^{-11}}}\left(\frac{1\,\text{ly}}{9.461\times10^{15}\,\text{m}}\right) = \boxed{5\,\text{ly}}$$

41. A: The temperature increases, the luminosity stays the same, and the size decreases.
B: The temperature stays the same, the luminosity decreases, and the size decreases.
C: The temperature decreases, the luminosity increases, and the size increases.

42. The power output is the energy loss divided by the elapsed time.

$$P = \frac{\Delta K}{\Delta t} = \frac{K_{\text{initial}}(\text{fraction lost})}{\Delta t} = \frac{\frac{1}{2}I\omega^2(\text{fraction lost})}{\Delta t} = \frac{\frac{1}{2}\frac{2}{5}MR^2\omega^2(\text{fraction lost})}{\Delta t}$$

$$= \frac{1}{5}\frac{(1.5)(1.99\times10^{30}\,\text{kg})(8.0\times10^3\,\text{m})^2(2\pi\,\text{rad/s})^2(1\times10^{-9})}{(1\,\text{d})(24\,\text{h/d})(3600\,\text{s/h})} = 1.74610^{25}\,\text{W} \approx \boxed{1.7\times10^{25}\,\text{W}}$$

43. Use Newton's law of universal gravitation.

$$F = G\frac{m_1m_2}{r^2} = (6.67\times10^{-11}\ \text{N•m}^2/\text{kg}^2)\frac{(3\times10^{41}\,\text{kg})^2}{\left[(2\times10^6\,\text{ly})(9.46\times10^{15}\,\text{m/ly})\right]^2} = 1.68\times10^{28}\,\text{N}$$

$$\approx \boxed{2\times10^{28}\,\text{N}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

44. (*a*) Assume that the nucleons make up only 2% of the critical mass density.

$$\text{nucleon mass density} = 0.02\left(10^{-26}\ \text{kg/m}^3\right)$$

$$\text{nucleon number density} = \frac{0.02\left(10^{-26}\ \text{kg/m}^3\right)}{1.67\times10^{-27}\ \text{kg/nucleon}} = 0.12\ \text{nucleon/m}^3$$

$$\text{neutrino number density} = 10^9\left(\text{nucleon number density}\right) = 1.2\times10^8\ \text{neutrino/m}^3$$

$$\frac{0.98\left(10^{-26}\ \text{kg/m}^3\right)}{1.2\times10^8\ \text{neutrino/m}^3} = 8.17\times10^{-35}\ \frac{\text{kg}}{\text{neutrino}} \times \frac{9.315\times10^8\ \text{eV}/c^2}{1.66\times10^{-27}\ \text{kg}} = \boxed{46\ \text{eV}/c^2}$$

(*b*) Assume that the nucleons make up only 5% of the critical mass density.

$$\text{nucleon mass density} = 0.05\left(10^{-26}\ \text{kg/m}^3\right)$$

$$\text{nucleon number density} = \frac{0.05\left(10^{-26}\ \text{kg/m}^3\right)}{1.67\times10^{-27}\ \text{kg/nucleon}} = 0.30\ \text{nucleon/m}^3$$

$$\text{neutrino number density} = 10^9\left(\text{nucleon number density}\right) = 3.0\times10^8\ \text{neutrino/m}^3$$

$$\frac{0.95\left(10^{-26}\ \text{kg/m}^3\right)}{3.0\times10^8\ \text{neutrino/m}^3} = 3.17\times10^{-35}\ \frac{\text{kg}}{\text{neutrino}} \times \frac{9.315\times10^8\ \text{eV}/c^2}{1.66\times10^{-27}\ \text{kg}} = \boxed{18\ \text{eV}/c^2}$$

45. The temperature of each star can be found from Wien's law.

$$\lambda_p T = 2.90\times10^{-3}\ \text{m•K} \ \rightarrow$$

$$T_{660} = \frac{2.90\times10^{-3}\ \text{m•K}}{660\times10^{-9}\ \text{m}} = 4390\ \text{K} \qquad T_{480} = \frac{2.90\times10^{-3}\ \text{m•K}}{480\times10^{-9}\ \text{m}} = 6040\ \text{K}$$

The luminosity of each star can be found from the H–R diagram.

$$L_{660} \approx 3\times10^{25}\ \text{W} \qquad L_{480} \approx 3\times10^{26}\ \text{W}$$

The Stefan–Boltzmann equation says that the power output of a star is given by $P = \beta A T^4$, where β is a constant, and *A* is the radiating area. The *P* in the Stefan–Boltzmann equation is the same as the luminosity *L* given in Eq. 44-1. Form the ratio of the two luminosities.

$$\frac{L_{480}}{L_{660}} = \frac{\beta A_{480} T_{480}^4}{\beta A_{660} T_{660}^4} = \frac{4\pi r_{480}^2 T_{480}^4}{4\pi r_{660}^2 T_{660}^4} \ \rightarrow \ \frac{r_{480}}{r_{660}} = \sqrt{\frac{L_{480}}{L_{660}}}\frac{T_{660}^2}{T_{480}^2} = \sqrt{\frac{3\times10^{26}\ \text{W}}{3\times10^{25}\ \text{W}}}\frac{\left(4390\ \text{K}\right)^2}{\left(6040\ \text{K}\right)^2} = 1.67$$

The diameters are in the same ratio as the radii.

$$\frac{d_{480}}{d_{660}} = 1.67 \approx \boxed{1.7}$$

The luminosities are fairly subjective, since they are read from the H–R diagram. Different answers may arise from different readings of the H–R diagram.

46. (*a*) The number of parsecs is the reciprocal of the angular resolution in seconds of arc.

$$100\ \text{parsec} = \frac{1}{\phi''} \ \rightarrow \ \phi = \left(0.01''\right)\left(\frac{1'}{60''}\right)\left(\frac{1^\circ}{60'}\right) = \left(2.78\times10^{-6}\right)^\circ \approx \boxed{\left(3\times10^{-6}\right)^\circ}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

(*b*) We use the Rayleigh criterion, Eq. 35-10, which relates the angular resolution to the diameter of the optical element. We choose a wavelength of 550 nm, in the middle of the visible range.

$$\theta = \frac{1.22\lambda}{D} \quad \rightarrow \quad D = \frac{1.22\lambda}{\theta} = \frac{1.22\left(550\times10^{-9}\,\text{m}\right)}{\left[\left(2.78\times10^{-6}\right)^\circ\right]\left(\pi\,\text{rad}/180^\circ\right)} = 13.83\,\text{m} \approx \boxed{14\,\text{m}}$$

The largest optical telescopes currently in use are about 10 m in diameter.

47. We approximate the temperature–kinetic energy relationship by $kT = K$ as given on page 1217.

$$kT = K \quad \rightarrow \quad T = \frac{K}{k} = \frac{\left(1.96\times10^{12}\,\text{eV}\right)\left(1.60\times10^{-19}\,\text{J/eV}\right)}{1.38\times10^{-23}\,\text{J/K}} = \boxed{2\times10^{16}\,\text{K}}$$

From Figure 44-30, this is in the hadron era.

48. We assume that gravity causes a centripetal force on the gas. Solve for the speed of the rotating gas, and use Eq. 44-6.

$$F_{\text{gravity}} = F_{\text{centripetal}} \quad \rightarrow \quad G\frac{m_{\text{gas}}m_{\substack{\text{black}\\\text{hole}}}}{r^2} = \frac{m_{\text{gas}}v_{\text{gas}}^2}{r} \quad \rightarrow$$

$$v_{\text{gas}} = \sqrt{G\frac{m_{\substack{\text{black}\\\text{hole}}}}{r}} = \sqrt{\left(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\frac{\left(2\times10^9\right)\left(1.99\times10^{30}\,\text{kg}\right)}{\left(68\,\text{ly}\right)\left(\dfrac{9.46\times10^{15}\,\text{m}}{1\,\text{ly}}\right)}} = 6.42\times10^5\,\text{m/s}$$

$$z \approx \frac{v}{c} = \frac{6.42\times10^5\,\text{m/s}}{3.00\times10^8\,\text{m/s}} = 2.14\times10^{-3} \approx \boxed{2\times10^{-3}}$$

49. (*a*) To find the energy released in the reaction, we calculate the *Q*-value for this reaction. From Eq. 42-2a, the *Q*-value is the mass energy of the reactants minus the mass energy of the products. The masses are found in Appendix F.

$$Q = 2m_{\text{C}}c^2 - m_{\text{Mg}}c^2 = \left[2\left(12.000000\,\text{u}\right) - 23.985042\,\text{u}\right]c^2\left(931.5\,\text{Mev}/c^2\right) = \boxed{13.93\,\text{MeV}}$$

(*b*) The total kinetic energy should be equal to the electrical potential energy of the two nuclei when they are just touching. The distance between the two nuclei will be twice the nuclear radius, from Eq. 41-1. Each nucleus will have half the total kinetic energy.

$$r = \left(1.2\times10^{-15}\,\text{m}\right)\left(A\right)^{1/3} = \left(1.2\times10^{-15}\,\text{m}\right)\left(12\right)^{1/3} \qquad U = \frac{1}{4\pi\varepsilon_0}\frac{q_{\text{nucleus}}^2}{2r}$$

$$K = \tfrac{1}{2}U = \tfrac{1}{2}\frac{1}{4\pi\varepsilon_0}\frac{q_{\text{nucleus}}^2}{2r}$$

$$= \tfrac{1}{2}\left(8.988\times10^9\,\text{N}\cdot\text{n}^2/\text{C}^2\right)\frac{\left(6\right)^2\left(1.60\times10^{-19}\,\text{C}\right)^2}{2\left(1.2\times10^{-15}\,\text{m}\right)\left(12\right)^{1/3}}\left(\frac{1\,\text{MeV}}{1.60\times10^{-13}\,\text{J}}\right) = 4.711\,\text{MeV}$$

$$\approx \boxed{4.7\,\text{MeV}}$$

(*c*) We approximate the temperature–kinetic energy relationship by $kT = K$ as given on page 1217.

$$kT = K \quad \rightarrow \quad T = \frac{K}{k} = \frac{\left(4.711\,\text{MeV}\right)\left(1.60\times10^{-13}\,\text{J/MeV}\right)}{1.38\times10^{-23}\,\text{J/K}} = \boxed{5.5\times10^{10}\,\text{K}}$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

50. (*a*) Find the *Q*-value for this reaction. From Eq. 42-2a, the *Q*-value is the mass energy of the reactants minus the mass energy of the products.

$${}^{16}_{8}\text{O} + {}^{16}_{8}\text{O} \rightarrow {}^{28}_{14}\text{Si} + {}^{4}_{2}\text{He}$$

$$Q = 2m_{\text{O}}c^2 - m_{\text{Si}}c^2 - m_{\text{He}}c^2 = \left[2\left(15.994915\,\text{u}\right) - 27.976927\,\text{u} - 4.002603\right]c^2\left(931.5\,\text{Mev}/c^2\right)$$

$$= \boxed{9.594\,\text{MeV}}$$

(*b*) The total kinetic energy should be equal to the electrical potential energy of the two nuclei when they are just touching. The distance between the two nuclei will be twice the nuclear radius, from Eq. 41-1. Each nucleus will have half the total kinetic energy.

$$r = \left(1.2\times10^{-15}\,\text{m}\right)\left(A\right)^{1/3} = \left(1.2\times10^{-15}\,\text{m}\right)\left(16\right)^{1/3} \qquad U = \frac{1}{4\pi\varepsilon_0}\frac{q_{\text{nucleus}}^2}{2r}$$

$$K_{\text{nucleus}} = \tfrac{1}{2}U = \tfrac{1}{2}\frac{1}{4\pi\varepsilon_0}\frac{q_{\text{nucleus}}^2}{2r}$$

$$= \tfrac{1}{2}\left(8.988\times10^{9}\ \text{N}\bullet\text{n}^2/\text{C}^2\right)\frac{\left(8\right)^2\left(1.60\times10^{-19}\,\text{C}\right)^2}{2\left(1.2\times10^{-15}\,\text{m}\right)\left(16\right)^{1/3}}\times\frac{1\,\text{eV}}{1.60\times10^{-19}\,\text{J}} = 7.609\,\text{MeV}$$

$$\approx \boxed{7.6\,\text{MeV}}$$

(*c*) We approximate the temperature–kinetic energy relationship by $kT = K$ as given on page 1217.

$$kT = K \rightarrow T = \frac{K}{k} = \frac{\left(7.609\times10^{6}\,\text{eV}\right)\left(\dfrac{1.60\times10^{-19}\,\text{J}}{1\,\text{eV}}\right)}{1.38\times10^{-23}\,\text{J/K}} = \boxed{8.8\times10^{10}\,\text{K}}$$

51. We treat the energy of the photon as a "rest mass," and so $m_{\text{photon}}\text{"} = \text{"}E_{\text{photon}}/c^2$. To just escape from a spherical mass *M* of radius *R*, the energy of the photon must be equal to the magnitude of the gravitational potential energy at the surface.

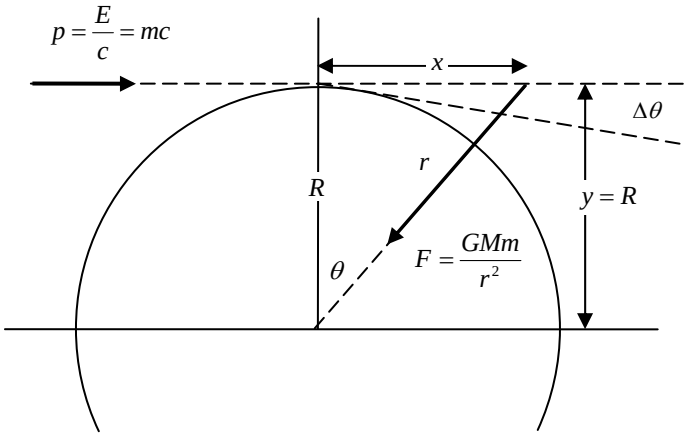
$$E_{\text{photon}} = \frac{GMm_{\text{photon}}}{R} \rightarrow R = \frac{GMm_{\text{photon}}}{E_{\text{photon}}} = \frac{GM\left(E_{\text{photon}}/c^2\right)}{E_{\text{photon}}} = \boxed{\frac{GM}{c^2}}$$

52. We use the Sun's mass and given density to calculate the size of the Sun.

$$\rho = \frac{M}{V} = \frac{M}{\frac{4}{3}\pi r_{\text{Sun}}^3} \rightarrow$$

$$r_{\text{Sun}} = \left(\frac{3M}{4\pi\rho}\right)^{1/3} = \left[\frac{3\left(1.99\times10^{30}\,\text{kg}\right)}{4\pi\left(10^{-26}\,\text{kg/m}^3\right)}\right]^{1/3} = 3.62\times10^{18}\,\text{m}\left(\frac{1\,\text{ly}}{9.46\times10^{15}\,\text{m}}\right) = 382\,\text{ly} \approx \boxed{400\,\text{ly}}$$

$$\frac{r_{\text{Sun}}}{d_{\text{Earth-Sun}}} = \frac{3.62\times10^{18}\,\text{m}}{1.50\times10^{11}\,\text{m}} \approx \boxed{2\times10^{7}} \ ; \ \frac{r_{\text{Sun}}}{d_{\text{galaxy}}} = \frac{382\,\text{ly}}{100{,}000\,\text{ly}} \approx \boxed{4\times10^{-3}}$$



© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

53. We approximate the temperature–kinetic energy relationship by $kT = K$ as given on page 1217.

$$kT = K \quad \rightarrow \quad T = \frac{K}{k} = \frac{\left(14\times10^{12}\text{eV}\right)\left(1.60\times10^{-19}\text{ J/eV}\right)}{1.38\times10^{-23}\text{ J/K}} = 1.6\times10^{17}\text{ K}$$

From Figure 44-30, this might correspond to a time around $\boxed{10^{-15}\text{s}}$. Note that this is just a very rough estimate due to the qualitative nature of Figure 44-30.

54. (a) We consider the photon as entering from the left, grazing the Sun, and moving off in a new direction. The deflection is assumed to be very small. In particular, we consider a small part of the motion in which the photon moves a horizontal distance $dx = cdt$ while located at (x,y) relative to the center of the Sun. Note that $y \approx R$ and $r^2 = x^2 + y^2$. If the photon has energy E, it will have a "mass" of $m = E/c^2$, and a momentum of magnitude $p = E/c = mc$. To find the change of momentum in the y-direction, we use the impulse produced by the y-component of the gravitational force.

$$dp_y = F_y dt = -\frac{GMm}{r^2}\cos\theta\frac{dx}{c} = -\frac{GMm}{r^2}\frac{R}{r}\frac{dx}{c} = -\frac{GMmR}{c}\frac{dx}{\left(x^2+R^2\right)^{3/2}}$$

To find the total change in the y-momentum, we integrate over all x (the entire path of the photon). We use an integral from Appendix B-4.

$$\Delta p_y = \int_{-\infty}^{\infty} -\frac{GMmR}{c}\frac{dx}{\left(x^2+R^2\right)^{3/2}} = -\frac{GMmR}{c}\left.\frac{x}{R^2\left(x^2+R^2\right)^{1/2}}\right|_{-\infty}^{\infty} = -\frac{2GMm}{cR} = -\frac{2GMp}{c^2R}$$

The total magnitude of deflection is the change in momentum divided by the original momentum.

$$\Delta\theta = \frac{\left|\Delta p_y\right|}{p} = \frac{\frac{2GMp}{c^2R}}{p} = \boxed{\frac{2GM}{c^2R}}$$

(*b*) We use data for the Sun.

$$\Delta\theta = \frac{2GM}{c^2R} = \frac{2\left(6.67\times10^{-11}\,\frac{\text{N}\cdot\text{m}^2}{\text{kg}^2}\right)\left(1.99\times10^{30}\text{ kg}\right)}{\left(3.00\times10^{8}\text{ m/s}\right)^2\left(6.96\times10^{8}\text{ m}\right)}$$

$$= 4.238\times10^{-6}\text{ rad}\left(\frac{180^\circ}{\pi\text{ rad}}\right)\left(\frac{3600''}{1^\circ}\right) = \boxed{0.87^\circ}$$

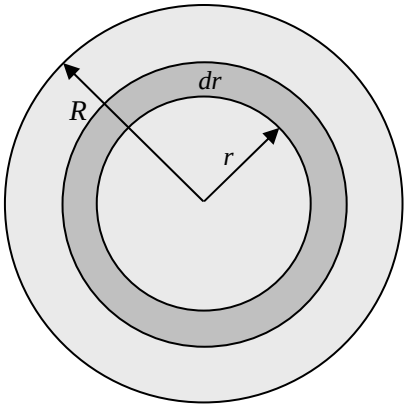
55. Because Venus has a more negative apparent magnitude, Venus is brighter. We write the logarithmic relationship as follows, letting m represent the magnitude and b the brightness.

$$m = k\log b \;;\; m_2 - m_1 = k\left(\log b_2 - \log b_1\right) = k\log\left(b_2/b_1\right) \;\rightarrow$$

$$k = \frac{m_2 - m_1}{\log\left(b_2/b_1\right)} = \frac{+5}{\log\left(0.01\right)} = -2.5$$



$$m_2 - m_1 = k\log\left(b_2/b_1\right) \;\rightarrow\; \frac{b_2}{b_1} = 10^{\frac{m_2-m_1}{k}} \;\rightarrow\; \frac{b_{\text{Venus}}}{b_{\text{Sirius}}} = 10^{\frac{m_{\text{Venus}}-m_{\text{Sirius}}}{-2.5}} = 10^{\frac{-4.4+1.4}{-2.5}} = \boxed{16}$$

56. If there are N nucleons, we assume that there are approximately $\frac{1}{2}N$ neutrons and $\frac{1}{2}N$ protons. Thus, for the star to be neutral, there would also be $\frac{1}{2}N$ electrons.

(*a*) From Eq. 40-12 and 40-13, we find that if all electron levels are filled up to the Fermi energy E_{F}, the average electron energy is $\frac{3}{5}E_{\text{F}}$.

$$E_{\text{e}} = N_{\text{e}}\left(\tfrac{3}{5}E_{\text{F}}\right) = \left(\tfrac{1}{2}N\right)\tfrac{3}{5}\frac{h^2}{8m_{\text{e}}}\left(\frac{3}{\pi}\frac{N_{\text{e}}}{V}\right)^{2/3} = \boxed{\frac{3}{5}\left(\frac{1}{2}N\right)\frac{h^2}{8m_{\text{e}}}\left(\frac{3}{\pi}\frac{N}{2V}\right)^{2/3}}$$

(*b*) The Fermi energy for nucleons would be a similar expression, but the mass would be the mass of a nucleon instead of the mass of the electron. Nucleons are about 2000 times heavier than electrons, so the Fermi energy for the nucleons would be on the order of 1/1000 the Fermi energy for the electrons. We will ignore that small correction.

To calculate the potential energy of the star, think about the mass in terms of shells. Consider the inner portion of the star with radius $r < R$ and mass m, surrounded by a shell of thickness dr and mass dM. See the diagram. From Gauss's law applied to gravity, the gravitational effects of the inner portion of the star on the shell are the same as if all of its mass were at the geometric center. Likewise, the spherically-symmetric outer portion of the star has no gravitational effect on the shell. Thus the gravitational energy of the inner portion–shel) combination is given by a form of Eq. 8-17, $dU = -G\dfrac{m\,dM}{r}$. The density of the star is given by $\rho = \dfrac{M}{\frac{4}{3}\pi R^3}$. We use that density to calculate the masses, and then integrate over the full radius of the star to find the total gravitational energy of the star.

$$m = \rho\left(\tfrac{4}{3}\pi r^3\right) = \frac{M}{\frac{4}{3}\pi R^3}\left(\tfrac{4}{3}\pi r^3\right) = M\frac{r^3}{R^3}$$

$$dM = \rho\left(4\pi r^2 dr\right) = \frac{M}{\frac{4}{3}\pi R^3}\left(4\pi r^2 dr\right) = \frac{3Mr^2}{R^3}dr$$

$$dU = -G\frac{m\,dM}{r} = -G\frac{M\dfrac{r^3}{R^3}\dfrac{3Mr^2}{R^3}dr}{r} = -\frac{3GM^2}{R^6}r^4 dr$$

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$U = \int_0^R \left(-\frac{3GM^2}{R^6} r^4 \right) dr = -\frac{3GM^2}{R^6} \int_0^R \left(r^4 \right) dr = -\frac{3GM^2}{R^6} \frac{R^5}{5} = \boxed{-\frac{3}{5}\frac{GM^2}{R}}$$

(*c*) The total energy is the sum of the two terms calculated above. The mass of the star is primarily due to the nucleons, and so $M = Nm_{\text{nucleon}}$.

$$E_{\text{total}} = E_{\text{e}} + U = \frac{3}{5}\left(\frac{1}{2}N\right)\frac{h^2}{8m_{\text{e}}}\left(\frac{3}{\pi}\frac{N}{2V}\right)^{2/3} - \frac{3}{5}\frac{GM^2}{R}$$

$$= \frac{3h^2}{80m_{\text{e}}}\left(\frac{M}{m_{\text{nucleon}}}\right)\left(\frac{3}{\pi}\frac{M}{2m_{\text{nucleon}}\,\frac{4}{3}\pi R^3}\right)^{2/3} - \frac{3}{5}\frac{GM^2}{R} = \boxed{\frac{9^{2/3}3h^2M^{5/3}}{320\pi^{4/3}m_{\text{e}}m_{\text{nucleon}}^{5/3}R^2} - \frac{3}{5}\frac{GM^2}{R}}$$

Let $a = \dfrac{9^{2/3}3h^2M^{5/3}}{320\pi^{4/3}m_{\text{e}}m_{\text{nucleon}}^{5/3}}$ and $b = \dfrac{3}{5}GM^2$, so $E_{\text{total}} = \dfrac{a}{R^2} - \dfrac{b}{R}$. We set $dE_{\text{total}}/dR = 0$ to find the equilibrium radius.

$$\frac{dE_{\text{total}}}{dR} = -\frac{2a}{R^3} + \frac{b}{R^2} = 0 \quad \rightarrow \quad R_{\text{eq}} = \frac{2a}{b} = \frac{2\dfrac{9^{2/3}3h^2M^{5/3}}{320\pi^{4/3}m_{\text{e}}m_{\text{nucleon}}^{5/3}}}{\dfrac{3}{5}GM^2} = \boxed{\frac{9^{2/3}h^2}{32\pi^{4/3}GM^{1/3}m_{\text{e}}m_{\text{nucleon}}^{5/3}}}$$

We evaluate the equilibrium radius using the Sun's mass.

$$R_{\text{eq}} = \frac{9^{2/3}h^2}{32\pi^{4/3}GM^{1/3}m_{\text{e}}m_{\text{nucleon}}^{5/3}}$$

$$= \frac{9^{2/3}\left(6.63\times10^{-34}\,\text{J}\bullet\text{s}\right)^2}{32\pi^{4/3}\left(6.67\times10^{-11}\,\dfrac{\text{N}\bullet\text{m}^2}{\text{kg}^2}\right)\left(2.0\times10^{30}\,\text{kg}\right)^{1/3}\left(9.11\times10^{-31}\,\text{kg}\right)\left(1.67\times10^{-27}\,\text{kg}\right)^{5/3}}$$

$$= 7.178\times10^6\,\text{m} \approx \boxed{7.2\times10^3\,\text{km}}$$

57. There are *N* neutrons. The mass of the star is due only to neutrons, and so $M = Nm_{\text{n}}$. From Eqs. 40-12 and 40-13, we find that if all energy levels are filled up to the Fermi energy E_{F}, the average energy is $\frac{3}{5}E_{\text{F}}$. We follow the same procedure as in Problem 56. The expression for the gravitational energy does not change.

$$E_{\text{n}} = N_{\text{n}}\left(\tfrac{3}{5}E_{\text{F}}\right) = \left(N\right)\tfrac{3}{5}\frac{h^2}{8m_{\text{n}}}\left(\frac{3}{\pi}\frac{N}{V}\right)^{2/3} = \left(\frac{M}{m_{\text{n}}}\right)\frac{3h^2}{40m_{\text{n}}}\left(\frac{3}{\pi}\frac{M}{\frac{4}{3}\pi R^3 m_{\text{n}}}\right)^{2/3} = \frac{3\left(18\right)^{2/3}h^2M^{5/3}}{160\pi^{4/3}m_{\text{n}}^{8/3}R^2}$$

$$E_{\text{total}} = E_{\text{n}} + U = \frac{3\left(18\right)^{2/3}h^2M^{5/3}}{160\pi^{4/3}m_{\text{n}}^{8/3}R^2} - \frac{3}{5}\frac{GM^2}{R}$$

Let $a = \dfrac{3\left(18\right)^{2/3}h^2M^{5/3}}{160\pi^{4/3}m_{\text{n}}^{8/3}}$ and $b = \dfrac{3}{5}GM^2$, so $E_{\text{total}} = \dfrac{a}{R^2} - \dfrac{b}{R}$. We set $dE_{\text{total}}/dR = 0$ to find the equilibrium radius.

© 2009 Pearson Education, Inc., Upper Saddle River, NJ. All rights reserved. This material is protected under all copyright laws as they currently exist. No portion of this material may be reproduced, in any form or by any means, without permission in writing from the publisher.

$$\frac{dE_{\text{total}}}{dR} = -\frac{2a}{R^3} + \frac{b}{R^2} = 0 \quad \rightarrow \quad R_{\text{eq}} = \frac{2a}{b} = \frac{2\dfrac{3(18)^{2/3} h^2 M^{5/3}}{160\pi^{4/3} m_{\text{n}}^{8/3}}}{\dfrac{3}{5} GM^2} = \frac{(18)^{2/3} h^2}{16\pi^{4/3} GM^{1/3} m_{\text{n}}^{8/3}}$$

We evaluate the equilibrium radius for a mass of 1.5 solar masses.

$$R_{\text{eq}} = \frac{(18)^{2/3} h^2}{16\pi^{4/3} GM^{1/3} m_{\text{n}}^{8/3}}$$

$$= \frac{18^{2/3} \left(6.63\times10^{-34}\,\text{J•s}\right)^2}{16\pi^{4/3}\left(6.67\times10^{-11}\,\dfrac{\text{N•m}^2}{\text{kg}^2}\right)\left[1.5\left(2.0\times10^{30}\,\text{kg}\right)\right]^{1/3}\left(1.67\times10^{-27}\,\text{kg}\right)^{8/3}}$$

$$= 1.086\times10^4\,\text{m} \approx \boxed{11\,\text{km}}$$

58. We must find a combination of *c*, *G*, and $\hbar$ that has the dimensions of time. The dimensions of c are $\left[\dfrac{L}{T}\right]$, the dimensions of *G* are $\left[\dfrac{L^3}{MT^2}\right]$, and the dimensions of $\hbar$ are $\left[\dfrac{ML^2}{T}\right]$.

$$t_P = c^\alpha G^\beta \hbar^\gamma \quad \rightarrow \quad [T] = \left[\frac{L}{T}\right]^\alpha \left[\frac{L^3}{MT^2}\right]^\beta \left[\frac{ML^2}{T}\right]^\gamma = [L]^{\alpha+3\beta+2\gamma}[M]^{\gamma-\beta}[T]^{-\alpha-2\beta-\gamma}$$

$$\alpha + 3\beta + 2\gamma = 0\ ;\ \gamma - \beta = 0\ ;\ -\alpha - 2\beta - \gamma = 1 \quad \rightarrow \quad \alpha + 5\beta = 0\ ;\ \alpha = -1 - 3\beta \quad \rightarrow$$

$$-5\beta = -1 - 3\beta \quad \rightarrow \quad \beta = \tfrac{1}{2}\ ;\ \gamma = \tfrac{1}{2}\ ;\ \alpha = -\tfrac{5}{2}$$

$$t_P = c^{-5/2} G^{1/2} \hbar^{1/2} = \sqrt{\frac{G\hbar}{c^5}} = \sqrt{\frac{\left(6.67\times10^{-11}\ \text{N•m}^2/\text{kg}^2\right)\dfrac{1}{2\pi}\left(6.63\times10^{-34}\,\text{J•s}\right)}{\left(3.00\times10^8\ \text{m/s}\right)^5}} = \boxed{5.38\times10^{-44}\,\text{s}}$$
